The Eastman Kodak Company has developed a co-operative, profit sharing plan which is recommended to all industries. Questions of all kinds are discussed between the managers and the men, but Mr. Eastman has gone the usual plan of this kind one better. He has stated that the co-operative theory is all right but a few extra dollars in the pay envelope of the workers make for a real co-operation. If the Kodak Company makes a profit so that the shareholders receive dividends, the workers, or the men responsible for the production, also receive a dividend. The output of the Kodak plant has increased 25 percent under this plan and there has been no loss to stockholders or workers due to strikes.

Heroic efforts have been made by certain private owners and by the United States Shipping Board to keep American ships in operation but they have failed so far in enlisting the real co-operation of the sea-going personnel. Establishing clubs and associations of their own, which are poorly patronized and little thought of, will not bring to the operators the co-operation which they need so badly at this time. The shipping men of this country have many very serious problems to consider but they should not neglect the problems of personnel, for it will be almost impossible for the steamship business to prosper without the proper kind of men working harmoniously with the operators aboard the ships.

One of the most feasible ways to establish this co-operation would be to recognize the organizations which the men have built up and by making agreements with the men through these organizations and living up to such agreements after they are made. If the proper sort of co-operation had been in existence between the steamship owners and the sailors' union, Andrew Furuseth, in all probability, would not have appeared in Washington to wage such a strenuous fight against the ship subsidy bill, and the other associations which so heartily supported this measure would have been in a better position, financially and otherwise, to render this very necessary legislation more effective aid.

Economies Practiced by Successful British Shipowners

English Correspondent Outlines Methods of Effecting Operating Savings—Note Ease of Obtaining Concessions from Parliament

By Our British Correspondent

ECONOMY is at all times a praiseworthy endeavor, but never more so than when the fight goes to those who are able to effect a saving where others cannot—or at all events do not. I propose, in the first part of this article, therefore, to place on record some of the essentials leading to economies as practiced by successful shipowners. It should first be made clear, however, that there is no royal road to economy, that is to say, it is not an automatic process, but is a question on which considerable time and protracted deep-thinking must be expended.

One of the most noteworthy economies is in regard to insurance, and especially in connection with particular average. Only those owners with a good record extending over a number of years are able to arrange their insurance upon the cheapest lines, and even then much depends upon the age of the steamers. Owners possessed of a fleet of modern vessels are in a far better position than those who are handicapped with steamers of a greater age. Obviously it is a dangerous procedure for shipowners possessing, say, one or two vessels to run them unless fully covered against all risks, but, in the case of the larger ownerships, the particular average risk, varying from 50 percent to the whole of it, is, in fact, successfully undertaken. They have in the past probably been able to build up a substantial reserve fund, enabling them to look with equanimity upon the risk involved by running part or the whole of their own particular average, and which risk, spread over a fleet of, say, fifteen or twenty modern steamers, is a fair and reasonable one to take. With a company owning a single ship, or two or three ships, this is a risk or liability that cannot be legitimately undertaken, otherwise they might be faced at any moment with liabilities in consequence of particular average damage far beyond their resources. But it is quite another question when the risk is spread over a large fleet, and, without mentioning names, it is permissible to say that, as I have indicated, this procedure is engaged in by prominent shipowners in the United Kingdom.

Dispensing with freight advances is another direction in which important economies may be effected, but this is a difficult matter in such unpropitious times as the present, when owners in many cases have little option but to sacrifice appreciable sums in commissions.

CONFINING VESSELS TO PARTICULAR TRADES

Then, owners may economize as a result of keeping their vessels in one trade over a series of voyages, and, furthermore, of confining the boats to the trades for which they are

most suitable. For example, if a vessel is thoroughly fitted up for carrying grain, it is a paying proposition on economical grounds to confine her trading as entirely as possible to the carriage of grain cargoes. I have known of many cases where steamers have been diverted into other trades, probably by force of circumstances, and on returning to the grain trade owners have been staggered by the expense incurred in replacing shifting boards and grain fittings, especially in the North Atlantic trade. This is obviously a very real economy, but, as in the case of freight advances, it is again a question of owners being in a position to pick and choose.

Periodical surveys, too, should be watched in the matter of the carriage of certain cargoes, or heavy additional expense will be incurred in "passing through." In the British North America trade, many owners effect substantial economies by the payment of the extra premium of insurance immediately on the opening of the season, thereby enabling them to spread the premium over the season and work in several trips at the cost of one.

SUPERFLUOUS BUNKERS

Then there is the question of economies to be effected by ascertaining that the quantity of bunkers carried is not superfluous. In one case within my recollection there was a discrepancy of nearly 100 tons in the quantity of bunkers actually carried and the returns of the total deadweight (cargo and bunkers) which were sent to the owners each voyage in accordance with instructions. The owners were for an appreciable time unable to lay their finger on the "spot," but eventually did so, incidentally discovering that the engineer, in order to be on the safe side, had been "nursing" a superfluous 100-ton margin on each voyage. He was "fired," and the carriage of bunkers was placed on an economic footing.

In regard to the general question of coal bunker economies in the matter of purchases, it was the practice years ago to contract ahead for quantities to cover several months, but the policy in these days is, owing to various causes, to live almost from hand to mouth. It is, on the face of it, an unbusinesslike method, but, with the present-day ups and downs, the measure has been found to justify its incidence.

CLOSE SURVEILLANCE OF STORES A PAYING PROPOSITION

Stores is another branch in which keen surveillance is imperative, and in which the expenditure of a salary to a sea-going man in the shipowner's office—usually a captain or chief engineer who has been many years in the service—has proved to be a paying proposition. The larger companies,

of course, possess in most cases a marine superintendent, and are, therefore, in safe hands—if they possess the right type of man. But in the smaller fleets down to single-ship and two-ship concerns, where the appointment of a marine superintendent in the generally accepted sense of the term is impracticable, it undoubtedly pays to have a man in the office who can point his finger to items in the captain's inventory renewals and say: "This is unnecessary," or "That is essential." The average landsman would be "at sea" with such a list before him, but not so the man who has been to sea and who knows to a rope what is required and what is not.

In the matter of shelter deck vessels there is also scope for economy, for, unless intelligence is shown in the selection of cargo, this type of vessel is at some economical disadvantage to a single deck vessel. It is a fact that many shelter deck steamers seldom run in the trades for which they are specially suited, but here again force of circumstances is probably the deciding factor. It is significant, however, that keen and discerning time charterers, who study expenditure in every detail, decline to take double decked steamers where a single decker is preferable.

CONCESSION IN SHIPPING FEES BILL SECURED

A direction in which British shipowners as a body have effected an important economy since my contribution appeared in this magazine a month ago is in regard to the short and sharp fight around the provisions of the Shipping Fees Bill. This measure, embracing charges for such services as the measurement of tonnage, surveys, and so on, imposed, in its original form, an annual charge on shipowners of £420,000 per annum, as against the £90,000 yearly charge hitherto incurred. But, as a result of representations made to the President of the Board of Trade by the Shipowners' Parliamentary Committee, working in conjunction with the Chamber of Shipping of the United Kingdom, a substantial concession has been secured, and in the bill as amended the annual charge is reduced to half the original sum, that is £210,000, or £120,000 per annum more than shipowners have thus far paid. The bill in its amended form is now receiving the approval of shipowners, and the measure will, there is little reason to doubt, eventually find its way to the Statute Book. The burden of the charges may be gaged from the following new maximum scale provided in the schedule to the bill:

MEASUREMENT OF MERCHANT SHIPS

	£	s.	d.
Vessels of 50 tons gross and under	2	0	0
Over 50 tons gross and under 100 tons	4	0	0
Each additional 100 tons or part of 100 tons above 1,000 up to 10,000	1	0	0
Each additional 100 tons or part of 100 tons above 10,000	0	10	0

PASSENGER STEAMER'S CERTIFICATE

Steamer not exceeding 50 tons gross	4	0	0
Exceeding 50 and not exceeding 100 tons gross	8	0	0
Exceeding 100 and not exceeding 300 tons gross	12	0	0
Exceeding 300 and not exceeding 600 tons gross	15	0	0
For every additional 300 tons or part of 300 tons above 600 an additional	3	0	0

SURVEY OF EMIGRANT SHIPS

For ships holding valid passenger certificates:			
Ordinary survey	12	0	0
Special survey	20	0	0
For ships not holding valid passenger certificates an additional fee			

REGISTRATION, TRANSFER AND MORTGAGE

On initial Registry:			
Vessel not exceeding 25 tons gross ..	2	0	0
Exceeding 25 and not exceeding 50 tons gross ..	2	10	0
Exceeding 50 and not exceeding 100 tons gross ..	3	0	0
Exceeding 100 and not exceeding 200 tons gross ..	4	0	0
With £1 for every additional 100 tons or fraction of a 100.			

On transfer, transmission, registry anew, transfer of registry, mortgage, and transfer of mortgage. According to the gross tonnage represented by the ships or shares of ships transferred, etc.

	£	s.	d.
Not exceeding 10 tons	0	5	0
10 tons and not exceeding 20	0	10	0
20 " " " 30	0	15	0
30 " " " 40	1	0	0
40 " " " 50	1	5	0
50 " " " 75	1	10	0
75 " " " 100	1	15	0
100 " " " 125	2	0	0
A further fee of 5s. for every additional 50 tons, or part or 50 tons, up to 500 tons, after which for every 100 tons, or part of 100 tons	0	5	0

New Development in Marine Boilers Designed to Increase Economy of Operation

MARINE boilers have certain limitations which are not found in land plants; therefore, a boiler to meet marine conditions must meet the limitations aboard ship. The principal requirements of marine boilers different from that found in land practice are space, weight, steady steam demand, feed water and to some extent character of the personnel which is usually not as well trained as the average shore engineer.

In land plants it is usually customary to have spare equipment to meet the varying load conditions found during the peak loads, but this is not necessary or desirable aboard ship. First because the load or steam demand is fairly constant, and second, space and weight available prohibit spare boilers. It is desirable, therefore, to design marine boilers for a fixed steam capacity which will give the maximum economy and to operate them at that capacity constantly while at sea.

Owing to there being no spare boiler equipment, reliability is the most important factor in a marine boiler. Both weight and first cost have in the past been sacrificed to reliability, as is evidenced by the great number of Scotch marine boilers that have been used. Many attempts have been made to use watertube boilers, and in recent years this type of boiler has been more frequently installed in spite of the fact that it requires a better grade of feed water and more intelligent operation than the older Scotch marine type.

NEW TYPE OF SUPERHEATER AND ECONOMIZER

To meet marine conditions and obtain the same economy which is now found in the large central stations ashore, a new development in marine boilers has recently been brought out by the Foster Marine Boiler Corporation. They have improved their boiler with a new type of superheater and economizer arranging all three devices in one compact steel casing as shown in sectional side elevation, Fig. 1.

The principal change in the boiler heating surface proper has been made in reducing the height of the tube bank and increasing it in width, also in depth. This gives a low wide boiler, adds approximately 50 percent to the water storage in the boiler proper, giving it nearly the same water reserve as the Scotch marine type. Also by lengthening the tubes a greatly enlarged furnace volume is obtained, and the space available aboard ship is taken up more efficiently. Another interesting feature of the heating surface is the opening up of the lower rows of boiler tubes to allow the radiant heat to penetrate further into the tube bank, thus reducing the load on the lower row of tubes which, it is claimed, will overcome most of the present difficulties found with burning and blistering of these tubes when scaled. This is clearly shown in Fig. 2.

The general design of baffling as shown in Fig. 1 is the well known Foster steel plate type in which the baffles are cooled by the boiler tubes top and bottom. With this form

of baffling, it is claimed, if any repairs should be required in the lower row tubes, there will be no repairs or renewals required by the baffling.

The furnace design is radically different from present practice as a Foster radiant heat type superheater is installed in the rear wall, which enables any degree of superheat desired to be obtained and reduces considerably the furnace temperature. Repairs in the brickwork furnace lining will be reduced, it is claimed, due to the cooling effect of this furnace wall superheater in conjunction with the extra tube surface exposed in the lower rows of the boiler.

BOILER IS PRIMARILY AN EVAPORATOR

The steam boiler should be primarily an evaporator and not a combination of feed water heater and evaporator. Many land plants have installed economizers to add the required sensible heat to the feed water up to or close to the

will be increased, it is claimed, as the waste gases leaving the economizer will be from 250 to 300 degrees Fahrenheit instead of from 500 to 600 degrees as found in present marine boiler practice. Assuming an average stack temperature of 550 degrees as now practiced and 300 degrees with the new boiler, there will be an approximate fuel saving of $7\frac{1}{2}$ percent, as generally it has been shown by experiment that there is a reduction of 1 percent in fuel used for each 30 to 35 degrees reduction in stack temperature. There will be a further gain due to the heat absorbed by the superheater. This gain, through increased or higher superheat than is now used, will be mainly shown in the engine or turbine where all of the superheat appears in useful work. Reducing the stack gases to the lower temperature possible with this new boiler unit will not only help to increase the economy when proper combustion is maintained in the furnace, but in the case of inefficient operation such as when

Fig. 1.—Side Elevation (Section Through A-A, Fig. 2) of Foster Marine Watertube Boiler with Superheater and Economizer

temperature of the steam, which leaves to the boiler only the work of adding the latent heat of vaporization. The boiler heating surface is best adapted for evaporating work only, and the separate heating surface of an economizer is best adapted for reducing the temperature of the stack or waste gases to the minimum point and adding the sensible heat of the water before evaporating. This splitting up of the heat absorbing surfaces into two parts, a boiler and an economizer, results in a material gain in economy at a moderate increase in cost and, if the water velocity in the economizer is kept at its proper rate, most of the scale forming matter, such as carbonates, etc., will be deposited on the economizer surface as a soft mud, and will not pass into the boiler where it would be baked on in the lower row tubes as a hard scale. The addition of the economizer also gives a large storage of hot water available for immediate use which results in steadier steaming and also helps the water reserve of the complete unit. This new Foster combined unit with its economizer has a larger water storage, it is claimed, than the present Scotch marine boiler.

The efficiency of this new Foster steam generating unit

Fig. 2.—End Elevation (Section Through B-B, Fig. 1) of New Foster Marine Boiler, Designed for 250 Pounds Working Pressure and 150 Degrees F. Superheat

large quantities of excess air are used will tend to reduce the losses of inefficient operation due to more of the heat in the excess air being absorbed by the economizer before passing to the stack. In other words, the losses due to inefficient operation will not be as great owing to the final temperatures being nearer to the original temperature of the air used for combustion than is found in present practice.

BOILER EFFICIENCIES

The new Foster improved boiler unit, it is claimed, will have an efficiency of from 85 to 90 percent depending upon the fuel used and the completeness of combustion. Its weight and space required will be approximately the same as the present Scotch marine type, its gas outlet being at about the location of that of the Scotch type which lends itself to the shortest flue to a central stack.

Marine fuels are more expensive than in the past and, therefore, fuel economy is of greater importance than before the war. With approximately 600 pounds pressure and 250 degrees superheat a modern marine steam plant, it is claimed, can produce power for the same fuel cost as a Diesel engine.

Effect of the Propeller on Economical Ship Operation

By E. A. Stevens, Jr.*

TO obtain economical results, two things are required: first, to reduce the fuel per indicated (or shaft) horsepower, and, second, to reduce the power required to drive the ship at the desired speed. The result of the two is to get the greatest mileage per ton of fuel. In many cases the second point is overlooked and, when the machinery is being operated quite efficiently, it is the more important of the two.

Two things can be done to reduce the power required to drive a ship; one is to keep the underwater body of the ship clean, the second is to make a change in the propeller where it is not giving good results. By making this change, the speed can often be materially increased and at the same time the fuel consumed per day reduced.

WHERE RECIPROCATING ENGINES WERE INSTALLED IN PLACE OF TURBINES

During the war a large number of ships were built that were intended to be driven by geared turbines with a propeller speed of 90 revolutions per minute. In many cases reciprocating engines were installed in place of turbines, but no change was made in the propeller or the position of the tail shaft. The result was that the engines were not able to operate under economical conditions, and, in order to prevent them from running at too high a number of revolutions, they were never allowed to obtain full power.

In some cases the pitch was increased in order to correct this fault, until a new propeller could be made and installed. This increasing of the pitch, however, made it necessary for the engines to deliver more power as the propeller was working in what is generally known as "cavitation" of the kind that Admiral Dyson calls "dispersal of the thrust column." However, the total fuel consumed was, in some cases, less, as the engines were working under more favorable conditions. The wear and tear was also reduced. In most of these cases the location of the shafting was such that it was impossible to put on a wheel of the proper diameter, and therefore broad tip blades had to be used.

ILLUSTRATIONS

Example 1. This ship was fitted with a propeller of the following characteristics: Diameter, 17 feet; pitch, 15 feet 9 inches; projected area ratio, .342; number of blades, 4. From the trial results it was discovered that this wheel was working in cavitation so a new wheel was designed. As the diameter was limited to 17 feet 6 inches it was necessary to broaden the blade tips. The new wheel had four blades, a pitch of 15 feet and a projected area ratio of .36.

The maximum speed obtained on the trial with the old propeller was 9.41 knots with 2,126 indicated horsepower, while with the new wheel it is estimated that this speed could be obtained with 1,930 indicated horsepower, a saving of $9\frac{1}{4}$ percent. To maintain a sea speed of 10 knots it is estimated that with the old wheel the power required would

It is not generally realized what a significant part the propeller plays in the efficient and economical operation of ships. It is just as important **to reduce** the horsepower required at a given speed and draft as it is to reduce the fuel burned per indicated horsepower. Change in propeller sometimes means a saving of 15 percent in the fuel. The examples given in this article are good illustrations of the savings that can be effected by installation of properly designed propeller wheels.

be 3,080 indicated horsepower (which was impossible with the boilers and engine while only 2,610 indicated horsepower would be required with the new propeller, this being a saving of $15\frac{1}{4}$ percent.

Example 2. This ship was originally fitted with a four-bladed wheel of 16 feet diameter, 14 feet 6 inches pitch and a projected area ratio of .368. With this wheel she made 8.23 knots at sea in smooth water and burned 42 tons of coal in 24 hours. The above wheel was replaced with a four-bladed

one with broad tips, the diameter of which was 17 feet, pitch 15 feet 3 inches and the projected area ratio was .392. A speed of 9.25 knots was obtained with this wheel while the coal burned was reduced to 38 tons per diem. The saving in fuel was $9\frac{1}{2}$ percent, while the effective horsepower delivered by the propeller was increased about 40 percent.*

Example 3. This ship was fitted with a four-blade propeller, the pitch of which was 19 feet. On the trial trip a speed of 11.19 knots was obtained with 2,695 indicated horsepower and 69.75 revolutions per minute. The mean referred pressure was 39.2 pounds. As this wheel was working in cavitation a reduction of the pitch to 17 feet would have reduced the indicated horsepower required to 2,555, increased the revolutions to 74 and reduced the mean referred pressure to 35.2 pounds. This would mean that the engine could be run with advanced cut off in the high pressure cylinder, thereby reducing the water rate, while the revolutions would not be excessive. At sea the saving in power would be even greater than that mentioned above.

Although examples 1 and 3 are estimates, it is believed that the actual results will be practically as shown. These were calculated by the Dyson method of propeller analysis and design which the writer has found to be quite accurate. Some of his investigations were shown in a paper presented last fall at the Transactions of the Society of Naval Architects and Marine Engineers entitled, "The Application of Dyson's Method to Propellers of Ocean Going Merchant Ships."†

SAVING CAN OFTEN BE MADE BY CHANGING PITCH

Very often a saving can be made in the fuel bill by changing the pitch, thereby increasing or decreasing the revolutions without decreasing the power required to drive the ship. This was done in the case of a geared turbine driven cargo ship where the pitch was reduced from 14 feet 6 inches to 13 feet, which resulted in a saving of 10 percent in the fuel, while the power required was about the same for the same speed and draft.

Another case is that of an 8,800-ton deadweight cargo ship that was fitted with a very large reciprocating engine, the low pressure cylinder of which had a diameter of 80 inches and a stroke of 48 inches. The propeller was a four-bladed wheel of 17 feet diameter, 15 feet 9 inches pitch and a projected area ratio of .34. The power re-

†Reprinted in MARINE ENGINEERING AND SHIPPING AGE, April, 1923.

Removing Propellers on Twin Screw Passenger Steamer in Dry Dock

quired to drive this ship at a sea speed of $10\frac{1}{2}$ knots was about 2,620 indicated horsepower, and the revolutions per minute, about 77.5. This would require about 27.9 pounds mean referred pressure. It was not considered advisable to run this ship at a greater speed on account of the high number of revolutions. As no larger propeller could be installed a broad tip wheel is being made with the same diameter as the old one but with 16-feet 9-inch pitch and a projected area ratio of .39.

It is estimated that with this propeller 2,680 indicated horsepower would be required to obtain $10\frac{1}{2}$ knots at sea, while the revolutions would be about 71.5 and the mean referred pressure 30.8 pounds. With this wheel a speed of .1 knots could be obtained with about 75 revolutions per minute. While the power required for $10\frac{1}{2}$ knots is increased about $2\frac{1}{2}$ percent the engine will be working under better condition, and the fuel burned will probably be much less, while the wear on the engine will be considerably reduced.

TWO COMMON FALLACIES

Before closing, I wish to call attention to two very common fallacies. The first is that low slip means a high efficiency. While this is true in some cases, it is not always so. For instance, two ships, one having finer lines than the other, both having the same power and revolutions, the one with the finer form will run with more slip while the propulsive efficiency will be greater as the power augment factor (generally called the thrust deduction factor) would be less. In the case of high speed propellers, increasing the diameter will result in decreasing the slip, but the

efficiency will decrease after a certain diameter is reached.

The second fallacy is that a pitch ratio of over unity is necessary in order to obtain high efficiency. While it is true that high propulsive efficiencies are generally found where the pitch ratio is over unity, it is not due to this but to the fact that the hull in such cases is so shaped that the flow of water to the propeller is not disturbed enough to materially increase the power required had the propellers been operating in undisturbed waters. It has been mentioned on more than one occasion that in both destroyers and freight steamers where the pitch ratio is about 0.8 that the propulsive efficiency is not generally over 53 to 54 percent.* This is true, but it should not be overlooked that there is a difference between propulsive efficiency and the propeller efficiency.

In the case of the destroyer the power augment factor is unity, therefore the propulsive efficiency is the same as the propeller efficiency. The low efficiency, however, is not due to the low pitch ratio, but to the high tip speed and thrusts. In the case of the freight steamer the low efficiency is due to the effect that the hull has on the flow of water to the propeller which, in many cases, increases the power at least 25 percent over that required if the propeller was not so affected, so, if the propulsive efficiency in this case is 54 percent, the propeller efficiency would be 67.5 percent, which is about as good as can be expected. The pitch ratio from what has been said can be considered an incident and not a cause.

* Propulsive efficiency = $E. H. P. \div I. H. P.$; if $E. H. P. \div S. H. P.$ is used, these figures would be 57.6 to 58.7.

An Economizer That Requires No Outlay

High Grade Lubricating Oils Intelligently Used in the Engine Room Will Promote Efficiency and Cut the Operating Bill

THE cost of poor marine lubrication is disastrous. An attempt to economize on the first cost of lubricating oil for ship machinery is about the most expensive mistake in which an operator can indulge. It is a fuel waster, a speed destroyer, a booster of repair bills and a loser of profits.

When a turbine driven vessel such as the *Robin Adair* is able to show a log of 170,000 miles on the low speed unit where the tooth pressure is 1,000 pounds per lineal inch without appreciable wear, the machinery must have been properly lubricated.

One hundred and eighty thousand miles without replacements of any kind has been recorded by the double reduction geared turbine ship *Niels Nielson*. Proper oil and efficient operating methods are entirely responsible for such a showing.

The adoption of a high grade lubricant will effect a direct saving in consumption as evidenced by the cost sheet of the motorship *Renfield* where the oil consumption was reduced from 28 gallons of lubricating oil a day to 14 by a change in the quality of oil used.

The record of the trial trip and maiden voyage of the steamship *Alleghany* of the Furness Withy Line contains an interesting example of the results possible from the adoption of efficient engine room lubricating methods and quality oils. On her trial trip this ship exceeded her contracted speed, making 14.7 knots, developing about 3,000 horsepower. From Liverpool to Boston on her first run she averaged 14 knots and consumed only 4 gallons of lubricating oil per day.

How do these ships get results—what are the methods and the oils used in efficiency performances of this nature?

ONLY SMALL QUANTITIES OF OIL NEEDED

If all the oil used on marine equipment accomplished its function without waste, comparatively small quantities would be necessary. Oiling at regular intervals should be the rule of the staff. When fed by hand the oil film will cling to bearings and continue to perform its function for a limited period. With an automatic feed, regulated carefully, the consumption can be kept low while accomplishing a maximum effect. In circulating systems where repeatedly purified by mechanical or filtration methods, lubricants last indefinitely, requiring but small quantities for replacement, provided the quality of the oil is correct for this service. With the idea of adequate lubrication without waste in mind, the high grade oils for given uses become the most economical.

The first cost of a lubricant is of comparatively minor importance, however, when the effect of lubrication on the machinery is considered. The slightest delay in port made necessary by burned out bearings or any other cause due to faulty lubrication rapidly overtops the lubricating oil bill covering a long period.

PLACES WHERE FRICTION LOSSES ARE GREATEST

In reciprocating engines where the problem is largely one of external lubrication, the opportunity for conserving oil through a careful study of oiling methods is great. From the engine to the propeller, friction losses occur in the piston, packing glands, crossheads, valve gears, eccentrics, main bearings, crank pins, thrust bearings, line shaft bearings, stern tube stuffing box and stern tube bearings. The prob-

lems of maintaining bearing adjustments, piston clearances spring tension and the like at exactly the correct point to prevent overheating and, at the same time, eliminate pounding are too well understood to require comment. It is sufficient to say that the maintenance of shaft alinement and careful adjustment of moving parts is the first duty of the staff. On the matter of selecting the proper lubricant and feeding it to accomplish the best results there is a vast field for the improvement of methods now generally employed.

METHODS OF INTERNAL LUBRICATION OF RECIPROCATING STEAM ENGINES

The internal or cylinder lubrication of reciprocating engines is accomplished by a variety of methods—hand oiling, tallow cups, hydrostatic lubrication and mechanical forced feed instruments.

The inefficiency of oil cups as a method of cylinder lubrication is evident. The cup is filled, the cover replaced, the cock at the base opened and the oil permitted to flow into the cylinder or the steam chest. This system lacks regularity, results in a waste of lubricant and demands frequent attention. With hand swabbing, using cylinder oil, the rods and packings are well lubricated but this method is hardly satisfactory for cylinder and valve lubrication. The practice of swabbing the rods requires regularity and only with an oil of absolutely correct quality will the lubrication of an engine by this method be satisfactory.

Such an oil must have great spreading ability, the properties necessary for maintaining a lubricating and sealing oil film under high pressure and temperature, the ability to resist the washing effect of cylinder condensation, the quality to furnish maximum lubrication with a small supply, non-carbonizing properties and the ability to quickly separate from condensed steam in order to avoid boiler troubles.

If oil of the same quality were introduced into the steam line by means of a mechanical force feed lubricator in quantities much smaller than those required for the inefficient hand swabbing method, correct lubrication of all parts would be assured without danger of introducing any oil into the boiler.

EFFECTS OF VARIOUS LUBRICATING METHODS

For use when starting an engine or when there is a tendency for internal parts to squeak, hand oil pumps are often installed. With this method more oil than is actually required is pumped into the engine with the usual result that the excess finds its way into the condenser with the exhaust steam. The hand pump must always be used with careful judgment.

The hydrostatic lubricator is connected to the main steam line and depends for its action on the replacement of oil with condensate from the steam line. This type of lubricator must be started and stopped by hand. It is not absolutely regular or uniform in its delivery of oil, as changes in temperature, leakage or an obstruction in the delivery passage alter the rate of feed. It must be kept under observation to insure good results.

Force feed lubrication is accomplished by the use of a mechanical lubricator, consisting of an oil reservoir and a small plunger pump for each oil feed, operated by a lever and ratchet motion which is attached to some moving part of the engine. There is a sight feed glass by which the rate of feed may be observed. There is also some means by

NOTE—The information used in the preparation of this article was supplied by the Vacuum Oil Company and the Texas Oil Company of New York.

which the stroke of each plunger may be regulated to increase or decrease the feed.

When a good type of mechanical lubricator is selected, this method of lubrication is automatic and absolutely regular in its delivery of oil. The stroke may be adjusted to deliver any desired quantity of oil and by trial a very high degree of economy can be attained. Temperature changes do not influence the feed of a good mechanical lubricator.

TYPES OF OIL BEST ADAPTED TO PROPELLING MACHINERY

For the lubrication of the marine steam engine two oils are necessary, one for steam cylinders, valves, valve and piston rods and packing glands, and one for crosshead guides, wrist pins, crank pins, main bearings and valve gear.

The high steam temperature and pressures employed, require the use of a heavy bodied cylinder oil which must form a lubricating and sealing film, even when moisture is present.

Adhesion to the friction surfaces in the presence of moisture is most commonly obtained by compounding the oil. In the case of marine engines, however, compounded oils are generally considered objectionable because they do not readily separate from the water of condensation in the hot-well, in which case the boilers become coated internally with oil, resulting in poor heat transfer and overheated metal. For this reason a highly refined mineral cylinder oil is generally used which has been manufactured from selected crudes by methods adapted to develop its adhesive and lubricating characteristics to the greatest possible degree.

For the lubrication of the external parts of the marine engine, friction and wear are reduced to a minimum and the bearing temperatures are kept within reasonable limits best by the use of a high quality heavy bodied compound lubricating oil. While it is sometimes attempted to describe such an oil by specifications, giving the viscosity and other physical characteristics, the only satisfactory basis for the selection of an oil for this purpose is the established service record of the oil. Manufacturers who specialize in high grade lubricating oils may be consulted to advantage and it is generally safest to accept the results of their extended experience in the selection of the oil.

Although the oils selected in this way may cost more per gallon than would another oil, correct lubrication can be attained by their economical use, resulting in less expensive lubrication in the long run than by the use of a cheaper and less suitable lubricant. A further and greater return to the operator is the decrease in repairs and increase in useful life of the engine, as a result of correct lubrication.

STUDY OF WICK FEED OILERS PROFITABLE

In connection with the lubrication of bearings and external engine parts, the opportunity for improvement in the use of wick feed oilers is considerable and in a large measure depends on the work of the individual engineers. As with other methods, the rate of feed should be maintained practically constant and only of sufficient volume to lubricate the bearings adequately. This is seldom if ever accomplished. When the cup is full the oil flows freely, dropping off as the level falls. If at the low levels the bearings are receiving sufficient oil, then when the rate of flow increases with the higher levels the conclusion must follow that oil is being wasted. It is almost safe to make the statement that nine

out of every ten wick feeders supply more oil than is necessary, that is, assuming high grade oils are used. The possibility of changing the number of strands in a wick and of determining the proper length wick to give the correct flow and avoid fluctuation is of great importance. It has been determined that the lower end of the wick adjusted at a distance of about 2 inches below the lowest oil level will increase the uniformity of flow at all levels. Greater wick lengths than this do not alter the effect appreciably, while if the wick is much shorter, there will be an excessive variation of oil flow between fillings.

The study of wick feeders can be carried to the point of taking out the strands of the wick, one at a time, watching the effect on the bearing temperatures and, when the bearing begins to overheat, replace one strand of wick for safety. Once the proper balance is obtained, the flow will remain practically the same if the lubricant used is of the same quality.

There is no given set of rules applicable to the lubrication of ship machinery or a specific oil or grease that is standard for any and all services. There are fundamental principles of good lubricating practice, however, and suggested applications of various oils especially adapted to particular types of machinery in the following outline of the lubrication problem that will suggest possible economy measures to the operator and to the engineer.

The lubrication of the thrust bearing is extremely important, since this bearing takes the entire driving force that propels the ship. There are three general types of thrust bearings; first the plain type, in which the thrust rings or collars fixed on the shaft are fitted in recesses in the lower and upper bearing sections; second, the horse-shoe type, in which the thrust rings bear against collars of horse-shoe shape, which can be adjusted separately; the third, bearings of the Kingsbury, Michell and

Gibbs types, which are specially designed to assure automatically the even distribution of pressure on the bearing surface. The plain type is used in some small installations, the horse-shoe type is very common in reciprocating engine installations of all sizes, while the special types of the third group are common in modern steam turbine practice and are meeting with increasing acceptance for reciprocating steam and Diesel installations.

For lubrication of thrust bearings the common methods of application are oil bath and wick feed oilers. Plain and horse-shoe thrust bearings generally have an oil bath. The revolving collars pick up oil from the bath and force its circulation through grooves, from which it is distributed. For starting, oil is delivered to the bearing surfaces by wick feeds, which are generally provided, assuring that the bearing will not be scored before the oil from the bath is properly distributed. The special types of thrust bearings mentioned are generally lubricated by bath, sometimes supplemented by forced circulation of the oil. The oil reservoirs of large thrust bearings are often provided with water cooling coils for maintaining moderate oil temperatures.

Where plain or horse-shoe thrust bearings are oiled by bath or wick feed, a rich lubricant with heavy body should be employed, correctly compounded so that it will form a lubricating emulsion with any water that may be present. These requirements usually call for the same oil as should be used for the main engine bearings and guides. Occasionally, when the duty of the thrust is especially severe, a still heavier and more strongly compounded oil will relieve the difficulties encountered.

It is specially important that the oil used on the plain and horse-shoe type of thrust be of a high grade, well adapted to this particular service, because an unsuitable oil will not attain a satisfactory emulsion. Under continued operation this emulsion will tend to become heavier and heavier, until the oil ways become so clogged that the only lubrication remain-

ing is that furnished by the wick feed oilers. Overheating and loss of the bearing is the probable result. This condition of the oil necessitates cleaning out the bearing and renewing the oil. The correct oil for this purpose will form a fairly thick emulsion, still retaining its flowing and lubricating qualities during long periods of service.

The special types of thrust bearings mentioned are nearly always constructed with a tight casing which keeps water out. The use of a large oil reservoir for the bath also facilitates the separation of any water that may accidentally enter the bearing. The bearings may be well lubricated by the use of a pure mineral oil of lighter body than that for the other types of bearings. For turbine installations this is generally the same oil as that on the main turbine bearings. The use of a high quality oil for this purpose assures long useful service.

OIL REQUIREMENTS FOR TUNNEL BEARINGS

The general type of tunnel bearing installed in connection with the average reciprocating steam engine is of the plain spring type. Tunnel bearings are generally lubricated with marine engine oil or a tunnel bearing grease or both. If oil is used it is ordinarily applied by means of wick feed, the top half of the bearing cap being built with an oil box cast in it. A good oil can be reclaimed and used several times.

Where grease is used in the tunnel bearings it is comparatively hard in composition, having a very high melting point. Grease lubrication may keep the bearing surfaces in good condition, but always results in greater frictional power loss than with the use of a suitable oil. For this reason bearings built for grease lubrication are often fitted with wick feed trays, made to fit the grease recess, so that oil can be applied.

TURBINE LUBRICANT REQUIREMENTS

The high surface speed and small shaft clearances in direct connected turbines require a light bodied oil that will circulate readily. It must also be of the proper quality to maintain an oil film with minimum fluid friction on the turbine and thrust bearings.

Direct connected turbine drive vessels are not economical, as the turbine must be run at too slow a speed and the propeller at too high a rate for efficiency. Turbo-electric drive ships are not in extensive use so the discussion of the lubricating problem will be confined to geared drive vessels.

Reduction gears may be either single or double. A usual ratio of speeds in double reduction gears is 3,500 revolutions per minute on the high speed shaft, 500 revolutions on the intermediate and 100 revolutions on the low speed shaft. Herringbone gears are in general used for reduction although straight tooth spur gearing has been used to some extent.

The oil that would normally be selected for the turbine bearings alone is sometimes of too light a body for the reduction gears, where the tooth pressures range from 500 to 750 pounds per linear inch. The duty of the oil in the gears is not only to maintain a lubricating film, but also to form a cushion that will prevent shock and wear on the tooth surfaces. Since it is generally impractical to use separate oils on bearings and gears, a reasonable compromise is made by using an oil throughout, which is of sufficient body to satisfy the gears requirements. The oils that have been found most satisfactory for this service have a viscosity between 250 and 300 seconds Saybolt at 100 degrees F. On slow running gears which normally have higher tooth pressures, and on gears poorly cut or badly worn, heavier oils are sometimes found advantageous.

Oils as heavy as the foregoing result in unnecessary fluid friction in cool bearings. In many geared turbines, the bearings are so located that they are kept warm due to the heat from the turbine. The effect of this is to reduce the operating body of the oil, creating a condition such that the heavier oil selected for gear lubrication also satisfied the

bearing requirements without causing excessive fluid friction.

It must never be assumed merely because an unknown oil has a viscosity within a prescribed specification range, that it will give satisfactory performance in the turbine. For long continued satisfactory service there is no place where it is more important than in the steam turbine to employ a high grade oil that has been carefully developed for the exact performance intended. A safe choice cannot be made on the basis of any set of specifications. No laboratory tests are equal to the service results accumulated from the records of many machines of the class, covering long periods of time.

SYSTEMS OF LUBRICATION EMPLOYED

The most important factor in arriving at good lubrication of turbine units is the provision of a thoroughly reliable system both for the turbine and the gears. Pressure and gravity circulation systems are most extensively employed for oiling. In the gravity circulation system, the lubricant is carried to a gravity tank located high enough to obtain about 15 pounds' pressure which is necessary to supply the parts to be lubricated. The oil is then permitted to flow through the bearings and gears to the sump. The oil from the sump is returned by means of a pump through strainers, a separator and a cooler, to the gravity tank, thus providing a constant circulation of the lubricant. A gravity circulation system in a steam turbine usually contains about 1,800 gallons of oil, while a pressure circulation system contains somewhat less oil because of the elimination of the gravity tank. Because of the fact that the oil is constantly in motion in these systems a special kind of oil and a special treatment of that oil must be provided.

The pressure system of lubrication is cheaper than the gravity since less equipment is required. In operating this system, the lubricating oil pumps draw the oil from the sump or drain tank or purifying system and apply it to the unit under pressure, the oil draining back to the drain tank where it is again picked up by the pumps and again applied to the unit. The circulation of oil through this system is therefore continuous.

The proper quantity and quality of lubricant must be maintained in the turbine system and for the auxiliaries. Some pressure installations are fitted to operate with too low a capacity of oil. On the average ship the system should be of ample size to handle from 800 to 1,000 gallons in continuous circulation. Certain units at present are operating under as low as 400 gallons in the system and this provides so rapid a circulation of oil that after it has come in contact with the heated bearings it does not have time to settle and cool and therefore is subject to rapid deterioration. To function properly, the pressure system should pump oil to the bearings in excess of that required, a relief valve or other means being provided to drain the excess oil back to the sump tank.

In turbine driven vessels the oil that is used for the main drive may also be used for most of the other service on board. The average replacement of new oil should not exceed 15 gallons per day in ordinary cargo ships.

On ships equipped with refrigerator spaces three types of oil in general are required—that for the main turbine drive and auxiliaries, ice machine and possibly cylinder oil. As the lubricant used in the steam turbine system must be a straight mineral oil it is not considered wise to carry a supply of oil on board that will emulsify, not even in cases where horse-shoe thrust bearings are used because of the possibility that this oil might be accidentally placed in the turbine system where it would cause trouble.

An excellent method of controlling the treatment of oil is to place a sample from the low point in the turbine system in a long small clear glass bottle for observation. The sample is allowed to settle for four hours and each engineer is thus able to maintain an accurate check on the condition of the oil and any changes that might have occurred in the system.

If water is getting into the system, it may thus be discovered immediately and the cause of the water determined and the evil eliminated or given the necessary attention.

The oil used must separate easily and quickly from water and other impurities picked up in the system. Water in the system with the oil tends to form an objectionable mixture that clogs the screens and forms a slime on the cooling coils, thus reducing the efficiency of the cooler as a heat-extracting device. In extreme cases, the free circulation of the oil is interfered with by the slime so formed, and lubrication is affected.

SYSTEMS OF PURIFYING THE OIL BY FILTRATION

Three methods of filtering the oil in the lubrication system may be resorted to. In the periodic batch filtration system, the entire charge of oil in the system is drained at definite intervals when, in the judgment of the operator, it is deemed advisable to recondition the oil. After all the oil has been drained from the system and the parts thoroughly cleaned, new oil is introduced. To filter used oil it should be heated to a temperature of from 160 to 180 degrees F. which hastens the water separation and improves the purity of the oil when subjected to filtration. This method requires two or three days for completion and so is not generally applicable.

In the continuous filtration system all the oil is passed through a combination settling and filtering tank. The quality of the oil is effectively maintained in this way while the large volume used in the system provides a relatively long time for settling out impurities. The filter should be cleaned of impurities regularly.

The continuous by-pass system of filtration provides for a small quantity of oil to be constantly withdrawn from the system through a small filter and returned to the sump. This oil is taken from the lowest point in the sump tank or from the bottom of the gravity tank where solid impurities or water will naturally be found. If impurities are present, idle periods may be utilized to recondition all of the oil. With this method oil can be in continuous service for several months without appreciable deterioration.

Centrifugal oil separators may also be used in conjunction with any system of filtration. They provide a satisfactory method of purifying oil at sea and a positive system for purification when in port. In even a moderate sea the gravity settling system is rendered inefficient by the motion of the ship, while under favorable conditions in port the pressure of gravity is not sufficient to effect complete purification. With the centrifugal system it is possible to purify the oil continuously or by the batch method as desired.

The arrangement commonly used places the purifier on the same level as the turbines. When it is operated continuously with such a system the course of the oil is roughly as follows: Coming from the turbine bearings it flows into the oil drain tank and is pumped by either of two steam pumps through the oil cooler into one or the other of the two overhead tanks shown at the right of the diagram. From a point slightly above the connection of this tank the oil flows back through the strainer to the turbine. A stream of oil is constantly drawn from the bottom of the tank and passed into the purifier where water, dirt and other sludge are centrifuged out. The purified oil is delivered into the drain tank and goes back into the overflow tank along with that coming from the turbine bearings.

FACTORS DETERMINING SERVICE OF LUBRICATING OILS

When starting up a new turbine for the first time, there are always present in the system impurities of many kinds such as core sand, scale, chips, fibers, etc. It is good practice after the trial run to remove the entire supply and subject it to filtration or centrifugal purification.

It is well to keep a check on the records of oil consumption in order to eliminate any irregularities caused by leakage of water in or oil out. Evaporation losses are relatively small in a turbine system, particularly as the oil temperatures, reduced by the cooling, are much below the temperature of vaporization.

Oil foaming in the system may be due to air leaks. Where foaming persists it may be prevented by the use of vents in the oil tanks and by operating at higher oil temperatures which has a tendency to cause the bubbles to break up quickly. Water finds its way into the circulation system in spite of every precaution and the careful construction of packing glands. Constant supervision must be maintained to keep down the amount of water present. Water and a highly refined oil emulsion will readily separate when allowed to rest. When an inferior grade of oil is used, however, in which finely divided insoluble substances are present, an emulsion of a permanent nature is formed. To prevent this, pure mineral oil of high grade and special manufacture must be used. The elimination of emulsion and sludge from a circulation system is necessary to maintain the proper efficiency of the oil, as these impurities will precipitate in the oil reservoir, in the strainer or filter, on the cooling coils or in the bearing housing, all seriously affecting the reliable operation of the turbine.

The lubrication of Diesel engines and auxiliary machinery will be discussed in a later issue of this magazine.

The Leviathan—The New Flagship of the American Merchant Marine

WHEN our next issue reaches its readers, the reconstructed *Leviathan*, now the largest ship in the world, and perhaps the fastest liner afloat, will be ready to sail on her maiden voyage from New York to Cherbourg and Southampton as the flagship of the American merchant marine. In the hands of the Newport News Shipbuilding and Dry Dock Company, and with the aid of a host of subcontractors, this vessel has been completely reconditioned so that she represents the last word in safety, luxury and convenience for travelers at sea. In the July issue of *Marine Engineering and Shipping Age*, will be published a complete profusely illustrated description of the passenger accommodations of this magnificent contender for the blue ribbon of the seas. Details of the structural changes and the reconditioning of the propelling and auxiliary machinery of the vessel were published in our November, 1922, issue.

New Furnace Front for Dahl Oil Burner

Greater Accessibility and Better Air Regulation Secured by Swinging Feature of New Front

A NEW type of swinging furnace front has recently been developed by Bethlehem Shipbuilding Corporation, Ltd., for use in installations of the Dahl mechanical oil burning systems, which are manufactured at their Moore plant, Elizabeth, N. J. This front is suitable for use with

Fig. 1.—Swinging Type Furnace Front for Natural or Forced Draft Installations, Shown in Operating Position

either natural or forced draft, or with a combination of both. The swinging feature of the new front, in addition to retaining all of the desirable features of the non-swinging type, possesses special advantages in regard to accessibility and air regulation that the other type does not.

The air register is a substantial cylindrical casting having nine air vanes cast integral with two flanges of rugged design, the front one of which acts as support for the swinging pot, the rear one being bolted to the boiler furnace front.

A cylindrical regulating pot air check governs the amount of air admitted by opening and closing the air inlet. The air regulating pot is controlled by means of a hand-operated rack and pinion.

The cylindrical air regulating pot and air regulation pot head are separate castings, clamped together by two dogs. The air controlling gear and cone adjusting gear are the same in both swinging and non-swinging types.

The swinging front permits of air regulation when working under natural draft, forced draft, or combined natural and forced draft, and under all conditions of operating it may be swung open to permit of easy access to the furnace interior without dismantling any part of the boiler front. When working on natural draft installation, the cylindrical air regulating pot and air regulation pot head are one casting. Regulation of the air is accomplished by adjusting the air regulation pot. In this case the air is admitted through the register vanes which are open to the boiler room.

Withdrawing the pot and pot head along a cylindrical bracket placed in the center of the crossbar, by means of the rack and pinion, and swinging them open permits of inspection and easy access to the interior of the furnaces without dismantling the boiler front or fuel oil piping.

When operating under forced draft, the register is enclosed by the air duct, and adjustment for air control is by means of the rack and pinion which operates the air regulating pot and pot head. Closing the air regulating pot over the register vanes cuts off the forced draft and permits of swinging the air regulating pot head, burner and regu-

lating cone clear of the register for inspection without destroying draft conditions on other furnaces being supplied from the same duct. The swinging clear of the pot head and door frame permits of inspection and access to the furnaces without dismantling the furnace front or fuel oil piping. To do this, the two dogs are thrown clear of air regulating pot, the latch bolt is disconnected and the air regulation pot head is withdrawn from the air regulating pot. While these various movements are taking place, the air regulating pot seals the register, thus preventing leakage of air during examination of burner and regulating cone.

Fig. 2.—Swinging Type Furnace Front in Open Position with Air Regulating Pot in Closed Position, Showing Easy Access to Furnace Interior

When working under natural draft on a combined forced and natural draft installation, the air regulation pot remains in the closed position shown in Fig. 1, shutting off the forced draft through the air duct. The two dogs are disconnected and the air regulating pot head is withdrawn for the admission of air, by means of the hand operated rack and pinion, thus giving a definite air control.

If for any reason it is found desirable to admit a still greater quantity of air, the two doors in the air regulating pot head can be opened. Access to the interior of the furnace is obtained as described above.

A number of installations of this design of furnace front have already been made with excellent results, demonstrating ease of operation, flexibility of control of air regulation, complete atomization and high efficiency resulting in a practically smokeless flame and the highest attainable percentage of CO_2 at the stack.

Arc Welding Applied to Shipbuilding

BEGINNING in the July issue of *Marine Engineering and Shipping Age*, Mr. E. W. Ewertz, general manager of the Moore Plant, of the Bethlehem Shipbuilding Company, Ltd., will present a complete summary of the application of welding to ship construction, a comparison of welding with riveting, a description of the arc welded ships already in existence and their performance, a review of repairs to the German liners and the results of tests in England and the United States to demonstrate the adequacy of welding as applied to ship construction, a description of the several designs of welded ships, a comparison of the advantages of welding versus riveting and finally a bibliography of the subject.

A Direct Course Is A Direct Saving

By Robert B. Lea*

All the carefully worked out engine room and shore economies are seriously affected if the captain of a vessel is not able to direct his ship over the shortest ocean course between ports.

GREAT advances have been made in the last century in the art of ship propulsion, but there have been no corresponding contributions to aid the captain and commander of a vessel. In fact the advances in the engine room in several respects have increased the captain's burden of responsibility, for the greater speed which modern machinery has given to vessels has gone beyond the power of the feeble magnetic compass to respond as quickly as it should. Secondly, the metal and machinery which have replaced the old time wooden hull and sails have introduced grave magnetic disturbances, the compensation for which robs the magnetic compass of much of its already feeble directive force. For this reason the gyro has long been indispensable on war vessels and over one thousand ships of the world's navies are using the gyro compass. Here the compass is used not only for navigation but to direct the very accurate gunfire control.

Directly after the war the gyro compass was first tried in the merchant service and its contributions found to be

so unique and substantial that already 36 of the world's leading fleets have vessels navigated by gyro.

ADVANTAGES OF GYRO NAVIGATION

The economies and advantages of gyro navigation can be briefly stated as follows:

First, the gyro compass makes possible true north navigation. For the small gyro wheel in the master compass ever maintains its axis with a definite relation to the earth's axis, thus affording freedom from those ever-present worries—variation and deviation. The elimination of these two factors does much to reduce the mental hazards of the navigator. And every aid is worth while which will simplify the responsibilities of the master of a modern vessel representing the large capital investment that it does.

Secondly, since the gyro compass is so many times more powerful than the magnetic it responds to the slightest yaw of a vessel, thus enabling the quartermasters to steer a much straighter course. An idea of the difference in directive force is given in the treatise as published a few years ago by Commander T. A. Lyons of the U. S. Navy. The Sperry

*Manager, Marine Department, the Sperry Gyroscope Company, Brooklyn, N. Y.

Steering by Magnetic Compass

Steering by Gyro Compass

Mk VI, or merchant type compass, has 137 times the directive force of the U. S. Navy standard $7\frac{1}{2}$ -inch liquid compass used in the tests.

The accompanying illustration shows comparative records made by a tanker. It will be noted that the vessel was yawing on an average of about 5 degrees when steered by magnetic and this was immediately reduced to an average of $1\frac{1}{2}$ degrees when the quartermaster was allowed to steer by gyro.

A ship appears to be ever anxious to yaw off her desired course *without really changing her direction of motion*. Unless she is prevented from doing this by the prompt action of helm, she cuts a much wider swath through the water. This, of course, means power loss. One large transatlantic liner reports a saving of $1\frac{1}{2}$ to 2 percent of fuel consumption due to straighter steering.

Another economy results from this straighter steering which is brought about by a more prompt application of the helm

Steering by Gyro, Captain Examining Course Record in Background

than is the case with the sluggish magnetic: namely, a smaller amount of rudder is used. This affords an appreciable reduction in the number of propeller revolutions required to drive a vessel a given distance and can be readily realized by those who have observed the retarding effect of drag from a rudder at wide angles. One coastal liner finds that she now requires on an average of 5,000 fewer revolutions on a run of about 900 miles.

DEAD RECKONING MADE ACCURATE

The third contribution of the gyro compass to economy is the ability of a captain to more accurately navigate by dead reckoning, especially when the weather is such that check sights cannot be taken. This is perhaps best expressed in the report of a captain of a large intercoastal freighter:

"I wish to state without any hesitation that never before have I seen a vessel make the courses or the landfalls that I have seen made this trip. When I expected to make a light at such and such a time and bearing such and such a degree, true to form there it would be right on the dot. If I figured

Steering Repeater, Reveals a Yaw of One-Sixth of a Degree

to pass five miles off of that light when abeam, five miles it surely would be.

"I read somewhere that dead reckoning with a gyroscope was raised from an indefinite quantity to a mathematical accuracy and I want to corroborate that statement. Since leaving New York I have steered between 15 and 20 courses and upon recapitulating find that the course made good in

Master Gyro Compass. This Instrument Controls Steering Repeater, Bearing Repeater and Course Recorder

all but two instances has always been the exact course steered by gyro. This, to me, is a phenomenal surprise."

Or perhaps the following taken from a foreign technical paper:

"Not the least interesting of the many up-to-date appliances shown to me on board was the Sperry gyro-compass, which, by giving a more precise line of route unaffected by magnetic deviation, saves the ship about 80 pounds sterling a trip."

Another advantage of special interest to the management on shore is that the gyro compass makes possible the use of a machine that records every heading or change of heading of a vessel over a long period of time.

COURSE RECORDER ELIMINATES INEFFICIENCY

The latest "course recorder" affords a continuous record for 30 days on a single strip of paper. Several companies have already made use of these records in court where the visual evidence was of great value in proving the position and heading of a vessel at the time of accident. The presence of this instrument in the wheelhouse has been found to serve as a continuous moral stimulant to the quartermasters' alertness. What is more important, it enables a captain to eliminate inefficient wheelmen with their costly steering, for it is found that some men seem unable to acquire the knack of holding a vessel closely to a required course.

The chart reproduced at the beginning of this article

shows this striking difference in quartermasters while the vessel was proceeding under the same weather conditions.

"METAL MIKE"

To carry these savings further, the Gyro Pilot, or automatic steering device, has been developed and is about to be introduced. This mechanism has greater alertness than a quartermaster in giving a vessel the proper helm. And neither does "Metal Mike," as this iron quartermaster has been dubbed by captains, get tired after a two-hour watch, or become drowsy around 4 a. m. On several ships thus equipped the wheel has not been touched by human hand for days at a time.

The fifth type of saving is effected when pilots, through their greater confidence in the gyro compass, particularly when making sharp channel turns, bring their vessels up through the fog or haze to the dock when otherwise they might feel inclined to drop anchor. Many instances of this are reported, such as a recent case where a captain was able to land his passengers in the late afternoon while another vessel approaching the entrance buoys at the same time, but not equipped with a gyro compass, felt obliged to drop anchor until morning. This gain in time for unloading mails, passengers and cargo may well represent large sums.

It is thus interesting to realize that the principle of the street vender's toy has been put to work and contributes to the more economical and safer navigation of merchant vessels.

Oil Engines Designed for Large Liners

Seven Thousand Brake Horsepower Double-Acting Motors and 3,000 Brake Horsepower Single-Acting Plant

By Our Special London Correspondent

DURING the past two or three years, interest in oil engine construction has chiefly been centered around motors of moderate power and, generally speaking, up to about 2,000 brake horsepower. It is probable that this represents the widest field of application for marine internal combustion machinery but, in view of the demand that has arisen for motor passenger liners, considerable attention has lately been devoted to the production of engines of high power.

Undoubtedly the most noteworthy example is the new Burmeister and Wain double-acting four-cycle type. As previously mentioned, two motors of this design of about 7,000 brake horsepower are to be installed in a passenger liner for the Swedish-American Line, and it is now possible to give some details and illustrations of the 1,100 brake horsepower single-cylinder experimental engine which the builders have constructed, before proceeding with the manufacture of six-cylinder sets of practically the same design.

HIGH PISTON SPEED ADOPTED

The engine develops its power at 125 revolutions per minute and has a bore and stroke of about 33 and 59 inches, respectively. It will be noted that this gives the exceedingly high piston speed of between 1,200 and 1,250 feet per minute, whereas in most of the marine Diesel engines that have previously been built, the figure has seldom exceeded 800 or at most 850 feet per minute. With their wide experience, Messrs. Burmeister and Wain would not have adopted such a piston speed, if they were not confident of its suitability, but it is generally considered that piston ring wear is a function of speed, and it will therefore be interesting to learn whether any difficulties are encountered in actual

service. It should be added, however, that equally high piston speeds have been employed in submarine engines for some years past, so that the development is not entirely novel.

The cylinder cover at the top of the engine is more or less normal, with exhaust, inlet, air starting and fuel valves operated from long push rods from the camshaft in accordance with Burmeister and Wain single-acting practice. In the bottom cylinder cover, however, only three valves are located: The exhaust, inlet and starting air valves. There are two fuel valves, but these are arranged horizontally in a distance piece between the cylinder cover and cylinder. Through these, fuel is injected tangentially at points almost diametrically opposite, on account of the interference of the piston rod. It will be realized that the power developed at the bottom of the piston is not equal to that on the top, owing to the fact that the piston rod passes through the combustion chamber, and that the net effective cylinder diameter is correspondingly reduced.

Although the engines in the liner will be fitted for the ordinary system of fuel injection by compressed air, they will not drive their own air compressors. Separate Diesel driven units of 600 brake horsepower will be installed in the engine room for this purpose and in this way, a higher shaft horsepower will be developed for a given cylinder dimension than would otherwise have been possible. It is estimated that the consumption on each of the 7,000 brake horsepower motors will be in the neighborhood of 30 tons daily.

SINGLE-ACTING ENGINES FOR NEW GERMAN LINER

The highest powered Diesel engines built in Europe for installation in a ship have just been completed and have

One of Two 3,000 Brake Horsepower Sulzer Engines to Be Installed in the German Liner *Fulda*

been installed in the new 9,500-ton transatlantic passenger liner which the North German Lloyd is building for its service between Bremen and New York. These motors, of which an illustration is given, are of the Sulzer type and are normal two-cycle single-acting sets developing their power at 100 revolutions per minute. They have six cylinders, 680 millimeters bore with a stroke of 1,100 millimeters and it will be observed that although two injection air compressors are driven off the crankshaft, there is no scavenging pump. This is in accordance with the latest Sulzer practice. In the ship, the scavenging air will be provided by two rotary blowers, each driven by a 300 brake horsepower motor, running at about 2,750 to 3,000 revolutions per minute. The total power absorbed for supplying scavenging air to two propelling engines of 6,000 brake horsepower will, it is estimated, be under 250 brake horsepower.

In these engines, the scavenging air, at a pressure of 1.4 pounds per square inch is admitted as usual through two series of ports, the upper row giving a super-charge after the exhaust ports are closed. The starting air and fuel valves are arranged in one housing, so that only one hole has to be provided in the cylinder cover, and the valve gear, operated from an overhead camshaft, is comparatively simple. As the illustration shows, the control gear for the engine is arranged at the level of the top grating, a system that is now almost universally adopted in Sulzer engines. There is, however, a good deal of auxiliary machinery at the engine room floor level, and in case of necessity, the main engines must be capable of control when the engineer is below. A lever is therefore arranged which will enable the attendant to stop either of the propelling engines, if it is so desired, when he is at the bottom of the engine room.

The engine drives its own lubricating oil pumps and also an additional pump, supplying oil at a pressure of about

250 to 300 pounds per square inch to the crosshead bearing. This arises from the fact that the pressure on this bearing is not relieved during every revolution, as is the case with a four-cycle single-acting motor. The main cooling water pumps are separately driven, one being provided for the cylinder jackets, in which sea water is used, and another for piston cooling, fresh water being employed in this instance.

The trials on these engines appear to have given remarkably good results. The fuel consumption for the engine alone works out at about 0.395 pound per brake horsepower, while, if the power needed for driving the electrical auxiliaries be added, the total consumption varies between 0.41 and 0.42 pound per brake horsepower. The passenger liner in which the two engines will be installed, named the *Fulda*, is being built by the Weser Company at Bremen, and will have a cabin accommodation for about 870 people, the majority of the cabins being arranged for third class passengers.

Another passenger liner of 12,000 tons gross is being constructed in Germany by Blohm and Voss for the Hamburg South American Line and in this case also, twin screw machinery of between 6,000 and 7,000 brake horsepower is to be installed. The engines are, however, being constructed by Blohm and Voss, and will be of the normal four-cycle construction as developed by this firm in conjunction with the M. A. N. of Nürnberg.

ORIGIN OF FIRES ON BOARD SHIPS.—According to a recent notice given to shipowners and shipbuilders by the British Board of Trade, which analyzed 241 fires occurring during one year on British ships, 70 percent of the fires occurred in bunker spaces, 12.1 percent were due to oil fires including launches, and 17.9 percent were due to miscellaneous and other causes, including superstructure and engine room fires.

Tuning Up the Engine and Boiler Room—II

Written on Board the George Washington as a Good
Example of What Can Be Done with Existing Ships

By William L. Bunker*

THE air pumps are of various makes and types, the latest and best known being the vertical type pump fitted with a large brass plunger and a properly sized bronze cylinder. It is fitted with foot, bucket, and head valves. There is also the independent air pump, either of the duplex or simplex type, fitted in the same manner and the Edwards type which consists of a solid brass plunger with only one set of valves and is usually called the displacement type of air pump.

Air pumps should be examined periodically, either monthly or not exceeding 60 days, care being taken to see that packing in the plunger, which is usually flax and sometimes of brass rings, is in good condition. The valves which of recent years are of a close grain bronze, should be examined to see if they are cracked or warped, and that valve seats, gaskets, etc., are in good condition and not loose or unduly worn.

From the air pump the feed water is discharged into a hot well or very often a filter box. The latter is a tank with efficient compartments, one or more of which are filled with absorbent material to soak up any grease that is in the feed water. It then passes through to the feed pumps on its way to the boiler.

Feed water filters are usually constructed with several compartments or in duplicates so that one can be shut off while the other is being cleaned and the water passed through the other while this process is going on. Aloofa sponges, cocoa mats, excelsior and other material is used in these feed water filters and in plants where, on account of superheated steam or for other reasons, lubricating oil is fed inside the cylinders this absorbent material should be changed at least twice a day and in many instances every watch of four hours. When a longer time is allowed to elapse the object of a feed water filter is lost and the grease passes to the boilers.

FEED PUMPS

The feed pumps are usually in duplicate and large enough so that half of the installation can handle the feed water at full speed. Therefore, the overhauling of these pumps can be done at sea without a shutdown which would be necessary should all pumps let go at one time.

The feed pump, which is generally a vertical direct connected type, consists of a steam cylinder and a water cylinder. For purposes of economy, this pump is usually of the simplex type operated by an automatically controlled piston valve admitting steam to both ends of the cylinder. Care must be taken to keep this automatic steam valve, usually called the chest piston, and the walls of the cylinder parallel, otherwise this valve will stick, causing a stoppage of the pump. The valve gear attached to the crosshead of the pump and operating this valve must also be watched closely to see that undue wear does not take place.

The steam piston should be examined monthly to see that the rings are tight and the cylinder should also be examined to see that the walls are parallel and in good condition. The water end of the pump needs constant attention and should be overhauled at periods not exceeding one month or when the vessel stops at terminal port. The packing in the plungers is of various types; good results are obtained by the use of a long white-metal plunger with adequate water grooves,

providing the plunger is made long enough to reduce wear of the cylinder. Narrow rings of white metal should not be fitted in a plunger as many breakdowns of feed pumps have been so caused. Where the stroke of the pump does not permit a long, solid, white-metal plunger to be used, various packings of a fibrous nature can be fitted, the most common of which is called woodite or ebonite. This material gives good results for a feed water temperature up to and including 220 degrees Fahrenheit.

The valves in the water end of feed pumps should be set to a very restricted lift due to the pounding action which takes place when valves are allowed to lift too high. This hammering action wears the seat, breaks the valve and puts the pump out of commission in a short time.

FEED WATER HEATERS

After leaving the feed pump the water passes through the feed water heater on its way to the boiler. Although there are many kinds of feed water heaters there are two principal types, the open type and the closed type. The open or Weir type is where the exhaust steam from other auxiliaries is met and condensed by a spray formed by flowing feed water passing through jets or nozzles. The water absorbs the heat in the exhaust steam and falls by gravity to the feed pump. The open heaters must be located at a considerable height above the feed pump or excessive slamming will take place caused by the vacuum created by the piston of the feed pump liberating vapor from the hot water. The water should flow in solid mass to fill the space left by the retreating plunger. Unless great height is used for open heaters it is impossible to get the feed water above 200 degrees Fahrenheit.

The other type called the closed heater consists of a series of coils through which the feed water passes. The coils are contained in a tank-like structure into which the exhaust steam enters. When this steam comes in contact with the cooler coils heat is liberated from the steam and the condensation is drained back into the hot well. By the use of greater surfaces and higher back pressure the feed water can be brought to a very high temperature. From 220 degrees to 230 degrees Fahrenheit is very often the temperature of the feed water as it passes through the checks of the boilers. However, the bad feature of this is the back pressure and engineers should not allow this pressure to get higher than is necessary to conform with the best economical results. This can be done only by careful measurements and calibrations of the feed water. Engineers should remember that a saving of approximately 11 degrees in feed water means 1 percent saving in fuel.

After the feed water leaves the heater, pipes are very often left exposed to the atmosphere and lose by radiation the heat gained in the feed water heater. This should be corrected by heavy insulation on the feed water line.

MISCELLANEOUS PUMPS

The pumps and pumping arrangements on board modern ships are of many kinds indeed and they vary from the heavy duty ballast pump to the small service pump used to send chilled water through passenger spaces for the convenience of those on board.

The ballast pump, which is usually connected by suction

*Superintending engineer, United States Lines.

pipes to all inner bottoms, bilge lines, etc., discharges overboard; however, it sometimes has an outlet to the main condensers so that it can be used in emergency cases to keep the ship moving at a reduced speed should any mishap occur to the circulating unit.

The items set down as governing the feed pump do not hold good in the case of the ballast pump which is always of an entirely different type, functioning under a low pressure system. The steam ends are of the usual type, but the pumps are generally of the duplex type and have the valve mechanism of one cylinder operated by the crosshead of the adjoining unit which is set at right angles. The valve gear then becomes of the positive type and less care is required to keep it in operating condition. Care should be taken, however, to

Reciprocating Engine Driving Centrifugal Circulating Pump

keep the link motion well fitted and in good condition so that the pump will not act in a jerky and faulty manner.

The water-end plungers are usually packed with a low grade material such as flax or other fibrous packing and the valves which are much larger than those of the feed type are usually made of rubber or some fibrous material. These pumps should undergo a periodical overhauling at intervals not exceeding 30 days.

SANITARY PUMP

The sanitary pump is usually of the same type as the ballast pump, namely, low pressure because the volume is used more for sanitary purposes than for pressure. The suction of this pump is always connected to the sea and discharges only into the sanitary system usually through a tank fitted on the superstructure allowing the head of water to flow through the accommodations on board the vessel. This pump should never have any other connections on account of obstruction to the fine mechanisms of flushometer valves, etc.

Where engineers find the suction of this pump connected to bilges, they should change this by blanking off this inlet,

thus using only clean water for the sanitary system. On some vessels that ply more or less in polluted waters, it is deemed essential to have filter tanks on the discharge side of the pump to remove all refuse from inlet water so that the delicate valves that are commonly fitted to flushometers and shower bath outlets in passenger accommodations will not be choked up. A pressure gage should be fitted to the filter so that the engineer can tell when filtering material needs changing.

FIRE PUMP

Fire pumps are usually of a heavier pattern than either ballast or sanitary pumps, for it is required that they maintain a pressure of at least 100 pounds per square inch for fire use on the upper decks of vessels. In order to obtain this head of water on the upper deck it often requires considerable more pressure than this at the pump. It is best practice to have this pump connected to the bilges, since it is often used for washing decks as well as for fire use. Dirty and greasy water from bilges pumped onto the decks of passenger ships sometimes leads to blows between the deck and engineering departments.

BILGE PUMP

Generally one or more pumps of adequate size are fitted for the use of bilges only. These pumps should be connected to other lines to be used in case of emergency. They are usually a combination type. All fittings on the water end of these pumps should be of composition metal to avoid corrosion.

FRESH WATER PUMPS

These pumps are of the usual low pressure type. Since they are used for fresh water only and as little corrosion takes place, they require the least amount of care.

EVAPORATORS

The law requires that an adequate evaporator and distilling plant be fitted to all vessels. They are especially essential on passenger ships. Evaporators of the coil type having a capacity of between 20 to 30 tons of water per day are usually installed aboard ship.

The manner in which evaporators function is simple in nature. Steam is taken in through coils which are partially submerged in sea water which causes the heated sea water to vaporize. This water vapor is taken either to a condenser to be used for feed water or passed into a distiller, which is nothing more than a small condenser where the distilled water is discharged through an aerator and through filter filled with animal charcoal and then discharged into the ship's drinking tanks.

The efficiency of an evaporator depends a great deal upon the amount of scale that is allowed to collect on the coils or evaporating surfaces. Many engineers use a system of filling the coils with cold water when they are hot in order to loosen this scale. This is done by blowing the evaporator entirely dry and refilling with cold water, thereby causing a sudden contraction of the heating coils which loosens the scale and allows it to break off and fall to the bottom.

This is a very bad practice and should be avoided because sudden contraction of the coils soon causes leaks in connections and fatigues the metal. The correct way to clean an evaporator is by the good old-fashioned system, that is, by opening the evaporator and removing the scale either by tapping the coils with a wooden mallet or by removing with a scraper of approved design. Safety valves should be fitted on evaporators allowing about 15 pounds per square inch shell pressure and care should be taken to keep these relief valves in good working order.

Little care is needed with the distillers except to keep the tubes tight so that salt water cannot mingle with the drinking water produced by the evaporator. Careful attention should be taken to see that the animal charcoal is kept

od condition and renewed at intervals of about six months, according to the amount of use the apparatus is put to.

GENERATING PLANT

Direct current of 110 volts on the two-wire system is the st practice aboard ships. The steam driven generators are her turbines direct connected, geared turbines or reciprocating engines. With either type the most important matter is keep the governor in good condition. Due to the uneven erating loads which are always placed upon electrical ants, it is necessary to have a positive and sensitive governor. In recent years, several engineers have been killed pile shutting down a turbine generator where the governor d become inoperative. Therefore, where high speed ared turbines are used, the engineer should see that he s a distant operating mechanism for shutting off the steam case of an accident.

Little need be said about the reciprocating engine since is so well known and is usually reliable and fairly efficient. The only objection that can be raised to a reciprocating engine is a tendency to pump lubricating oil back through e feed water unless care is taken in keeping piston rods, and, etc., tight and in using the proper grade of oil in e dynamo.

REFRIGERATORS

The refrigerating plants fitted to freight ships are usually the small ammonia type of from one to three ton capacities, according to the size of the vessel and the trade ute involved.

With passenger vessels, however, the refrigerating plant s become a very important item in the ship's equipment. e machines are generally either the ammonia type or the rbonic acid gas type using the indirect cooling system ich is circulated to absorb the heat in the brine system. his brine system is pumped in turn through coils placed in e refrigerating compartment which is ordinarily overhead. sorbing the heat in this compartment it is returned to e tank to be again chilled by the circulation and expansion e carbonic acid gas or ammonia. Carbonic acid gas is eferable to ammonia on account of the danger of escaping s through a ruptured pipe or fitting. If the escaping gas ammonia, it is liable to drive the engineers from the comrtment and also, where refrigerating plants are located tside of the engine room, to cause considerable inconvenience to passengers.

Little can be said relative to the economy of either synn, since both are highly efficient when used in a properly signed and constructed machine.

Two of Vessel's Equipment of Six Dynamos, Each Consisting of Compound Engine Driving Compound Wound Generator

Main Switchboard

With the ammonia plant it is necessary to maintain a much smaller clearance than with the CO₂ machine. In both cases the engineer must keep a vigilant and constant watch over all glands and connections to avoid the loss of gas. The grade of lubricating oil is also a great factor in the successful operation of either type of machine. The very highest grade of oil guaranteed by well known oil companies is none too good for the use of this apparatus. On each gas condenser a relief valve should be fitted and this valve proven to be in operating condition every week. Many condenser boxes are ruptured by the failure of this valve to work.

Sometimes the discharge valve from the condenser is closed by mistake or not opened when starting the machine and very often the discharge on the ship's side is stopped up by the vessel lying against a fender at the pier. The discharge is usually near the water line so that the overflow will not get into cargo lighters when the ship is light; this brings it close to or below water line when the vessel is loaded.

STEERING APPARATUS

Steering apparatus on board ship is very important and too much care cannot be taken to keep this machinery in the best possible condition. The steam tiller operated from the bridge by a hydraulic telemotor system is the usual type and nothing has been produced up to date which can compare to this apparatus. Many kinds of electrical systems and hydraulic gears have been installed only to be discarded and replaced by the steam apparatus.

In large ships where rudders are subject to heavy shocks from breaking seas, some means should be provided to absorb these blows either by some steam tiller apparatus such as the Brown steam tiller or by the use of heavy spiral springs and buffer rods as fitted by many well known shipbuilders.

The steam to the steering gear should be reduced in pressure through a reducing valve of some well known type, care being taken to have a by-pass fitted to pass the steam around this reducing valve in case it becomes inoperative.

On all vessels of a modern up-to-date steamship company the steering apparatus is tested out before the departure of the vessel in the presence of the chief officer, chief engineer and a representative of the shore staff. A form which states the apparatus is in good working condition is then filled out and signed by all concerned.

The greatest difference between the steering apparatus and other machinery on board the ship is the construction of the admission valve or, as it is sometimes called, the differential or follow-up valve. This valve keeps steam passing into the

engine until the operating wheel governing the telemotor is stopped, the apparatus then stays in that position until reversed or changed by the operating wheel in the pilot house.

The telemotor and differential gear should be thoroughly overhauled and inspected at every terminal port; the steering engine itself overhauled at intervals not to exceed 60 days.

ANCHOR WINDLASS

Windlasses are used to raise the ground tackle and when fitted with a gypsy head they are also used to warp the vessel to and from piers, etc. The engine for driving this apparatus is of the usual reciprocating steam engine type which operates a wildcat gear used for raising and lowering the anchors. The wildcats are fitted to the driving shaft and are so constructed that the links of the anchor cable chain engage with sprockets which deliver the chain into the chain locker. The wildcats are fitted loose on the shaft and are so constructed that the releasing gear can be used either to clutch the gear to the engine for lifting, or, by disengaging it, for lowering the anchor. The wildcat is fitted with a brake of heavy construction called the compressor-band which is operated to check the chain and hold the same when vessel is anchored.

On larger vessels riding clamps are fitted to the chain so that the strain can be taken off the wildcats when the vessel is riding at anchor. These riding clamps are usually operated by a right and left hand thread and when exposed to the weather should be well greased to avoid deterioration by rust.

While the windlass usually comes under the care of the carpenter, it will save the steamship company much money for repairs and also annoyance to all concerned, if the engineers take an interest and see that the windlass is well oiled, greased and kept repaired, remembering that a stitch in time saves nine.

WINCHES

When in operation in port the engine department should have one man detailed to see that all bearings on winches are oiled every half hour and that the piston rods and valve stems are swabbed well with cylinder oil at least once an hour.

It is found that main engine oil which is pumped out of crank pits and filtered often works well on winches, especially where some of the rape seed content is allowed to remain. This rape seed together with the water which works into the bearings forms a lather. Considerable saving can be made by using a heavy sticky grease for slushing the gears and this should be done several times during the day when winches are in operation. Heavy oil or grease should be applied to all rods and bright parts of winches when the vessel leaves port to keep sea and rain water from rusting or corroding the metal.

Heavy guards should be well fitted over gears and moving parts to avoid accidents to workmen and also to keep wire ropes and falls from getting between the gears, causing a breakdown. Steam pipes to winches should be covered and lagged with some of the new coatings such as thorkote which is impervious to water and makes a good insulation. Steam cylinders should not be lagged especially where a pocket is formed by the valve chest and cylinder coming together unless water-proof cement, as mentioned before, is used. The sheet iron lagging, when fitted, always leaks and the average insulation becomes soaked with water and acts more as a condenser than as an insulation, and also increases the corroding effect on the metal.

The latest style of fitting winches has proved very satisfactory, which is to place a winch several feet above the deck and when at sea the machine is covered with a heavy canvas which keeps off the rain and sea water. This system pays well by prolonging the life of the winch.

Kearfott Engineering Company Takes Over American Agency for Lockwood and Carlisle Piston Packing Rings and Springs

SO many American ships are fitted with Lockwood and Carlisle's patent piston packing rings and springs that the agency for the United States has been taken over by the Kearfott Engineering Company, of 95 Liberty Street, New York.

These springs, which are standard on most British lines are now used in increasing numbers. The spring is simple and efficient and is designed to have two distinct actions, one to press the packing rings outwards against the walls of the cylinder, and the other to make steam-tight joints on the piston and junk ring faces. The friction is reduced to a minimum so as just to ensure steam-tightness, and the side or vertical compression forms a steam-tight joint on piston

Piston Packing Ring

flanges. With these double-action springs thorough steam tightness is secured, it is claimed, with the least possible amount of friction. The packings are simply and easily adjusted when required.

For superheated steam the high pressure rings and springs have two flat uncut restraining rings, one on the top and one on the bottom, the whole forming a safeguard against excessive wear of superheated steam of high pressure.

A modification of the rings is made by Lockwood and Carlisle for piston valves. These rings and springs prevent the steam gaining access to the spring space at the back of the rings by means of a double-acting spring. This spring gives a strong vertical pressure which keeps the faces tight while the outward action, which is quite independent of the vertical, can be reduced to a minimum.

Rings and springs are made for every class of auxiliary steam engine, viz., steering, dynamo, pumps, refrigerating winches, etc.

Protective Coatings for Shipbuilding Purposes— Bituminous Compositions

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their use that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

WHERE a protective coating of the nature of a paint is desired but something more durably efficient than paint is needed, bituminous coatings are usually employed. Steel surfaces of coal bunkers, of double bottom water tanks under or near boilers, of refrigerated spaces and, in some cases, of the bilges are subject to excessive corrosion and are good subjects for the application of bituminous coatings.

These coatings may have an asphalt or a coal tar base; there are also somewhat similar coatings made from mineral rubber or Elaterite.

Bituminous coatings as deck coverings have been dealt with in the writer's article on that subject in the issues of his magazine for March and April, 1922. Bituminous coatings on ships' bottoms are of particular interest in connection with concrete ship construction and have been dealt with in the writer's article on "Cement and Concrete" in the June, 1922, issue of this magazine.

The coating consists of one or more coats of a solution applied directly to the clean, dry metal surface, upon which there is usually a final coat of enamel. The thickness of the enamel coat depends upon the severity of the service. The composition of the solution and enamel must be such that the covering will be firmly adherent, sufficiently elastic not to crack or break up, and of a softening point that will not allow it to flow or be indented by traffic at temperatures met with in the various places where it is used on shipboard. Specifications for these coatings adopted by the United States Shipping Board Emergency Fleet Corporation are a good guide to what is necessary to meet these requirements, and they are here copied.

SHIPPING BOARD SPECIFICATIONS FOR BITUMINOUS COATINGS

Bituminous Solution and Enamel:

Bituminous solution and enamel will be acceptable when made on an asphalt or a coal tar base.

Bituminous Solution (Asphalt):

This shall consist of an asphalt or combination of asphalts of same characteristics as that used in the asphalt enamel except that no mineral matter shall be added. It shall be thinned to satisfactory covering, brushing and working properties with mineral spirits. It shall dry at least to a tacky state within twenty-four hours so as to provide satisfactory bond between metal and enamel coating. This bituminous solution shall not flash below 40 degrees C. by the open cup method.

Bituminous Enamel (Asphalt):

(a) This shall be composed of a high grade water-rejecting asphalt or combination of asphalts containing not over 20 percent of Portland cement and added lime compound. (See later—H. H. T.) It shall show the following physical and chemical characteristics:

(b) Penetration at 25 degrees C. not more than 15 nor less than 5. (Standard A. S. T. M. method.)

Ductility at 25 degrees C. not less than 1 centimeter. (Method A. S. T. M. Committee Reports 1915, page 349.)

Loss at 163 degrees C. for 5 hours on 20 gram sample not more than 0.5 percent.

(c) Melting point (ring and ball method) not less than 80 degrees C. (176 degrees F.). Total ash not more than 30 percent.

(d) When the solution and enamel are applied in the manner of their use to a test metal panel, the coatings must be unaffected when maintained at a temperature of 65 degrees C. in a vertical position for 2 hours to the extent of not becoming tacky, running or sagging from the vertical surface.

(e) When solution and enamel are applied in the manner of their use to a steel panel at least 18 inches square and not less than $\frac{3}{8}$ -inch thick, the coating shall stand the blow of a steel ball weighing 700 grams dropped from a height of 180 centimeters without flaking from the plate except beneath the point of impact and no radial cracks shall develop longer than 5 centimeters from center of point of impact. During this test the steel plate shall be supported in a horizontal position and support shall be placed beneath the point of impact. This test shall be made at a temperature between 25 degrees and 30 degrees C.

4. Bituminous Solution (Coal Tar):

This shall consist of a coal tar pitch of the same characteristics as used in the coal tar enamel, except that no mineral matter shall be added. It shall be thinned to satisfactory covering, working and brushing properties with a coal tar distillate. It shall dry to at least a tacky state within twenty-four hours so as to provide satisfactory bond between metal and enamel coating. This bituminous solution shall not flash below 40 degrees C. by the open cup method.

5. Bituminous Enamel (Coal Tar):

(a) This shall be made from coal tar pitch free from water, gas or oil tar pitch and be well mixed with finely powdered mineral filler not in excess of 20 percent. It shall show the following characteristics:

Loss at 163 degrees C. for 5 hours on 20 gram sample not more than 3 percent.

Melting point (cube method) in water or glycerine bath not less than 80 degrees C. (176 degrees F.).

Total ash not to exceed 20 percent.

Free carbon not less than 15 percent nor more than 30 percent.

(b) When solution and enamel are applied in the manner of their use to a test metal panel, the coating must be unaffected when maintained at a temperature of 65 degrees C. in a vertical position for 2 hours, to the extent of not being tacky, running or sagging from the metal surface.

(c) When solution and enamel are applied in the manner of their use to a steel panel at least 18 inches square and not less than $\frac{3}{8}$ inch thick, the coating shall stand the blow of a steel ball weighing 750 grams dropped from a height of 180 centimeters without flaking from the plate except beneath the point of impact, and no radial cracks shall develop longer than 5 centimeters from center of point of impact. During this test the steel plate shall be supported in a horizontal position and support shall be placed beneath the point of impact. This test shall be made at a temperature between 25 degrees and 30 degrees C.

In 3 (a) of the above specifications there is the statement that the asphalt enamel shall contain not over 20 percent of Portland cement and added lime compound. The United States Bureau of Standards has stated regarding this that according to its experience any finely ground inert mineral filler, such as finely ground clay, is satisfactory for the preparation of bituminous enamels for the inside of the hulls of steel vessels; but that slaked lime should not be used, as its effect upon bituminous materials is questionable and serious defects probably due to it have resulted in similar mix-

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

tures produced for other purposes. It will be noted from the melting point that the enamel has to be applied hot.

As with other compounds dealt with in these articles, the test of actual service is important, and there are a number of proprietary makes of bituminous coatings which have proved satisfactory. The Bureau of Construction and Repair of the Navy Department has a dozen or more of them on its approved list.

A compound made from Elaterite or mineral rubber named Elaterite 45-A has given good results as a protective coating for iron and steel. It makes a strong bond with the steel and is applied cold. In the ease of its application it has a decided advantage over bituminous enamels. It has received classification society approval as a substitute for bituminous solution and enamel. The manufacturers definitely state, however, that for comparative results when used for this purpose not less than four coats should be applied and preferably five coats.

Some other coatings that are applied cold with heavy dauber brushes, compounds of asphaltum, oils and fillers, have given good results; but they cannot be expected to equal bituminous enamels. When using them no priming coat is required, it is unnecessary to remove oils and greases and even a little dirt on the surfaces is not a serious matter.

Navy Department requirements as to the use and method of application of bituminous compositions as given in the 1918 edition of the General Instructions for Painting and Cementing Vessels of the United States Navy are in the main as follows:

The following spaces on all vessels (except over galvanized plating of destroyers or on vessels of special light construction) shall be coated with an approved bituminous solution and cement or enamel: Trimming tanks, drainage tanks, reserve feed-water tanks, ship's fresh-water tanks, gravity tanks, sand lockers, top of inner bottom in engine and boiler rooms, dynamo and dynamo condenser rooms, also the inner surface (including stiffeners, etc.) of bulkheads surrounding the engine and boiler rooms to the height of the floor plates, and all foundations, etc., in these spaces to the same height; connecting passages between machinery spaces, shaft alleys, all closed spaces in foundations, girders and pockets that are inaccessible after completion and at junction of an inclined deck and ship's side; also the inner surface of bulkheads surrounding the dynamo condenser rooms to a height of about 2 feet above the inner bottom and foundation in these spaces to the same height; also interior of battery-charging station. Coal bunkers and chain lockers shall be coated with two coats of bituminous solution of the approved list contained in the Bureau files. Special attention shall be given to the thorough protection of portions of the machinery spaces which may become difficult of access upon completion. The foregoing shall not substitute bituminous compositions for spaces required hereinafter to be coated or filled with asphalt cement (formula No. 60).

Fresh-water tanks coated with bituminous solution and enamel shall be thoroughly washed out three times before the delivery of the vessel to the Government. In each case they shall be filled with fresh water, allowed to stand not less than six days before being emptied, and the tanks washed. The last washing shall take place not more than thirty days before the delivery of the vessel to the Government.

APPLICATION: Metal shall be free from paint and thoroughly clean, and, at times of application of any protective coating, surfaces shall be thoroughly dry. One coat of the bituminous solution shall be applied and be well spread out with a brush. This preliminary coating, necessary with either the enamel or the cement, shall be followed, after drying or at least becoming tacky, by a coat of cement or enamel applied hot; the cement being suitable for flat horizontal surface is poured on hot and spread rapidly with a brush or by some equally efficient means to a minimum thickness of one-fourth inch. The enamel which is applied hot is suitable for overhead and vertical or inclined surfaces where the cement can not be used, and shall be applied to a minimum thickness of one-sixteenth inch. Bulkhead bounding angles, boiler foundations, and other metal work projecting through the cement shall have the bituminous cement poured along the lower edge in order to completely coat the angle.

Artificial ventilation shall be furnished while any bituminous coating is being applied.

The asphalt cement referred to in the foregoing excerpts is the composition given under that heading in the writer's article on "Cement and Concrete" in the July, 1922, issue.

It will be noted that double-bottom tank tops in the engine and boiler rooms are among the items required to be coated with bituminous solution and enamel. This procedure as far as the boiler room is concerned is seriously objected to by some of the large operators, marine engineers and others, as far as oil burning vessels are concerned. In some cases Portland cement or Roman cement is substituted (see the July, 1922, issue of this magazine). The claims are made that, if fuel oil on the fire room tank top catches fire, the bituminous coating on the steel work also catches fire and tends to spread the flames; that the bituminous coating absorbs spilled oil and gives off vapors for a long time afterwards, thus adding to the resultant discomfort and increasing the danger on this account as well as on account of becoming saturated with oil; and that the fuel oil disintegrates the bituminous coating and causes it to flow. The last claim is also made for lubricating oil acting upon a bituminous tank top coating in the engine room. Regardless of what merit there may be in these arguments, it is questionable, if bituminous coatings are usually necessary for the protection of boiler room tank tops where oil is used as fuel. It may be of interest in this connection to state that oil tanker specifications submitted by shipbuilders as a basis for contract specifications to the United States Shipping Board Emergency Fleet Corporation, in accordance with pre-war construction and with the customary oil fired boilers, called for bituminous coatings on the engine and boiler room tank tops with but one exception. In this exception these coatings were required on the engine room tank top but not on the boiler room tank top.

The author considers that the following specifications typify good practice in the use of bituminous coatings:

1. Engine room tank top, one coat of solution and one coat of enamel $\frac{1}{4}$ -inch thick.
2. Boiler room tank top, of coal burning vessels, one coat of solution and one coat of enamel $\frac{1}{4}$ -inch thick.
3. Engine room bilges to 6 inches above the working platform, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.
4. Boiler room bilges to 6 inches above the working platform, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.
5. Tank top in shaft tunnel, one coat of solution and one coat of enamel $\frac{1}{4}$ -inch thick.
6. Inside surfaces of shaft tunnel and recesses at forward and after ends to 6 inches above the working platform, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.
7. Inside surfaces of hold and 'tween deck coal bunkers where oil is not to be carried, two coats of solution on the under side of the decks, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick on interior surfaces, and one coat of solution and one coat of enamel $\frac{1}{4}$ -inch thick on shell surfaces.
8. Interior of chain locker, two coats of solution on the under side of any deck or flat, and one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick on all other surfaces except the bottom. One coat of solution and asphalt cement on the bottom.
9. Interior of refrigerating room, two coats of solution on the under side of the deck, and one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick on all other surfaces.
10. Interior surfaces of double bottom tanks in way of engine and boiler rooms, where oil is not to be carried, from the aft engine room bulkhead to about 6 feet forward of the forward boiler room bulkhead, two coats of solution on the under side of the tank top, and one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick on all other surfaces.
11. Interior of double bottom pump wells and cofferdams, two coats of solution on the under side of the tank top, and one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick on all other surfaces.
12. Floors and keelsons of single bottom vessels in way of boilers, where not filled in with cement, one coat of solution and one coat of enamel $\frac{1}{4}$ -inch thick.
13. Bulkheads in the engine and boiler rooms to one foot above the working platform, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.
14. Steel decks under composition deck covering, two coats of solution.
15. Bilges in cargo holds to the height of tank side brackets, one coat of solution and one coat of enamel $\frac{1}{4}$ -inch thick.
16. Engine, boiler and auxiliary machinery seatings to the height of the working platforms, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.
17. Surfaces of shell, floor plates, etc., in shaft spectacles of twin

screw ships, where not filled in with cement, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.

Additional items for which the expense of bituminous coatings is sometimes warranted are:

18. All interior surfaces of fore and after peak tanks, where not filled in with cement and where oil is not to be carried, two coats of solution on the under side of any deck or flat, one coat of solution and one coat of enamel $\frac{1}{4}$ -inch thick on the shell for a height of about 5 feet, and one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick on all other surfaces.

19. Boiler room tank tops of oil burning vessels, two coats of solution.

20. All bulkheads for the distance of 18 inches up from the tank top, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.

21. Deck in way of the ice machine, and ice machine seatings, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.

22. Winch seatings and deck in way of same, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.

23. Steering engine seating and deck in way of same, one coat of solution and one coat of enamel $\frac{1}{8}$ -inch thick.

It will be noted that double bottom tank tops in holds are not referred to in the foregoing requirements. It is customary to have wood ceiling on these tank tops, and a very effective and inexpensive coating is obtained by a thick brush coat of liquid tar, using old brooms, and dusting this

with sufficient Portland cement powder to get a white surface. The tar absorbs the cement and the black color comes to the surface in a short time, but the coating does not flow.

It might be asked why no enamel is recommended for the under side of the tank top in items 10 and 11, and the under side of other flat surfaces. This is because in such locations two coats of solution, properly applied, should be sufficient, and because the hot enamel is difficult to apply on overhead surfaces and particularly difficult in confined spaces like a double bottom.

The value of carrying the bituminous coatings in the double bottom several frame spaces forward of the boiler room bulkhead was brought home to the writer as a result of examinations of double bottom tanks made in connection with damage from grounding. In several cases the carefully protected tanks under the boilers were found to be in good condition while the steel work in the after two or three frame spaces of the tank next forward of the boiler room, upon which the usual Portland cement wash coating had been applied, was found to be badly corroded. The balance of the tank in every case was in good condition, being apparently beyond the range of destructive action due to the heat from the boilers.

British Shipping and Shipbuilding Developments

Indications Against Revival in Shipbuilding—Motorship May Be Exception—Obsolete Tonnage a Menace—Scrapping Plan Needed

By W. H. Wendon

JUDGING from the order books of the principal shipbuilders, the shipowners of the United Kingdom, after their recent little flutter in regard to the placing of contracts for new vessels, would appear to have decided almost unanimously that there must be a breathing space before further contracts for tonnage are awarded. What little demand there was for cargo steamers has, in fact, practically ceased. So far as passenger vessels are concerned, shipowners maintain that, inasmuch as building costs are, in their opinion, too high, it is idle to discuss new contracts, especially as the existing tonnage is capable of coping with the present traffic.

On the other hand, there are numerous inquiries for cargo vessels fitted with Diesels, and some of the proposals which are being made have features which are not unattractive. A Diesel-engined cargo boat, carrying 9,000 to 10,000 tons deadweight, could be built, it is computed, for about £14 per ton, smaller ships necessarily costing more per ton, and on this basis, for vessels of the type indicated, it is felt in usually well-informed circles that such boats appear to be a possibility of the not distant future which owners will be unable safely to ignore.

The factors which are inducing owners to refrain from entering into fresh tonnage commitments are worthy of closer study. Take, as a case in point, the attitude of Messrs. Alfred Holt & Company, the managers of the Blue Funnel Line. Messrs. Holt have now had delivered to them the *Dardanus*, a vessel of 10,000 tons deadweight and 15 knots speed, and, for the time being, the last Blue Funnel liner under construction. Messrs. Holt confess, with not uncommendable courage, that like all, or nearly all, other shipping people, they made the radical mistake of thinking that trade would be more prosperous and more progressive after the war. The result is that they entered into commitments which exceeded their power to fulfill conveniently, but having fulfilled these contracts they find themselves unable, as I have

indicated, to give a further order, at all events for the present.

EXPECTED ABOLISHMENT OF EXCESS PROFITS TAX

The fact is, as all who have followed the subject will agree, that many British shipowners considered that, at the beginning of 1920, when freight rates were at their peak, the excess profits duty would be abolished, and that such profits would accrue as would permit of expensive new or second-hand tonnage being paid for without placing the shipowners in a dangerous financial position. But the increase of the tax from 40 percent to 60 percent dashed to the ground the hopes of the shipowners; the slump ensued, and so it happens that many owners, even at this distant time, are still hard pressed to carry out the new tonnage commitments into which they so light-heartedly entered.

The experience of Messrs. Holt & Company with the *Dardanus* is typical of what has taken place with so many other vessels. The building cost was admittedly high, but due to circumstances over which the builders had no control. The steel was purchased at a very high figure, and labor costs at the time the contract was placed were heavy. Work on the vessel had to be suspended, and during the suspension the expenses of keeping the ship in order ran on. Appreciable reductions in shipbuilding costs have been effected, but the view is unanimously held that they will remain high above the pre-war level. Unskilled men in many cases receive the same rates as—in some cases higher rates than—skilled workers, a condition which obviously should not be.

GOVERNMENT REGULATIONS INCREASE BURDEN

Shipbuilders, too, are fettered by government regulations which, in years gone by, were non-existent. Delays and increases of cost are caused by the obligation to adapt plans of ships to Board of Trade rules, and especially to comply with the requirements of the International Convention. In

at least one respect, therefore, shipbuilders are not to blame if costs are too high. Tramp steamers can, it is said, be built at 50 percent over pre-war prices, but one well-known shipbuilder gives it as his considered opinion that passenger vessels could not be constructed at such figures.

The trying time through which the shipping and allied industries are struggling to emerge is exemplified in the North Country view that, as regards new orders for ships to be built or the sale of ships that were building, the past year has been by far the worst period that any living shipbuilder can remember. Practically no new orders were given by shipowners until the closing weeks of the year; on most of those partly built work was suspended, and when ships had to be sold the prices obtainable were only about one-third of what would have been readily secured in 1919-20.

For the remainder of the current year, the Newcastle Chamber of Commerce considers that it is doubtful whether any shipbuilders or marine engineers can avoid showing a considerable loss unless they draw on their reserves. If activity in shipbuilding is to be maintained, the chamber holds that either prices must be increased or the costs of building must be further reduced.

THE MENACE OF OBSOLETE TONNAGE

The question: To scrap or not to scrap? continues to exercise the minds of all connected with shipping, and not least those of the shipowners themselves. There is as yet, however, no sign of a fixed policy, or anything approaching thereto. It is generally agreed that the mass of obsolete and inefficient tonnage which, in its present condition, can never be operated at a profit, will continue to menace the market.

One of the best known British shipowners stated quite recently that, in his opinion, the sooner all non-commercial American ships and old British vessels are broken up, the better it will be for the shipping trade of all nations. But, however good this famous shipowner's intentions may be, it is out of the question to avoid the personal issue, as may be gaged from the fact that, while this shipowner advocates "scrapping," one of the companies under his control has just disposed of a steamer, not for breaking up, but for operating, and to foreign buyers at that.

SCRAPPING AGREEMENT NEEDED

When it is analyzed, however, there is nothing unnatural about the transaction, or the many others which might be cited. There is no possible chance of a scrapping program succeeding while it is confined to individual action. If the shipowner referred to had sold the vessel for breaking up, he would have realized probably about half the sum that was actually netted, and while, in the former case, he would have been acting in the best interests of shipowners generally, in that the vessel would be taken off the world's markets, his own company would have suffered to no small extent. Obviously shipowners cannot, as individuals, face their shareholders with the intimation that vessels owned by the company have been sold for breaking up at reduced prices in order that the international market might benefit.

The question of scrapping obsolete or semi-obsolete merchant ships, while not "as old as the hills," is certainly not a new one. The topic has come up for discussion whenever a depression, great or small, has appeared on the shipping horizon. But it has never been found possible to devise such an arrangement that an owner who, in the common cause, has disposed of his vessel to shipbreakers will be compensated for his loss out of a common fund.

HERR BALLIN'S PLAN

The most authoritative and oft-quoted view on this important subject is that of the late and great German shipowner, Herr Albert Ballin, whose tragic demise some few

years ago is still fresh in memory. Herr Ballin's "warning," as it was termed at the time, was penned in the closing days of 1911. The scheme suggested by Herr Ballin, to make provision during a time of prosperity for dealing with the inevitable future time of adversity, instead of waiting until the actual pressure of those harder times became burdensome, was that the owners of the large passenger lines should get rid of passenger vessels that had outlived their day, from the travelers' point of view, and should, in the public interest, cease to be in service.

A British shipowner, the late Mr. Welsford, advocated a more ambitious scheme for the temporary withdrawal from service of surplus tonnage when the world's carrying requirements fell below the capabilities of the available tonnage provided, so that, at least, barely living freights might be maintained instead of steamers being run at almost universal loss.

INSURANCE COMPENSATION

Herr Ballin believed that it might be possible, through some scheme of insurance, mutual or otherwise, to provide that steamers reaching a certain age—he suggested 20 years—and that had paid a very small insurance premium on their original cost regularly during their lifetime—which premiums would have accumulated at compound interest—should, on attaining the agreed age, be considered as having performed their life-work and be put on the scrap-heap, the owners receiving a price—say, 20 or 25 percent of their original cost—in consideration of the ships being broken up.

If at an earlier date they had met with misfortune, or had been sold to foreign owners, Herr Ballin planned that the premiums paid on them would, of course, be forfeited, and, therefore, the insurance company, or society, could accept lower premiums than would otherwise be necessary. He suggested that some of the leading British insurance companies, possessed of large capital, should quote what they would undertake it for.

Herr Ballin agreed that all these projects were more or less crude, and would require consideration and careful working out. His sole purpose was to call attention to the bad times which would inevitably follow the then good times, and to suggest that it would be wisdom on the part of shipowners, both British and German, to make arrangements which would mollify the hardships that were bound to come. Much has happened since his suggestions were outlined and the Great War has ruled out Germany as a main factor in any scheme which might be planned, but, among all the great maritime powers, there is apparently none which can evolve a really workable program.

SAFETY OF LIFE AT SEA

The recommendations just announced by the Merchant Shipping Advisory Committee with regard to life-saving appliances, training and organization on foreign-going passenger steamships will, it is hoped, help to solve some of the many knotty problems bound up with the general question of safety of life at sea. The committee is representative of all the principal shipping interests—shipowners, officers and men, pilots, shipbuilders, naval architects and underwriters—and has as its chairman a leading shipping light—Sir Norman Hill, the secretary of the Liverpool Steamship Owners' Association.

In addition to the committee men referred to, there are two members of Parliament, whose aim on the committee is to study the welfare of the traveling public. It is noteworthy that the report which the committee has issued, through the Board of Trade, is unanimous, and the recommendations contained in the report may be summarized thus:

1. Boats for all on board should be carried as far as is possible without encumbering the decks and impeding the prompt handling of lifeboats or the marshalling of the passengers. The committee observe that this is practicable in the great majority of existing foreign-going passenger steamships.

2. Where lifeboats for all cannot be provided without encumbering the decks and hampering the use of the boats already on board, the deficiency of accommodation for all on board should be met by means of light, buoyant apparatus.
3. In any case, however, over and above accommodation for all on board, light, buoyant apparatus should be provided for 25 percent of the persons on board for use in emergencies when it is not possible to launch all the boats.
4. Motor lifeboats fitted with wireless telegraphy should be carried in certain cases.
5. Illumination of the lifeboats in launching and immediately after being launched should be provided.
6. Boat drill stations to be established at the principal ports.

EXCEPTION TO HAGUE RULES RECOMMENDED

Progress has been made in the matter of the Carriage of Goods by Sea Bill, the measure planned to give force to the well-known "Hague Rules," but there are still important points outstanding. One of these points is in regard to coal, coke and patent fuel cargoes, which the British Coal Exporters' Federation consider should be excluded from the scope of the bill. The contention of the federation is that, while they appreciate the benefit which the rules would be to those traders who ship parcels of goods by liners under a

bill of lading alone, coal exporters for 25 years, together with the shipowners and coal importers, have negotiated agreed charter-parties and suitable bills of lading, and, when amendments were necessary, a conference of the parties was duly convened.

The members of the federation feel keenly that the bill would put the coal exporters in an unsatisfactory position as compared with that under the system of voluntary agreements. So strong, in fact, is their conviction on this point that they have put their case before the Lord Chancellor, who has promised to give the whole matter his careful consideration.

The rules incorporated in the bill, however, represent an agreement reached between the shipowners, manufacturers and merchants, not only in Great Britain, but abroad, and, in fulfillment of their promise to hold by the rules as they now stand, shipowners readily support the bill. They realize that in many respects material amendments might be desired in the bill and in the rules, but they recognize that any alteration in the latter would jeopardize the prospects of securing international uniformity, and that the bill incorporating them gives substantial effect to the bargain made.

Recent Developments in Marine Insurance

Flat Rates—Fuel Oil Hazards—Constructive Total Loss—Adjustments at Destination—Under-Deck Stowage—Right of Abandonment

By "Bordereaux"

SHIPOWNERS show poor judgment when they insure their old and new vessels at a flat rate. In a recent illustration of this method the owner had one old vessel and several modern ones. He asked and received a flat rate for all. In a short time after, the old steamer was lost, prior to the policy becoming operative. The result was that the new contract for insurance became effective on the new steamers only, with the age of the old steamer influencing the entire coverage. The better method is to insure each vessel on its own basis; the new ships have the advantage of a better rate and the cost of the coverage as a whole works out more scientifically and generally to the advantage of the owner.

Oil As Fuel

BY now the shipping trade is pretty well sold on the use of oil as a fuel. This is evidenced in the rapidity with which coal is being displaced and the Diesel engine coming into its own. But from the standpoint of the underwriter doubt still exists as to the comparative hazards surrounding coal and oil. He has become familiar with bunker fires, the shifting of bunker coal, cargo damage from coal dust, etc., and he has protected himself against their consequences by the use of controlling clauses. He recognizes the advantages of oil, but he views with pardonable anxiety the next set of problems involved.

Tank types for carrying the oil reserve are bothering him. They have to be not only oil-tight at the beginning of the voyage, but they must remain so en route under stress of all kinds of weather. It was at first found convenient to use the double bottom tank, and likewise the fore and after peak tank. Experience soon showed that the double bottom tanks when partially emptied on a voyage had a serious effect upon the stability of the vessel, and also that it was unwise to permit the oil to flow from one side of the vessel to the other. Accordingly, bulkheads were recommended which would so

divide the tanks as to prevent this development. It was also found that in transferring fuel from the peak tanks great care had to be exercised in making the transfer lines tight, as serious damage frequently resulted from leaky or broken transfer pipes. The number of cargo damage cases, through failure to make the tanks tight, has been legion. In one instance, for example, the manhole cover was left off the fore peak tank, and the oil flowed from the tank into hold No. 1 damaging a large quantity of flour.

These sources of danger, however, are insignificant compared with that of the great outstanding hazard of fire. An oil fire cannot be handled along the same lines as an ordinary fire. Oil tanks have frequently exploded because of fire and the inadequate methods employed to combat it. Careful data are being kept of disasters resulting from the use of oil fuel, not only by the syndicates but by individual underwriters as well. Froth, steam, and numerous fire extinguishing apparatus are provided by vessel owners, and inventive minds are constantly at work to supply new and improved safeguards. It remains, however, a question of considerable doubt as to whether cargoes which absorb odors easily can be safely carried by oil burners, with the smell of oil permeating the holds.

Constructive Total Loss

SOME interesting views by English judicial authorities were recently brought out in a case of alleged constructive total loss. In this instance the policy covered a cargo of coal en route from New York to Sevastapol, and the question of the liability of the underwriters was raised. In the course of the voyage a change of destination was made, without having been initialled by the underwriters; the coal being discharged and sold at Constantinople. A claim for constructive total loss was based on the fact that the cargo never reached its destination, and the adventure was not completed. It was held by the court that when

goods have to be discharged, reconditioned, reloaded and carried on to the port of destination, and it is discovered that the cost of these operations exceeds the probable value of the goods at the port of destination, there is a constructive total loss. Also that there is a constructive total loss when it is clear that as a matter of business it is quite impracticable to send the cargo on to its ultimate destination. The judgment of the presiding Justice was that the adventure in this instance was put to an end by the heating of the cargo in the hold of the vessel as she lay at Constantinople, and that it was impracticable from a business point of view, and commercially impossible, to send the coal forward; and that the loss was the result of the fire. Judgment was given for the plaintiffs.

Average Adjustments at Destination

OUR readers will recall the discussion conducted in this department in recent issues with respect to the advantages and disadvantages of having general average adjustments made at ports of destination, as was the usual practice prior to the World War. This important question was taken up and thoroughly gone over at the recent meeting of the International Chamber of Commerce at Rome. At that time the American delegates presented the attitude of their underwriting countrymen, which was in opposition to any change in the present method, the argument being that too generally there is apt to be a lack of competent adjusters and of established laws and usages as respects general average at ports of destination. However, the final attitude of the International Chamber was reflected in a resolution, given below, favoring a return to the pre-war practice. M. de Roussiers, representing French shipowners' interests, suggested that parties should be allowed to provide such other mode of adjustment as they thought fit, and that there should be an admission of freedom of contract to vary the rule. This position was opposed by the British delegates, and the French suggestion was tabled. The text of the resolution, as finally adopted, was as follows:

"The settled practice as regards general average, with certain recognized exceptions, is that unless the bills of lading or charter-parties stipulate for York-Antwerp Rules, 1890, or otherwise, it will be adjusted in accordance with the laws of the port of destination, if the voyage is completed, and, if not, then laws of the place where ship and cargo part company.

"With regard to the place of adjustment, it has been the general practice, with certain exceptions, referred to later, that if at the port of destination there are established laws and usages as well as competent adjusters the adjustment is prepared there.

"In certain trades, however, when a voyage extends to ports in various countries, and/or when the insurance is placed and guarantees taken at the home port, it has been found in practice desirable to have the adjustment prepared there.

"The effort in recent years to extend this practice by stipulating in bills of lading or charter-parties for adjustment at specially named places, such as London or New York, irrespective of trade or destination, is undesirable and frequently involves delay and extra cost in adjustment.

"The Congress, therefore, strongly recommend that the practice existing before the war in these matters should be maintained."

Right of Abandonment

COURT action has been recently had in a very unusual case involving the clause refusing the right of abandonment. This clause is exceedingly rare, and in the event of a serious casualty being sustained it is bound to lead to dispute. In this particular instance the American Merchant Marine Company was sued by the Liberty Sand and Gravel Company, Inc., in connection with insurance of a dredger in New York and Long Island Sound. The dredger sank, and the underwriters contended that this resulted from unseaworthiness, which was excluded from the policy. The latter contract contained a clause reading: "The insured shall not have the right to abandon the ves-

sel." Abandonment was, however, tendered and refused. Thereafter, it appears, the insurance company raised the wreck and placed her in drydock, and had her surveyed with the idea of repairing her. But they were charged with the duty of returning her without making any repairs or otherwise meeting liability. It would seem as though the plan at this point was to hold the underwriters to a total loss. The dredger was then bored with holes which were plugged, and she was removed from the drydock, floated to the place where she had been raised, the plugs taken out, and the vessel sunk.

The judge of the lower court held that this extraordinary action amounted to acceptance of abandonment on the part of the underwriters, and the court of appeals sustained the decision. The latter court, however, decided against the dredger company on the point of sue and labor, holding that the insurance company was not liable to contribute to the expenses incurred by the assured. The dispute evidently grew out of the "right to abandonment" clause.

Under-Deck Stowage

IN a recent decision, Judge John H. Partridge, of the Federal Court at San Francisco, has added the weight of his opinion to the familiar judgment that goods must be stowed under deck if a bill of lading is to be classed as "clean." The steamer *Fairhaven*, which stranded off Mazatlan, December 6, 1921, carried a number of cases of potatoes and tomatoes, consigned to San Francisco merchants. They were stowed under the bridge, despite the issuance of a clean bill of lading. The York-Antwerp Rules and various legal authorities were cited in support of the contention that a clean bill of lading requires stowage under decks. As the goods in this instance had been carried on deck and subsequently jettisoned the court held that general average contributions were not allowable.

The Falling Mark

GERMAN marine underwriters are inserting the following clause in their policies in order to protect themselves against the loss involved in further depreciation of their national currency:

In the case of controversy arising between the insurer and the insured which is settled before the courts or by arbitration, or in the case of payment on the part of the insurer being delayed by any other reason, the insurer is not to be liable to refund the assured for any damage accruing in consequence of the deferred payment, with exception of legal interest, unless the insurer has acted negligently or wilfully in delaying such payment.

Shipping Board Restricts Averages

IT has been decided by the United States Shipping Board authorities not to have general average statements drawn up in a considerable number of cases where their vessels may have been concerned in casualties giving rise to general average acts. The reason for this action lies in a desire to save the expense incurred in preparing statements in trivial and questionable instances. Claims for loss or damage to cargo resulting from such casualties will receive full consideration. This attitude of the board has been brought to the attention of the proper authorities at Lloyd's, London, and the latter's average department has been taking the necessary steps for putting before the Shipping Board any such claims paid by underwriters of which they may hear after receive notice. Accidents selected by the board for this treatment are those entailing but slight cargo sacrifice. The London Lloyd's is chiefly interested because of relations with Americans.

Current Admiralty Decisions of Special Interest

By Calvert B. Gill*

Limitation of Liability

IN the case of the *Harlow*, Aspinall's Maritime Law Cases, Vol. XV, Part VII, page 498, the Admiralty Division of the English High Court of Justice said, the owner of an unregistered ship is not deprived of the right to limit his liability under Sec. 503 of the Merchant Shipping Act of 1894 by reason of the fact that his ship has not been registered. The right to limit liability extended by Sec. 1, of the Merchant Shipping (Liability of Shipowners) Act, 1898, as amended by Sec. 85, Sched. 2 of the Merchant Shipping Act of 1906 to the owners, builders and other parties interested in any ship built within His Majesty's dominions, is an unqualified right and is not restricted to such period after launching as may be necessary to effect registration. Lighters used for navigation in the transport of goods on the tides, in tow of tugs and upon tides, fitted with rudders and managed by their own crews, are ships within the meaning of Sec. 742 of the Merchant Shipping Act, 1894.

Where damage is done jointly by several vessels belonging to the same owner—e.g., a tug and her tugs, by the negligence of those on board some or one of them, the owner of these vessels is only entitled to limit his liability to the aggregate amount calculated upon the several tonnages of each of the vessels which might have been proceeded against *in rem* in respect of the damage done, since as the employer of the negligent persons he might be held liable for all the damage not only in each action *in rem* but in proceedings *in personam*.

Authority of Ship's Agent

THE authority of an agent for the officers and crew of a King's ship, under the Naval Agency Act, 1864, says the High Court of Justice, Admiralty Division in the case of the *Hermione*, Aspinall's Maritime Law Cases, Vol. XV, Part VII, page 493, is not wider than that of a licitor and does not therefore extend to the settlement of claims by the ship's officers and crew without their express authority. Thus a ship's agent who settles a claim by the officers and crew of a King's ship for salvage reward without the consent expressed or implied of the commanding officer is liable in damages to the extent of the award which the officers and crew would have received if the salvage claim had been duly prosecuted, less the amount received under the terms of settlement. The agent has no authority to settle the claims of the officer (other than the commanding officer) and crew without their instructions when the commanding officer has been giving instructions on their behalf as well as his own, notwithstanding that the commanding officer takes an exaggerated view of their claims.

Seaman's Hospital Treatment

THE Act of Dec. 20, 1920, providing that any seaman brought into the United States and found to be suffering from any of the diseases set out in Sec. 35 of the Immigration Act of 1917, shall be removed to a hospital at the expense of the immigration authorities for treatment, payment for such treatment to be made by the vessel without deduction

from the seaman's wages, is paramount to the treaty between the United States and Norway, which vests exclusive jurisdiction in the Norwegian Consul over disputes for wages occurring on Norwegian ships. United States courts have jurisdiction of a suit for recovery of that portion of the wages withheld by the Norwegian Consul for the purpose of reimbursing the ship for the expenses incurred in the treatment of a seaman under the provisions of Sec. 35 of the Immigration Act of 1917. *Jernberg vs. Young*. American Maritime Cases. Vol. 5, page 426.

Valuation of Shipment in Bill of Lading

IN *Beaumont Export & Import Co. vs. New York & Cuba Mail S.S. Co.*, 286 Federal Reporter, 120, the plaintiff endeavored to recover for the loss of a caterpillar tractor which fell overboard from a vessel of the defendant. The bill of lading, under which the tractor was shipped, limited the value of each package to \$100.00. The Court said, that a provision in a steamship bill of lading issued for a shipment, wherein it was mutually agreed that, unless a higher value was stated, the value did not exceed \$100.00 per package and the freight had been adjusted on such valuation, was valid and binding and limited the damages recoverable for loss of shipment to \$100.00.

Hull of New Vessel Subject to Maritime Liens

WHEN the hull of a new vessel has been launched it becomes a vessel and a subject of maritime jurisdiction and may be subject to liens under the Act of June 23, 1910, Sec. 1 (Comp. St., 7783), says the Court in the *Pinthis* 286 Federal Reporter, 122. A claim for spare or reserve engine parts furnished to a new and incomplete vessel after she was launched, by one other than the contractor for her construction, is not one for construction, but for supplies for which a lien is given by the Act of June 23, 1910.

Due Diligence in Choosing Master Limits Award

WHERE libellant, a young and inexperienced school boy was shipped as an able seaman, though he had never before been to sea, and by reason of the bad judgment of the captain and the negligence of the boatswain, an inexperienced and incompetent man, shipping dunnage in a heavy sea, the libellant working in the hold was injured by a falling beam so that his leg was amputated considerably above the knee, the Court in *Phillips vs. United States et al.*, 286 Federal Reporter 631, said that neither the inexperience of the libellant nor the insufficiency of the equipment contributed to libellant's injury which was the result of gross error in judgment on the part of the master, so that libellant could not recover, where the operators of the vessel showed that the master had the usual certificates and that he had good recommendation and that they exercised due care in choosing him, and libellant was restricted to an award for maintenance and care.

*Attorney at law, Baltimore, Md.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Exhaust Pressures for Main and Auxiliary Engines

Q. (1,199).—Will you please give rules for finding the approximate exhaust pressure of steam leaving a cylinder after doing work therein? Information required for both main and auxiliary engines. T. L.

A. (1,199).—The final exhaust pressure for main and auxiliary machinery is usually decided upon at the start of a design, and all things which might affect this pressure are proportioned to suit.

For instance, in the case of auxiliary machinery, we will say the exhaust steam pressure has been fixed upon as 10 pounds per square inch gage. A branch from this system leads to the condenser and connects to it with a back pressure valve set at 10 pounds gage, so arranged as to relieve into the condenser should the pressure rise above this point. The rate at which the exhaust steam is to be used in heating the boiler feed water and its volume corresponding to 10 pounds gage passing per minute being known, the pipe leading to the heater is so proportioned in diameter as to give a velocity in feet per minute in accordance with accepted practice.

In the case of main engines, the vacuum in the condenser is fixed at the start. We know the pressure at the low pressure exhaust nozzle is from 1 to 1.5 pounds in excess of the pressure corresponding to vacuum. This condition, however, is only brought about by the proper number of expansions and correctly proportioned steam and exhaust passages and valve openings. A restricted exhaust opening would change our expected results greatly.

It is thus seen that the exhaust pressure of steam leaving a cylinder is a direct function of what we choose to make it at the outset rather than any calculations we would make within the cylinder itself.

How to Calculate Indicated Horsepower When Mean Pressures of Cylinders Are Unknown

Q. (1,198).—Will you please show how the indicated horsepower of an engine with the following particulars can be obtained when the mean pressure of each cylinder is not known:

Cylinder	Diameter	
High pressure	27 inches	Revolutions per minute, 72.
Intermediate pressure	45 inches	Steam boiler pressure, 180
Low pressure	74 inches	pounds per square inch.
Stroke	54 inches	

A. (1,198).—In order to answer this question assumptions will be made where data are insufficient. A close enough approximation as to the power may be made without taking into consideration cylinder clearances and piston rod areas.

C_h = cut-off of high pressure cylinder = 70 percent assumed.

A_h = area high pressure cylinder = 572.6 square inches.

A_l = area low pressure cylinder = 4300.9 square inches.

$$R = \text{ratio of expansion} = \frac{A_l}{C_h \times A_h} = \frac{4300.9}{0.7 \times 572.6} = 10.73$$

$$\text{Hypo. log } R = 2.3749$$

Allow 15 pounds drop between boilers and engine.

P = pressure in high pressure steam chest, absolute = 180 pounds.

L = length of stroke, feet = 4.5

Revolutions per minute = 72

$$S = \text{piston speed, feet per minute} = 2 \times L \times \text{RPM} = 2 \times 4.5 \times 72 = 648$$

p = back pressure = 3 pounds, assumed.

P_m = theoretical mean effective pressure referred to the low pressure cylinder, pounds per square inch.

$$= P \times \frac{1 + \text{hypo. log } R}{R} - p = 180 \times \frac{1 + 2.3749}{10.73} - 3 = 53.6$$

E = ratio of actual to theoretical mean effective pressure = (clearance not considered) 0.56 to 0.61 for three cylinder triple expansion engines. Use 0.585.

$$P_r = \text{mean effective pressure} = P_m \times E = 53.6 \times 0.585 = 31.4$$

Indicated horsepower =

$$\frac{P_r \times S \times A_l}{33,000} = \frac{31.4 \times 648 \times 4300.9}{33,000} = 2,650$$

Basic Design Problem

Q. (1,200).—In his last installment of the article on the Dyson method in the August, 1921, issue of MARINE ENGINEERING AND SHIPPING AGE, Dyson says,

"... in choosing the point of design care must be taken to plot chp/EHP well above the basic S curve."

and in the program sheet he has, "v/V for chp/EHP."

Does this mean that the choice of v/V is arbitrary on the part of the designer and bears no relation to chp/EHP at the moment of selection?

Comparing this with an article by Mr. Bates in the April, 1921, issue of MARINE ENGINEERING AND SHIPPING AGE on design of screws for tunnel stern vessel, I find a series,

ehp/EHP	.223	.300	.371	.445	.52
v/V	.652	.714	.771	.822	.869

Is the selection v/V purely at random? The third decimal seems a rather exact figure for random selection. If the v/V value results from initial choice of chp/EHP, how is the value v/V found. Dyson's articles are far from clear on this point, being rather composed for analysis than design.

Again, having sufficient data for merchant ships, assumed as standard, and having derived a chart similar to Dyson's No. 1, how could direction lines be determined for H/B greater than standard, as in Dyson's Fig. 2?

A. (1,200).—I have been unable to find in Admiral Dyson's article of August, 1921, the quotation to which you refer. Your question will, however, be answered.

It is customary after determining the basic slip (S) value to assume various values of chp/EHP with corresponding values of v/V. These values of v/V should be so chosen at a safe distance above the basic slip line that when K is taken into consideration there is no danger of the propeller being in cavitation.

In order to determine in the beginning the largest chp/EHP that can be used with its corresponding v/V with safety, the procedure should be as follows:

First. On Fig. 8 (May, 1921) pick a point on your S curve having an chp/EHP value in the vicinity of what

might be expected for the type of vessel in question. Denote this power factor by $(\text{ehp}/\text{EHP})_g$ and read off the corresponding value of v/V .

Second. Use Curve 4, Fig. 7 (May, 1921). Read values on left hand scale corresponding to $(\text{ehp}/\text{EHP})_g$ which we will call Z_g .

Third. $Z_p = Z_g + \log K$.

Fourth. Again use Curve 4, Fig. 7. Read value on bottom scale of ehp/EHP corresponding to Z_p of the third step. The value of ehp/EHP is the maximum which could be used with the v/V taken with safety.

This propeller would be out of, but close to, cavitation, so to be doubly safe when loaded or in rough weather a value of ehp/EHP somewhat to the left or of v/V somewhat higher up should be chosen as one starting point. A series of such points should be found and used as a basis for design.

Referring to the propeller design of April, 1921, the values of v/V were readings taken on the S curve referred to above and were exact readings from a chart having a much finer scale than that of Fig. 8. The same is true of Fig. 7. While these readings may seem rather exact, yet to get consistent results it is often necessary; especially is this true when it is desired to plot a smooth curve of a propeller's expected performance.

The first part of this answer, I think, shows that the choice of v/V is not at random.

Charts Nos. 1 and 2 hold for merchant as well as naval vessels. It is possible that I do not understand the question.

LETTER TO THE EDITOR

Progress of Welded Construction

LIKE all new methods, especially those of the more radical order, welded construction for marine vessels continues to meet with much opposition on the part of shipbuilders. Strangely enough, the latter appear ever ready to utilize the welding art for their emergency problems whether plant repairs, correction work or new construction. The paradoxical feature of this situation is the ready acquiescence of our inspection bureaus to the use of welding for the repair of worn or damaged pressure parts of boilers, and important strength members in the ships' structure, while the use of welding for new construction of those same parts is strictly forbidden.

As a result of several years' active propaganda, reinforced by very extensive exhibits of laboratory research and practical field operations, the barrage erected in the progress of welding has been gradually weakened so that there now remains in the ammunition chest of the opposition only two "last shots," viz.: "Erection" and "inspection."

Even these appear to be no longer effective as it is recorded, both in historical reports and by photographs, that important structures have been erected and welded in perfect alignment and with absolute metal-to-metal contact without a single perforation of plates for bolting up. The system is so simple and withal inexpensive and efficient that it must eventually be utilized for the assembly of any size or form of structure, whether boss plates, stringer plates or mast fittings, to the exclusion of all present methods.

It is a fact also that the quality of any weld can now be quickly determined by a very simple, inexpensive method without damage to the seam structure. Any inspector or helper of reasonable intelligence can readily master the art and there is no longer any reason why the classification societies need refuse to accept welded construction because of uncertainty regarding the quality of the weld.

New York.

WILLIAM T. BONNER.

American Delegates Appointed to International Navigation Congress

AMERICAN delegates to the thirteenth International Congress of Navigation, which will meet in London in July, under the auspices of the Permanent International Association of Navigation Congresses, have been named by Secretary of State Hughes, following the receipt of an invitation from the British government.

The congress will deal with questions of inland and ocean navigation, largely from an engineering viewpoint. Membership of the United States in the association was authorized by congress in the rivers and harbors act of 1902.

The American delegates, who were selected from government departments concerned with navigation, include the following:

Colonel J. C. Sanford, Corps of Engineers, U. S. A., retired.

Captain Frank T. Chambers, C. E. C., United States Navy.

Colonel J. C. Oakes, Corps. of Engineers, U. S. A.

Major O. N. Solbert, U. S. A., military attache at the American Embassy in London

Captain Charles L. Hussey, naval attache at the American Embassy in London.

Rear Admiral William E. Reynolds, commandant of the United States Coast Guard.

John C. Hoyt, hydraulic engineer, United States Geological Survey.

Colonel E. Lester Jones, director of the Coast and Geodetic Survey.

George R. Putnam, commissioner of lighthouses.

Walter Tower, commercial attache at the United States embassy at London.

Captain W. F. Purdy, operating manager of the United States Shipping Board at London.

Huntington T. Morse, European manager of the Emergency Fleet Corporation.

Inventor of Thermit Welding Dies

PROF. DR. HANS GOLDSCHMIDT, inventor of the widely known thermit process for welding iron and steel and for producing high grade metals and alloys, also originator of many other scientific inventions, died suddenly in Baden-Baden, Germany, on May 20, after a stroke.

Prof. Goldschmidt was born in Berlin, Germany, on January 18, 1861. His father was the proprietor of chemical works and tin smelters which he had founded in 1847. After having been graduated from the "gymnasium" of Altenburg, Hans Goldschmidt studied chemistry, physics and natural sciences in general at the universities of Berlin, Leipzig, Heidelberg, Strassburg and at the Institute of Technology at Charlottenburg.

In 1887 Prof. Goldschmidt entered the firm of Th. Goldschmidt, Essen Ruhr, Germany, in joint partnership with his brother Dr. Karl Goldschmidt. The attention of the latter was applied mainly to the business management of the company, while Prof. Hans Goldschmidt devoted himself to scientific research. Under their joint guidance the firm grew to international importance, with agencies and allied companies throughout the world.

Prof. Goldschmidt visited this country very frequently and was president of the Goldschmidt Thermit Company, now Metal & Thermit Corporation, from 1904 to 1916.

JOHN GILBERT WARD, treasurer of the Babcock and Wilcox Company, New York, died on April 22.

PERSONAL MENTION

J. C. CLIFFGUARD, assistant manager of the department of construction and repairs of the Standard Oil Company, is in Europe investigating different types of Diesel engines.

JAMES McNAUGHT, vice-president of Esplen Sons & McNaught, naval architects and marine engineers, has been sent to various European countries by the Standard Oil Company to report on the Diesel engines as manufactured abroad.

J. K. HUTCHISON, until recently chief engineer of the steamship *Maracaibo*, has been appointed chief of the new passenger and freight ship *Carabobo*, under construction for the Red D Line at the New York Shipbuilding Corporation's yard, Camden, N. J.

W. J. GIBSON, who has been appointed chief steward of the *Leviathan*, is considered by many shipping executives to be the dean of all stewards. Mr. Gibson's first appointment as a chief steward was on the *Britannic* of the White Star Line when she was employed in carrying troops to the Boer war in 1901. He served in this capacity until the end of the war when he was transferred as chief steward to the old *Majestic* of the White Star Line. In 1903 he was again transferred as chief steward of the *Ionic* which at that time was on the New Zealand route. After service on the *Ionic* for over a year he joined the *Teutonic* on the New York route. Some months later he was transferred to the *Cretic* in the Mediterranean service and, while in this service, he also served on the *Republic*. In 1907 he was transferred as chief steward to the *Celtic* which at that time was one of the principal liners on the New-York run. He served three years on the *Celtic* and then went to the *Baltic* in 1910. In 1911 he was transferred to the *Adriatic* and in March, 1912, he assumed the duties of chief steward on the steamship *Olympic*, which is now one of the principal vessels of the White Star Line. Mr. Gibson remained on the *Olympic* until he decided to become an American citizen, whereupon he resigned and came to America. His first position in America was as chief steward on the *Finland* of the American Line. At the outbreak of the war he was appointed purchasing agent for the Shipping Board at Baltimore where he remained until the armistice was signed. He then accepted the position of supervising chief steward of the International Mercantile Marine Company until he was offered and accepted the position as chief steward on the *Leviathan*.

GEORGE F. MURPHY, formerly Pittsburgh manager of the Heine Boiler Company, has been placed in charge of the New York office of this company upon the retirement of Paul H. Brangs and the resignation of his son, Harold A. Brangs. Mr. Murphy will be assisted by J. L. Daly and G. A. Knowles.

ROBERT H. LAVERIE, president of Robert H. Laverie, Inc., consulting engineers, hull, machinery and cargo surveyors, 17 State street, New York, announces that his company has

taken over Messrs. Banghart and Shaumburg (formerly connected with Price, Banghart and Company) and has established a cargo division which will be under the direct supervision of Charles M. Banghart.

OBITUARY

JESSE L. WHEELER, formerly a shipbuilder and designer in the New York Navy Yard, Brooklyn, N. Y., died recently at his home in Brooklyn, aged 89.

CAPTAIN GEORGE COLLINS, river pilot, and formerly captain of one of the Wilson Line boats plying between Philadelphia, Pa., and Wilmington, Del., died at his home in Philadelphia on May 17.

FRANK E. WING, secretary-treasurer of the L. S. Starrett Tool Company, and secretary of the Athol Machine Company, Athol, Mass., died on May 13, following a long illness, aged 58. Mr. Wing's entire business life was spent with the Starrett company.

JAMES WOLLEY, one of the best known figures of the North Atlantic waterfront and head of the Commercial Towing Company, since it succeeded the Commercial Towing Company in 1887, died recently at his home in East Boston, Mass., aged 85 years.

CAPTAIN BENJAMIN A. SMITH, who for a quarter of a century has been a principal figure in the Gloucester fishing industry and who was instrumental in putting Gloucester fishing schooners into the races for the international championship, died May 7 at his home in Gloucester, Mass.

CAPTAIN FRANCIS G. COXON, marine superintendent of the Booth Steamship Company, died recently at his home in Brooklyn, N. Y., at the age of 62. Capt. Coxon was born in England and came to this country 16 years ago and for many years was in the employ of the Booth Steamship Company.

WILLIAM SHREEVE DORAN, president of the Alberger Pump and Condenser Company, New York, died at his home in that city May 12 after a few months' illness, at the age of 58. He was born in Bristol, Pa., and early in his career became identified with the steam pump making concern of Henry R. Worthington. For years he was regarded as one of the country's authorities on condenser operations. He was long a member of the Engineers' Club and since 1921 was vice-president.

REAR-ADMIRAL WILLIAM SHEFFIELD COWLES, 76 years old, brother-in-law of former President Theodore Roosevelt, died at his home in Farmington, Conn., on May 1. During the Spanish war Rear-Admiral Cowles was in command of the gunboat *Topeka*. He was retired on August 1, 1908, after 45 years in the naval service. At that time he was chief of the Naval Bureau of Equipment and a member of the Board of Construction. During President Roosevelt's administration Rear-Admiral Cowles, then a commander, was the President's naval aide.

CAPTAIN ALEXANDER McDougall, seventy-eight years old, internationally known shipbuilder and inventor, died on May 23 at his home in Duluth, Minn., following an operation. Captain McDougall, after sailing the Great Lakes for twenty years, obtained the assistance of Captain Thomas Wilson, of Cleveland, in building the first whale-back. As president of the McDougall-Duluth Company, during the war, he directed construction of a large fleet of lake freighters and steamers for the Great Lakes and coast-wise trade.

Shipping Problems Discussed at Marine Association Banquet

AT the spring banquet of the American Marine Association, which was held at the Waldorf-Astoria, New York City, on the evening of May 3, Frank J. Shipman, acting president of the association, outlined the aims and achievements of the organization and introduced as toastmaster Mr. Charles H. Potter, president of the United States Ship Operators Association. Sounding the keynote of the evening as the American merchant marine Mr. Potter introduced Senator Royal S. Copeland, of New York, who expressed the opinion that the merchant marine would be of little use without freight or cargo and suggested it was first necessary to rehabilitate the nations of the world so that commerce of the world could resume its normal flow. Replying to Senator Copeland, Stevenson Taylor, president of the American Bureau of Shipping, pointed out the fact that if we wait for the resumption of the world's commerce some other nation would carry it.

Alfred G. Smith, president of the American Steamship Owners Association, vigorously opposed direct government operation of ships and stated that the only way out of present difficulties is for the Government to sell its vessels as rapidly as possible, retire from business as soon as possible and provide regulations to make private competition possible. He pointed out that direct government

(Continued on page 380)

Twenty-four Millions to Be Asked By Shipping Board for New Ships to Replace *Agamemnon* and *Mt. Vernon*

A POSSIBLE expenditure of \$24,000,000 for the construction of two new passenger ships for the transatlantic service, to operate in conjunction with the *Leviathan*, is seen in the latest resolution from the Shipping Board, in which it is considered too costly to recondition the *Agamemnon* and *Mount Vernon* at a total estimated price of close to \$16,000,000, the plan to construct two new ships of a similar type at a total cost of about \$24,000,000 being substituted.

Plans and specifications for the reconditioning of the *Agamemnon* and *Mount Vernon* have been under preparation by the firm of Gibbs Brothers, Inc., 1 Broadway, New York, and were understood to be rapidly nearing completion. It was stated that the principal work to be carried out under the proposed specifications included the construction of "blister" tanks on the port and starboard sides of each of the hulls extending about three-quarters of the length of each vessel, tapering in to present lines and designed to increase the stability of the ships as well as furnishing space for the carrying of fuel oil and ballast. The ships

were also to be converted from coal to oil burners, which would involve a great quantity of piping, valves, pumps, etc.

The resolutions made by the Shipping Board with regard to these two ships were announced as follows:

"Whereas it had originally been contemplated that the reconditioning of the *Agamemnon* and the *Mount Vernon* in order to place them in transatlantic service in conjunction with the *Leviathan* would require an expenditure of a maximum of \$4,000,000 per ship; and

"Whereas careful plans and estimates prepared upon order of the United States Shipping Board and now just submitted show that a minimum of \$8,000,000 per ship will be required for such purpose; and

"Whereas it is estimated that new ships of modern construction and similar type would cost \$12,000,000 per ship; it is hereby

"Resolved, That the United States Shipping Board regards an expenditure of \$8,000,000 per ship for reconditioning twenty-year-old vessels when \$12,000,000 would construct new ships of similar type, as not justified; therefore be it further

"Resolved, That the *Mount Vernon* and

Spring Dinner of the American Marine Association at the Waldorf Astoria Hotel, New York, on May 3

the *Agamemnon* not be reconditioned, but that in the next budget the United States Shipping Board will make request of Congress for such additional appropriation as would be required for the construction of two modern ships, smaller in size than the *Leviathan*, but comparable in every way for transatlantic service in conjunction with the *Leviathan*."

Eastern Company's New Program to Cost \$3,500,000

NORFOLK, Va. (Special).—Plans of the Eastern Steamship Lines for financing extension of service of their lines, among which is the Old Dominion Transportation Company operating between this city and New York, have been approved by stockholders, according to information just received from Boston.

The company will issue new stock to provide \$3,500,000 for carrying out the program decided upon since the acquisition within the last two months of the Old Dominion Transportation Company, and the Old Dominion Steamship Company, which formerly operated on the Norfolk-New York route.

Not only will Norfolk get a daily service to New York, but other lines operated by the Eastern Steamship Lines will be given additions and improvements in service.

Shipping Board Increases Seamen's Wages

AFTER several conferences between the representatives of the United States Shipping Board and representatives of the International Seamen's Union with reference to wages and conditions of seamen on Shipping Board vessels, and after thorough investigation by the Board the following increase in seamen's wages were announced, effective May 14, with certain changes in working conditions such as the inauguration of the three-watch system instead of the two-watch system and the observance of the eight-hour day in port:

	Old Scale	New Scale
Carpenter	\$70.00	\$80.00
Carpenter's mate	60.00	70.00
Boatswain	65.00	75.00
Boatswain's mate	60.00	70.00
Quartermaster	60.00	70.00
Able seaman	55.00	62.50
Ordinary seaman	40.00	47.50
Storekeeper	60.00	70.00
Deck engineer	70.00	80.00
Pumpman	70.00	80.00
Donkeyman	65.00	75.00
Storekeeper	65.00	75.00
Oiler	65.00	72.50
Fireman:		
Oil burner	57.50	65.00
Coal burner	57.50	67.50
Coal passer	50.00	60.00
Wiper	50.00	57.50
Watertender	65.00	72.50

Shipping Problems Discussed at Marine Association Banquet

(Continued from page 379)

ment operation is impractical and therefore unwise but that by open and frank deliberation between government representatives and private operators the shipping problem might be gradually worked out.

Joseph E. Sheedy, vice president of the Emergency Fleet Corporation, gave a detailed account of the constructive measures carried out by the Shipping Board in the operation of its vessels.

Proposed Oceanic Ships Are to Be Modernly Equipped Passenger and Cargo Carriers; Details of Construction

FINAL decision as to whether or not the Oceanic Steamship Company, of San Francisco, Cal., will build two new passenger and cargo ships for the San Francisco-Australia service, is expected in the near future, according to official information obtained by MARINE ENGINEERING AND SHIPPING AGE. Frederick S. Samuels, assistant to the president of the company, has been in Washington with the proposal to the Shipping Board and the Postmaster General that the company will build these ships if they can obtain a reasonable compensation under Section 24 of the Marine Act of 1920

and providing that the cost of construction is not excessive. Although plans and specifications are ready to go out the bids will not be asked until favorable action is taken.

The proposed vessels are to have an overall length of 500 feet, propulsion to be by two Curtis turbines, direct-connected generators (3,640 R. P. M.), and two synchronous motors (5,000 S. H. P.), steam being supplied by six B. & W. watertube boilers burning oil for fuel.

The ships, if built, are to be put into the San Francisco-Honolulu-Pago Pago-Sydney service. The principal data concerning the proposed ships is as follows:

CHARACTERISTICS

Length, over all.....	500'-0"
Length, B. P.....	475'-0"
Beam, molded.....	63'-0"
Depth M. L. D. to Upper Deck..	40'-0"
Load Draft.....	25'-0"
Block coefficient at 25'-0" draft.	0.631
Midship coefficient at draft.....	0.974
Prismatic coefficient at draft....	0.648
Speed	18 K.
Cruising Radius @ 15 K. 25' D.

America Must Build
MotorshipsShipowners Cannot Safely Ignore
Possibilities of Diesel Propelled Vessels

DECLARING that his recent trip abroad, in which he visited every important manufacturer of Diesel engines, had been a revelation to him, Mr. A. S. Hebble, superintendent engineer of the Southern Pacific Lines, told the Propeller Club at a recent luncheon that he had learned a great many things about the Diesel that he had not known before.

Although I called at the shipyards and repair plants of practically all the maritime countries, said Mr. Hebble, I could only find two motorships undergoing repairs. The Diesel engine, he asserted, is not such a complicated affair as some would have us believe, and we should have little difficulty in securing efficient operating engineers.

A significant indication of the trend toward motorships in Europe, Mr. Hebble declared, is the fact that one of the greatest English shipping executives has recommended that our company shall not build any more steamers. Another point that he brought up was that while there are 876,000 tons of motorships in commission there are now 1,000 tons under construction.

Practically every bit of trouble that has been experienced with motorships, Mr. Hebble pointed out, has been due to poor fuel. The time when we can use Mexican crude oil in Diesel engines is still far off, he declared. If this was not so we would

Cable Supply Ship Dickenson Completed

Vessel, Designed by Cox & Stevens, New York, Leaving Sun Shipyard on May 23 for Honolulu with Captain Piltz in Command

Dining Room

Staten Island Shipbuilding Co.
Is Low Bidder for Construction
of New York Central Ferryboat

THE Staten Island Shipbuilding Company submitted the lowest bids for the construction of a steel ferryboat for the New York Central Railroad Company at the opening of tenders on May 15. Two sets of prices were offered, one providing for equipment with machinery supplied by the W. & A. Fletcher Co., Hoboken, N. J., the other for machinery supplied by the builder. Staten Island's price in the former case was \$479,700 and in the latter \$469,700.

The vessel, which was designed by J. W. Millard & Brother, of 17 State street, is to have a length over guards of 210 feet, beam over guards 66 feet 2½ inches, depth amidships 17 feet 6 inches. Propulsion is to be by two direct-acting 2-cylinder compound, jet condensing steam engines, 19 by 38 by 28 inch stroke, steam to be supplied by two Scotch return tube boilers with steam pressure at 150 pounds. Proposals were submitted from seven yards.

never build another steamer. Some Diesel engine manufacturers claim that their engines will operate on crude oil but, in his opinion, nothing but the best grade of fuel oil should be used.

Pa. Second bids were opened on March 28, the Crook Company's price in this case being \$174,240.

Tug Contract Awarded

The contract for the construction of the single screw steel towboat *John Wanamaker* has been awarded the H. E. Crook Company, Inc., of Baltimore, by the Department of Wharves, Docks & Ferries, Philadelphia,

Bids June 22 for Four
Motor Tugs

The United States Engineer Office, 815 Witherspoon Building, Philadelphia, Pa., will receive bids until June 22, 1923, for constructing and delivering four 50-foot steel motor tugs. Information on application.

Atlantic Coast Shipbuilders Elect Officers

At the annual meeting of the Atlantic Coast Shipbuilders' Association held in Philadelphia, Monday, May 14, Harry A. Magoun, vice-president of the New York Shipbuilding Corporation, was elected president of the Atlantic Coast Shipbuilders' Association to succeed J. L. Ackerson, of the Merchants' Shipbuilding Corporation. Chas. P. Wetherbee, of the Bath Iron Works, was elected vice-president, J. Harry Mull, of the William Cramp & Sons Ship and Engine Building Company, was elected treasurer, and Clarence S. King was re-elected secretary.

The following were elected members of the executive committee: W. G. Coxe, chairman; J. H. Mull and J. G. Pew.

Chamber of Commerce Opposes Government Operation of Ships

THE following resolutions, submitted by the Marine Bureau of the Chamber of Commerce of the United States, relative to the merchant marine, were unanimously adopted at the annual meeting of the National Chamber held last month in New York:

MERCHANT MARINE

It is necessary for the national defense and the proper growth of foreign and domestic commerce that the United States should have an adequate merchant marine, ultimately to be owned and operated privately by citizens of the United States. The Chamber is unalterably opposed to the Government engaging in commercial business, for the reason that such a course is economically inefficient, is against public interest and is in contravention of the fundamental purposes of the Government.

The Chamber therefore urges upon the President of the United States and the Shipping Board that, before the Board enters upon the commercial venture of direct operation of its Government-owned ships, further efforts should be made by counsel and collaboration with responsible shipping interests of the United States to evolve a plan by which the ships necessary to maintenance of essential services may be operated by private citizens of the United States, with a view to their acquisition and ownership by citizens as soon as they can be made self-sustaining.

To this end we ask careful consideration of the possibility of relief of private American shipping interests from inequality in world competition, believing that relief is obtainable through the relaxation or removal of burdensome restrictions without departure from proper requirements for public safety.

OCEAN BILLS OF LADING

The last annual meeting testified to the Chamber's continuing interest in the Hague rules respecting the bills of lading under which merchandise is carried by sea. These rules should result in rights and liabilities as between vessels and shippers which are equitable to both, are suited to the conditions of carriage of goods by sea and are calculated to facilitate the use of ocean transportation. After a year of discussion the Hague rules were, in the latter part of 1922, revised in order that they may further promote these purposes. In the revised form they have been accepted by a diplomatic conference, in which the United States was represented. Appropriate action should be taken for ratification of these rules, in order that further progress may be made.

Over Twenty-two Millions to Be Spent in Port of Houston, Texas, Including Piers and Equipmen

MUNICIPAL and private enterprises are planning and carrying out improvements in the Port of Houston, Tex., which will cost considerably in excess of twenty-two and one-quarter million dollars, according to official information obtained by MARINE ENGINEERING AND SHIPPING AGE. Among the activities of the private enterprises, the Houston Lighting and Power Company, through its president, E. B. Parker, has just announced that their new electric power plant, on which construction has been commenced on the Houston Ship Channel, will be of an ultimate capacity of 200,000 kilowatts and will involve an expenditure during the next five years of approximately \$10,000,000. This plant will use crude oil for fuel and will have their own storage tanks together with their own wharf, which will be equipped to handle oil from tank steamers.

The Sinclair Refining Company is now actively engaged in the construction of a wharf of creosoted timber, 1,000 feet in length and 50 feet wide, at their refineries' site on the Ship Channel. The company is also installing two new batteries of high pressure stills and it is understood that their building program for the next seven months contemplates the outlay of \$1,000,000 per month, which includes pipe line connection about to be completed between their plant and the North Texas and Oklahoma oil fields with an extension to the fields of Wyoming.

\$4,000,000 BOND ISSUE

As previously announced in these columns, the Harris County Houston Ship Channel District has voted a bond issue of \$4,000,000 for the construction of six new wharf units, approximately 500 feet in length each, and a 1,000,000-bushel grain elevator with workhouse and machinery design, to handle 6,000,-

000 bushels and the additional storage to be added as needed. The Port Commission advertised for bids to be opened May 7, the dry excavation on the site of the wharves, amounting to approximately 100,000 cubic yards, and also for the construction of two large storm sewers to provide drainage for the areas back of the wharves. A contract has been let to the J. S. Metz Company for the engineering and design of the million-bushel grain elevator. The hydraulic dredging on the north side of the harbor along the site of the wharves is now under way with government plants and a government contract will be awarded in near future to complete this part of the work.

Three sets of mooring clusters with ways to shore have just been constructed adjacent to the Manchester wharf to provide a berth for vessels waiting their turn at the wharf. A carrier house with 1,000 bushel elevator and flour mill of the Houston Mill & Elevator Company to the Port Commission's Manchester wharf and will be ready to handle grain shipments in the coming season.

CHANNEL WORK

An allotment of \$1,100,000 from the river and harbor bill has been made for the extension of the 30-foot depth in the Houston Ship Channel and when contracts are awarded covering this sum there will only be approximately two miles additional work to be done, thirty-eight miles out of the total length of fifty miles having already been completed. Plans and estimates for the construction of about five miles of Public Belt Railroad along the north side of the channel.

PRIVATE ENTERPRISES

The Anderson Clayton Company has completed the dredging work for their wharf and pilings are now being driven. The two-story concrete sheds, consisting of ten units 100 feet by 150 feet with high density cotton compress in the center, are under construction. These sheds will be built of reinforced-concrete equipped with sprinkler system and electric trolleys for rapid handling of cotton. The wharf will be 1,525 feet in length and the entire project is to be ready for operation by August of this year.

The Alexander Sprunt Company, operating the Ship Channel compress a short distance below the Anderson Clayton plant, is contemplating the construction of a wharf 800 feet in length with suitable shed for rapid handling of export cotton.

The Texas Portland Cement Company announced recently that they propose to increase the capacity of their cement plant from 700,000 to 800,000 barrels per year while the Galena Signal Oil Company is understood to have under contemplation some extensive additions to their oil refinery on the Ship Channel. The Houston Oil & Refining Company is steadily adding to the capacity of its plant at Baytown, twenty miles down the Ship Channel from Houston.

The Houston & Refining Company recently installed new stills and a new plant, involving a cost of about \$100,000, and two weeks ago shipped a full cargo of case oils and gasoline to Australia from the Port of Houston.

Business Notes

The San Francisco office of The New London Ship and Engine Company, of Groton, Conn., has been moved to 203 Balfour Building and is in charge of S. Burke Smith.

The American Balsa Company, Inc., has announced a change of address and telephone number to 152nd and Exterior streets, New York City; telephone, Mott Haven 1393.

The Manitowoc Shipbuilding Corporation, Manitowoc, Wis., has added another section to its steel floating dry dock that will enable the company to dock vessels up to 500 feet.

The Sprague Electric Works of the General Electric Company has consolidated its district and local offices with corresponding offices of the General Electric Company.

The New York office of the Aero Alarm Company has contracted to extend the Aero alarm system on the steamships *America* and *President Adams*. The Seattle office has contracted to extend the Aero alarm system on the *President Madison*.

William M. Connelly, formerly a marine lawyer, has been appointed manager of the steamer *Fordonian*, offices at No. 822 Marine Trust Building, Buffalo. The *Fordonian* is said to be the only Diesel electrically propelled boat on the Great Lakes. She has a carrying capacity of 3,800 tons.

Foreign Shipping and Shipbuilding Activities

Provisional Program of Institution of Naval Architects' Summer Meeting in Holland

September 1. Arrival at Flushing at 4 p.m.*
September 2. Trip to Middelburg, Veere, lunch at Domburg. Return to Flushing.
September 3. (a) Visit to the Royal Shipbuilding and Engineering Company, "de IJchelde," Flushing. Lunch given by "de IJchelde." Council Meeting. Papers to be read and discussed. (b) Visit to Middelburg. Leave about 4 p.m. Arrival Scheveningen (near The Hague)† at 7.30 p.m.
September 4. Day trip to Amsterdam. (a) Visit to Amsterdam Dry Dock Company, or Netherland Dry Dock Company. Lunch given by Netherlands Shipbuilding Company. Visit to the Netherlands Shipbuilding Company and to the Netherlands Machinery and Railway Material Factory Werkspoor." (b) Visit to Volendam & IJcken. (c) Visit to The Rijksmuseum and the Historical Nautical Museum. Return to Scheveningen.

September 5. (a) The Hague. Papers to be read and discussed. (b) Sight seeing. Visit to Mutters Ship Decorative Works at 4 p.m. (tea at Mutters).

September 6. (a) Visit to Gusto Works, IJcken. Visit to Rotterdam Dry Dock Company. Lunch given by New Waterway Shipbuilding Company. Visit to the New Waterway Shipbuilding Company and to IJcken's Engineering and Slipways Company. (b) Visit to Leyden and trip to the IJcken District.

September 7. Visit to Rotterdam Nautical Technical Institute and Museum. (a) Trip through Rotterdam Harbor. (b) Visit to IJcken Burgerhout Works. Lunch given by IJcken Burgerhout Shipbuilding and Engineering Company. Return to Scheveningen. Reception and tea given by Koninklijk Instituut van Ingenieurs. Official Dinner given by the Institution of Naval Architects.

September 8. Return from Flushing to IJckenstone or Dover. Lunch on board the mailsteamer *Insulinde*, given by Mr. B. E. IJcken, manager of the Rotterdamsche Lloyd.

*The reception committee will provisionally reserve hotel accommodation at Flushing and Scheveningen for as many as signify their intention of taking part in the meetings. Rooms will be definitely allocated at a later date.

†Alternative visits are indicated by letters (a) (b) (c).

First German de Luxe Steamer to Enter Transatlantic Service Since the War

The *Albert Ballin*, which will be the first German de luxe to be placed in the transatlantic service by a German company since the war, is now nearing completion at Hamburg from which port she is scheduled to sail for New York on July 5. The *Albert Ballin*, and her sister ship the *Deutschland*, which will go into service later in the year, 22,000 tons gross register, and embody latest ideas of marine construction, notably a new stabilizing device which combines an anti-rolling tank and the bilge bulge. This device has already been successfully applied to naval craft but the *Albert Ballin* will be the first liner to have it.

Atlantic Transport Line to Resume Passenger Service

RESUMPTION by the Atlantic Transport Line of its direct passenger service between New York and London is one of the outstanding events in ocean steamship travel for 1923.

The original "Minne" class ships—the *Minnewaska*, *Minnetonka*, *Minneapolis* and *Minnehaha*—having been lost in the war, a new class of four ships, preserving all the essential features that made the old vessels popular, but of greater size and with every improvement essential to modern ocean-travel comfort, are being now created to take their places.

NEW VESSELS BUILDING

First of these vessels to be completed is the *Minnewaska*, 21,000 tons, which was launched on March 23, 1923, at the Harland & Wolff Works, Belfast, Ireland, and scheduled to make her first sailing from London to New York on August 4, 1923.

MAIN PARTICULARS

Length	626 feet
Beam	80.37 feet
Depth	54 feet
Gross tonnage	21,000 tons
Cargo capacity	17,000 tons
Horsepower	15,000
Speed	17 knots
Number of boilers (oil burning)	12
Propelling machinery	Twin screw turbines
Number of passengers	369

NEW YORK-LONDON SERVICE

According to Atlantic Transport Line practice, the itinerary of the new ships will be the same as that of the old, namely, New York-London, London-New York direct, without stops at intermediate ports of call. The ships will sail from Pier 58, near the foot of Sixteenth street, New York City, on their eastward voyages, and from the new King George V docks, directly at the door of the world's metropolis, when westward bound.

PASSENGER ACCOMMODATIONS AMIDSHIPS

On these new ships all passenger quarters are amidships, four decks in all being devoted exclusively to passenger accommodation. A deck is given over entirely to public rooms. B deck is occupied principally by suites and the larger staterooms. The dining saloon and reception room are on D deck.

International Navigation Week at Gothenburg, Sweden

Gothenburg, Sweden (Special).—Plans have been completed for a series of international conferences and special exhibitions for "Navigation Week," at the Tercentenary Jubilee Exposition in Gothenburg, Sweden. Navigation week begins on August 1, and during the week conferences of shipowners, shipbuilders, marine underwriters, and others connected with navigation will be held. The most important of these is the International Navigation Congress which will be held under the auspices of the British Chamber of Shipping.

Gothenburg, as Sweden's leading seaport, has spared no pains to make this navigation week of international importance. In connection with the Jubilee Exposition there is a special exhibit devoted to navigation and

Canadian Government Canal and Harbor Work to Cost \$15,000,000

ACCORDING to latest announcement, the Dominion Government, Ottawa, Canada, has in contemplation \$14,962,300 worth of canal and harbor improvements, etc., for 1923. The following work is planned: Construction on Welland Ship Canal, \$12,200,000; improvements \$100,000; new construction on Trent Canal \$210,000; improvements \$309,000; improving Chambly Canal \$48,000; Lachine Canal \$56,000, and Soulanges Canal \$216,000; new steel gate lifter on Sault Ste. Marie Canal \$5,000; improving Port Arthur and Ft. William harbors \$135,000; St. John Harbor \$860,000; Toronto Harbor \$433,000; Matane Harbor \$100,000; repairs to Chicoutimi Wharf \$29,500; L'Islet Wharf \$25,000; Point aux Trembles Wharf \$30,400; St. Michel de Bellechasse Wharf \$25,000; extending wharf at Grand River \$29,000; new wharves at Grondines \$62,000; Haileyburg \$26,400; breakwaters and piers at Cobourg \$28,600; Port Colborne \$200,000; Toronto Island \$30,000; Whitby \$27,500; new cable for Vancouver Island telegraph and telephone lines \$5,500.

Canadian Pacific Vessels to Make Five Winter Cruises in 1924

ACCORDING to a recent announcement, the Canadian Pacific Railway, instead of chartering its ships during the winter months, will operate them in the following five winter cruises in 1924:

The *Empress of Canada*, of 33,000 tons displacement, 22,000 tons gross, will sail from New York, on January 30, on a cruise around the world. The minimum rate from and to any starting point in the United States, no matter where, will be \$1,600, and for the comfort of passengers the number taken will not exceed 500.

The *Empress of Scotland*, of 35,500 tons displacement, 25,000 gross tons, will leave New York, on January 14, on a cruise to the Mediterranean, Egypt, the Holy Land and Europe. The minimum rate for the round trip, New York to New York, will be \$800, and the number of passengers will be limited to 600 to avoid discomfort.

For the third consecutive year the Canadian Pacific will operate two winter cruises to the West Indies and South America. The *Empress of Britain*, of 22,000 tons displacement, 15,850 gross tons, will leave New York, on January 20 and February 20, 1924, for the West Indies, Nassau, Bermuda, Panama and Venezuela. Each trip will be about 30 days and minimum fare \$250.

The fifth cruise will be called "around America," and will be from Vancouver to New York, via the Panama Canal, the *Empress of Canada* being the ship chosen.

the history of navigation, where modern shipping may be seen in the perspective of its historical development.

Captain Olof Traung, director of the Gothenburg Marine Museum, is in charge of the marine exhibits. In this he has had the able advice and assistance of Admiral Hagg, the grand old man of the Swedish navy, now retired.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPBUILDING AND REPAIRS

Repairs, Norfolk, Va.—The American steamship W. M. Irish was taken to Newport News for repairs.

Propeller, San Francisco, Cal.—The Crowley Shipyard has installed a new propeller on the tug Three Sisters.

Overhauling, Newport News, Va.—The Norwegian steamship Erle is at the Newport News shipyard for repairs.

Yacht Repairs, Jacksonville, Fla.—The yacht Firebird was taken to Merrill-Stevens Drydock Company for repairs.

Repairs to Stern Tube, Cleveland, O.—Steamer Mauna Loa was placed in No. 1 drydock for repairs to her stern tube.

Dump Scows, Oswego, N. Y.—The United States Engineering Corps is having three new dump scows assembled at Oswego, N. Y.

Steamer Drydocked, Buffalo, N. Y.—The steamer Ben Maple has been in the Buffalo drydock for examination and minor repairs.

Overhauling Tug, Jacksonville, Fla.—The tug General R. H. Jackson was awarded to Merrill-Stevens Drydock Company for repairs.

General Overhauling, Oakland, Cal.—The steam schooner Tamalpais has been taken to the Hanlon Shipyard for general overhauling.

Docked for Repairs, Lorain, O.—The steamer George B. Leonard, which wintered at Erie, Pa., will be docked at Lorain for repairs.

Lightship Repairs, Chelsea, Mass.—Boston lightship has been withdrawn and has been taken to Chelsea to undergo necessary repairs.

Miscellaneous Repairs, New Orleans, La.—The U. S. naval cutter Comanche has been taken to New Orleans to undergo miscellaneous repairs.

Repairs Completed, Savannah, Ga.—The Wilkinson Machine Works has completed repairs to the Norwegian motorship Johan Ludwig Mowinckle.

Liner Drydocked, Brooklyn, N. Y.—The American liner St. Paul has been drydocked at the Brooklyn Navy Yard for painting and scraping of the hull.

Inspection and Drydocking, San Francisco, Cal.—The Broad Arrow, of the E. R. Rich & Company, is at the Bethlehem yards for inspection and drydocking.

Battleship Repairs, Charlestown, Mass.—The battleships Delaware, Utah and North Dakota have proceeded to the Charlestown Navy Yard for minor repairs.

Dredge Repairs, Savannah, Ga.—One of the dredges of the Globe Dredging Company has been at the yard of the Wilkinson Machine Company for repairs.

Preparation for Service, Oakland, Cal.—The West Camargo, one of the Government's idle ships, was taken to the Moore shipyard to be prepared for service.

Testing and Inspection, San Francisco, Cal.—The Shipping Board tanker Lio has been placed on the Bethlehem ways for testing of her tanks and for inspection.

New Boiler, Buffalo, N. Y.—Tashenberg Brothers Boiler Works, 45 Illinois street, Buffalo, is building a new boiler for the tug Squaw, owned by James Conlon, Buffalo.

General Repairs, San Francisco, Cal.—The Main Iron Works was awarded the contract for carrying out general repairs on the Pacific Mail liner Venezuela. Price \$574.

Contract Awarded, Oakland, Cal.—The Moore Drydock Company was awarded the contract for general repairs to the Pacific Mail liner President Pierce, with a price of \$16,958.

Low Bidder, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation submitted the lowest bid for repairs to the Shipping Board steamer Bearport, with a price of \$2,085.20.

Annual Inspection, Newport News, Va.—The Old Dominion Transportation Company's steamer Hamilton has been taken to Newport News to be drydocked for annual inspection.

Contract Awarded, Baltimore, Md.—The contract for repairs to the steamer West Cobalt, of the Blake Steamship Company, was awarded to Theodore H. Rohde, Inc., at a price of \$2,215.

Steamer Repairs, Charleston, S. C.—Steamship Cotopaxi, of the Clinchfield Navigation Company, has been taken to the yard of the Charleston Dry Dock & Machine Company for repairs.

Overhauling and Extensive Repairs, San Francisco, Cal.—The steamer Siskiyou recently sailed for San Francisco, leaking badly, where she was to be drydocked for overhauling and extensive repairs.

Propeller Repairs, San Francisco, Cal.—The new Electric Line steamer Cuba has been at the Bethlehem Shipbuilding Corporation's yards for repairs to her propeller, which was found cracked in the hub.

Steamship Launched, Seattle, Wash.—The steamship Alaska, first passenger vessel of more than 200 feet in length to be built on the Pacific Coast, was recently launched from the Todd Shipyards, Seattle.

Steamer Damaged, Buffalo, N. Y.—The steamer Victor, a coal carrier on the Great Lakes, suffered \$1,500 damage in a recent fire in the forecastle. The boat is owned by the Interlake Steamship Company.

Miscellaneous Repairs, Chester, Pa.—To have miscellaneous repairs made, the steamship Persia, of the Merchants & Miners Line, has been drydocked at the Sun Shipbuilding & Dry Dock Company's yards.

Steamers Damaged, Lake Superior.—Steamer William Livingstone and whaleback Frank Rockefeller recently stripped the buckets off their wheels in the ice on Lake Superior, according to reports reaching Buffalo.

Transport Repairs, San Francisco, Cal.—With a price of \$9,338, the United Engineering Works was low bidder for certain repairs on the transport Cambrai, now at the Moore Drydock for cleaning and painting.

Steamship Conversion, Camden, N. J.—The steamship Ashbee is being converted into a motorship at the yards of the New York Shipbuilding Corporation and negotiations are being conducted for the sale of the ship.

Contract Awarded, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was awarded the contract for repairing the Shell Company's oil barge Martinez, damaged in collision. Price \$4,998; six days' time.

Vessel Damaged, Savannah, Ga.—The Coast Guard cutter Yamacraw was in collision with the Isbega in the Savannah River recently. The Isbega was operated by the U. S. Engineers and was considerably damaged.

Turbine Generators, San Francisco, Cal.—With a price of \$7,338, the Bethlehem Shipbuilding Corporation was low bidder for installing larger Westinghouse turbine generators on the Pacific Mail liner President Wilson.

Battleship Overhauling, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation has been notified that the battleships New York, Idaho, Pennsylvania and Mississippi will be sent to Hunter's Point in July for overhauling.

General Repairs, San Francisco, Cal.—The steam schooner Katherine has been placed on the Bethlehem ways for general repairs. The Daily Freeman has also been taken to the same yard for overhauling and cleaning.

Steamer Repairs, San Francisco, Cal.—With a tender of \$19,599, the General Engineering and Drydock Company, of San Francisco, Cal., was low bidder for extensive repairs to the Shipping Board steamer West Cadron.

Collier Overhauling, Portsmouth, Va.—The collier Proteus is at the Navy yard for the installation of stowage for 26-foot motor boats, installation of strainer boxes for her bilges and recommendations for stowage of gasoline drums.

Wireless, Etc., San Francisco, Cal.—The lumber carrier George L. Olson, of the Oliver L. Olson firm, was taken to the plant of the General Engineering and Drydock Company to have a wireless outfit and new bronze propeller installed.

Reconditioning Vessel, Oakland, Cal.—The Hanlon Shipyard was low bidder for reconditioning the United States Shipping Board steamer Lake Monona with a bid of \$1,896. Work called for being placed in "spot" condition.

Remodeling Steamer, Newport News, Va.—The contract for remodeling the Old Dominion Transportation steamer Hamilton, recently taken over by the Eastern Steamship Lines, has been awarded Southern Shipyard of Newport News.

Haulon Activities, Oakland, Cal.—The Hanlon Shipbuilding Company is making repairs on the barge Rufus E. Wood, steamer Saginaw, steamer Waimea, Havisdale's barge No. 2, the ship Monahela, and barkentine James Johnson.

Schooners Drydocked, San Francisco, Cal.—The lumber schooner Virginia Olson has been taken to Alameda plant of the Bethlehem Corporation and Avalon has been placed on the company's ways in San Francisco, Cal., for general repairs.

Steamer Overhauled, Buffalo, N. Y.—The steamer C. W. Jacobs, owned by the Hammernill Ship Company and operated out of Erie, was placed in the Buffalo drydock, Ganson street, Buffalo, Mo for overhauling and considerable repairs.

Repairs to Steamer, Savannah, Ga.—The Wilkinson Machine Works was awarded the contract for repairs to the river steamer Hildegard, as a result of grounding, at which time she stripped her crankshaft and dislodged the engine from the bed.

Tug Construction, Buffalo, N. Y.—Work is progressing at the Erie Basin yard on the tug built for the Niagara Ferry Company. This vessel is 58 feet long, 16 feet beam and 7 feet hull. It is nearly all plated and should be completed by July.

Miscellaneous Overhauling, San Francisco, Cal.—The Matson steamer Lurline was placed on the ways of the Bethlehem Shipbuilding Corporation to have her crankshaft out for examination, and to be cleaned, painted and have other miscellaneous work done.

General Repairs, San Francisco, Cal.—The contract for general repairs to the Union Oil Company's tanker Uta-carbon was awarded to the Bethlehem Shipbuilding Corporation, the entire hull to be sandblasted as well as alterations made to her piping system.

Cleaning and Painting, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was awarded the work of cleaning and painting the Norwegian motorship Handicap. The same yard has also awarded the general overhauling of the Matson river Enterprise.

Cargo Steamer to Be Built, Buffalo, N. Y.—Cowles Shipyard Company, 31 St. Clair street, Buffalo, will build a power cargo steamer for the Erie Canal, dimensions to be 105 feet long, 22 feet beam and 12 feet hull. Work will be started in July.

three weeks and it is expected that the vessel will be finished by September. It will be put into service by the Cowles Towing Company, of Buffalo.

Bids for Dories, Staten Island, N. Y.—The Superintendent of Lighthouses, Tompkinsville, Staten Island, N. Y., received sealed proposals on May 28 for the construction and delivery of three fishermen's dories, each to have a length overall of 20 feet and furnished complete.

Schooner Reconditioning, Brooklyn, N. Y.—What is said to be one of the last iron hulled clipper type vessels turned out by the famous shipbuilding firm of R. Steele & Company, the Norwegian schooner Sophie, of 1,753 tons, is to be reconditioned at the Morse Drydock Company's plant.

Tug Overhauled, Buffalo, N. Y.—The tug Globe, owned by the Seaboard Forwarding Company, is being overhauled and repaired at the Erie Basin Shipyard, 114 River street, Buffalo. Some new decks are being built and repairs will be made to the engine, boiler and other machinery.

Drydocking and General Repairs, Oakland, Cal.—The Moore Drydock Company, of Oakland, was awarded the contract for drydocking and general repairs to the United States Shipping Board steamer Jewey, at a price of \$2,224.55. The other bids were: Hanlon's, \$2,286.85, and Bethlehem, \$2,335.85.

Voyage Repairs, Oakland, Cal.—The Moore Drydock Company received the contract for voyage repairs to the Pacific Mail liner President Lincoln, at a price of \$6,464. Alterations of the fire mains from the B deck of the President Lincoln were also awarded to the Moore Company, on a tender of \$50.

Engine Repairs, San Francisco, Cal.—The Bethlehem Shipbuilding Company has been awarded the contract for repairing the port engine of the British motorship Marinula of the Shell Oil Company. This repair job is said to be the largest Diesel engine repair job that has ever been carried out on the Pacific coast.

Vessels Drydocked, Buffalo, N. Y.—The Buffalo Drydock Company, Ganson street, Buffalo, has been awarded the following work: Repairs to Barge Vincent Bird, recently damaged in collision; and the steamer Juniata, of the Great Lakes Transit Company, work of painting and replacing main bearings.

Barges Damaged, Buffalo, N. Y.—The canal barge Isula, owned by the Superior Transportation Company, of Buffalo, was rammed and sunk on May 15 by the steel freighter M. A. Bradley, managed by Harvey H. Brown & Company, Cleveland, Ohio. The incident occurred in the Buffalo River. The canal barge Bird was also damaged.

Sale of Floating Equipment, Brooklyn, N. Y.—Sealed bids were received in the office of the Eastern Surplus Property Control Officer, Army Supply Base, Brooklyn, N. Y., on April 23 for the purchase of floating equipment, including freight and passenger steamers, speed boats, mine yawls, launches, etc.

Reconditioning Steamer, Oakland, Cal.—At the closing of bids for the work of making changes and repairs on the steamer Waimea, formerly the City Tokopa, which was recently purchased by the Los Angeles Steamship Company from the Inter-Island Steam Navigation Company, the Hanlon Shipbuilding Company, of Oakland, Cal., was low.

Shipyard Activities, Buffalo, N. Y.—A second dry steamer, 58 feet long, 8 feet hull and 17 feet beam, has been ordered from the Erie Basin Shipyard, Buffalo, by the Grand Island Ferry Company. Work has been started. The same yard is repairing a boiler in the tug Wing, giving a general overhauling to the tug Globe and placing a new boiler in the tug Clark.

Contract Awarded, San Francisco, Cal.—The contract for the construction of a modern tank steamer, to be equipped with twin Diesel engines driven by an electric generator furnishing 800 horsepower and to be 210 feet long and 40 feet beam, to be kept in service in either the Atlantic or Pacific Ocean, has been awarded to the Bethlehem Shipbuilding Corporation by the Standard Oil Company of California.

Shipyard Activities, Mobile, Ala.—The Alabama Drydock and Shipbuilding Company, Mobile, has received the following contracts: Union Oil Company's steamer Habira for examination, cleaning and painting; Coast Guard cutter Tallapoosa, scrap-iron painting and overhauling; Gulf Refining Company's tug E. L. Russel, rudder repairs; and the

Gulf Refining Company's barge Ohio, cleaning, painting and rudder job.

Voyage Repairs, San Francisco, Cal.—The General Engineering and Drydock Company, San Francisco, was awarded the contract for voyage repairs to the United States army transport Thomas, the bids being as follows: General Engineering, \$1,563; Main Iron Works, \$1,809; Moore's, \$1,832; Columbia Machine Works, \$1,842; Bethlehem, \$2,050; United Engineering, \$2,162; Smith & Scanlon, \$2,445, and Hanlon Shipbuilding Co., \$2,498.

Shipyard Activities, Mobile, Ala.—The Alabama Drydock and Shipbuilding Company was awarded the following contracts: Shipping Board tanker Derbyline, for examination, tail shaft drawn, hull, masts, etc., painted; river steamer Volcano, rudder repairs and engine room work; Shipping Board steamer Portola Plumas (now Pure Oil Company's steamer W. E. Hutton) extensive repairs; and minor repairs to the steamship Jacob Luckenbach.

Steamer Overhauling, Buffalo, N. Y.—The Buffalo Drydock, Ganson street, Buffalo, has placed a new stem and twelve plates on the steamer Harry Yates, recently damaged by ramming a concrete pier in the harbor. The same company has put a new wheel on the steamer Mapleboro, damaged in Lake Erie, by ice, and has been awarded the contract for repairing the steamship Niagara, which broke her wheel and rudder by striking against a bank in the Welland Canal.

Destroyers, Etc., Overhauled, Norfolk, Va.—Five destroyers, Isherwood, Zreck, Lardner, Toucey and Case, are at the Norfolk Navy Yard for overhauling. Another vessel of the division is due shortly, while another division is scheduled to arrive about the middle of May for the same purpose. The minesweepers Contocook, Rail and Robin, and the supply ships Vestal, Vireo and Trogeus have been assigned by the Navy Department to follow to Hampton Roads for repairs also.

Reconditioning, Portsmouth, Va.—The Navy cargo ship Capella, which is reported at the Canal Zone on her trip from the West Coast to the Atlantic, will go to the Navy yard for work which will include investigation as to installation of waterway along the boat deck and moving the after bulkhead of the wardroom passage aft, so as to enlarge the wardroom pantry. There will also be recommendation made for installing suitable davits for dinghy on the poop deck. The pitch of the Capella's propeller will be checked.

Ferry Launched, Pittsburgh, Pa.—The largest boat ever built on the Ohio River, the George H. Walker, was recently launched from the ways of the Dravo Construction Company at Pittsburgh. The new ferry is of steel construction, 340 feet long with 91.6 feet beam, and is for the Gulf Coast Lines to be operated as a ferry between Baton Rouge and Anchorage. It will be propelled by two independently operated side wheels of thirty-one feet diameter. Operation of the boat will be directed from the pilot house by a mechanical telegraph system in place of the usual river system of bells and gongs.

Bids Asked for Motor Tugs, Philadelphia, Pa.—The motor tugs for which the United States Engineer Office, Philadelphia, will open sealed proposals at noon, Eastern Standard time, on June 22, are to have an overall length of 53 feet 3 inches, beam 14 feet 1½ inches and displacement 41 tons. The engines are to be of the multiple cylinder, vertical, two or four stroke cycle, single acting, heavy duty, marine type, capable of operating on kerosene and on fuel oils of not less than 24 degrees Baumé gravity, to be the product of an American manufacturer and of not less than 90 brake horsepower. Two of the tugs are to be delivered at Philadelphia, one at Kewaunee, Wis., and one at Chicago, Ill.

Boiler and Tank Work, Portland, Ore.—Sealed proposals were received by United States Engineer Office, 321 Custom House, Portland, Ore., on May 28, for the carrying out of boiler and tank work on United States dredge Clatsop. Principal work to be done under the specifications consists of furnishing the labor and necessary material and removing two Scotch marine boilers, and in their stead install, ready for operation, two watertube boilers to be furnished by the government; construct and install, ready for operation, two oil tanks about 5 feet diameter by 24 feet long, and two oil tanks about 4 feet by 6 feet by 13 feet; make water tanks, ready for use, out of a portion of the two aft coal bunkers and cut two hatches in the main deck each side of the engine room house, providing a hatch cover for each. Each of the furnaces is to be provided with five Coen mechanical oil burners, the registers and burners to be furnished by the government and installed by the contractor.

SHIPYARDS AND DRYDOCKS

Floating Dock, Vancouver, B. C.—Final arrangements have been made for the construction of the 15,000 ton floating drydock to be built at Vancouver, B. C., for the Wallace Dry Dock Company of that port, constructed from designs prepared by W. T. Donnelly, of 17 Battery place, New York. The dock, of wood pontoon and steel wings, will be able to handle a vessel of 575 feet and will have 98 feet in the clear. It will be built in two sections and will be ready in about six months. The Wallace Dry Dock Company will invest approximately \$1,250,000 in the building project, including besides the dock a 700-foot pier, large machine shop, plate shop, blacksmith shop and power house.

Shipyard to Be Sold, Tampa, Fla.—The largest shipyard in Florida, the Oscar Daniel Shipyard, is to be sold at public auction June 6, 7 and 8, by the Industrial Plants Corporation, of New York. The sale will include all of the machinery, steel, equipment, supplies, ship chandlery, pipe, locomotive, trains, flat cars, rail, etc., located at the yard. The Oscar Daniel Shipyard was built in 1918-1919, at a cost of over \$1,000,000, for the building of steel ships of the 10,000-ton class. Machinery and equipment are of the latest, most modern type. Included in this sale will be offered about 1,000 tons of new steel plates and angles. Persons planning to attend this auction sale should communicate with Frederick R. Shore, of the Industrial Plants Corporation, who has made special arrangements with the Seaboard Air Line Railway for special accommodations for such people.

NEW INCORPORATIONS

The Baltimore Steamship Company has increased its capital from \$550,000 to \$2,150,000.

The Argonne Steamship Company of Manhattan has filed dissolution papers at Albany.

Steamship Terminal Operating Corporation, capital \$100,000, chartered under Delaware laws.

Atlantic Marine & Shipyards Corporation of Wilmington, Del., capital \$100,000, chartered under Delaware laws.

The Cape Steamship Company, capital \$5,000,000, chartered under Delaware laws. Incorporators: A. C. Harvey, J. M. Lee and A. L. Goodman, of Columbus, Ohio.

McGovern Plumb Salvage Corporation, capital \$25,000, chartered in Delaware, to own ships and salvage boats. Incorporators: E. R. Brause and E. Levinson, of New York.

PORT IMPROVEMENTS

Wharf, Sturgeon Falls, Ont.—Department of Public Works, Ottawa, plans new wharf at Sturgeon Falls. \$30,000. K. M. Cameron, acting chief engineer.

Harbor Development, Florida.—Allotment for improvement on river and harbor projects announced by the War Department includes \$15,000 for Charlotte Harbor, Fla.

Wharf, Haileybury, Ont.—The Department of Public Works, Ottawa, plans to rebuild wharf destroyed by fire last year. \$26,400. K. M. Cameron, acting chief engineer.

Docks, North Tonawanda, N. Y.—Tonawanda Iron Works, care American Radiator Company, Elmwood avenue, Buffalo, plans docks along Niagara River. To exceed \$50,000. A. A. Landon, president.

Wharf, Blind River, Ont.—Sealed proposals were received at the office of R. C. Desrochers, Secretary of the Department of Public Works, Ottawa, May 22, for reconstructing superstructure of timber wharf.

Revetment Wall and Dock, Hamilton, Ont.—City Council and Harbor Board plan revetment wall and dock at foot of Ottawa street, concrete and earth fill with 2,000-foot boat slip. \$400,000. W. F. McFaul, city engineer. W. Ainslee, 47½ Main street, E., chairman, Harbor Board.

Contract Awarded, Philadelphia, Pa.—The Department of Wharves, Philadelphia, has awarded the contract for the construction of a steel barge with a capacity of 100,000 gallons to the Clinton Shipbuilding Company.

Dredging Operations, Norfolk, Va.—The Calkins Dredging Company, of Norfolk, has started dredging operations in Paradise Creek just south of the Navy Yard annex. The channel will be given depth to accommodate seagoing vessels.

Paint, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Orleans Court Building, on May 31, for furnishing 1,250 gallons of yellow paint. Requisition SK-1240.

Repairs to Piers and Bulkheads, Hoboken, N. J.—The Robins-Ripley Company has been awarded the contract for repairing all the piers and bulkheads of the United States Lines in Hoboken. This work is already under way and rapidly progressing.

Grain Elevator, Winnipeg, Man.—N. Bawlf Terminal Elevator Company, Grain Exchange Building, awarded the contract for a reinforced-concrete grain elevator, 1,500,000 bushels, to Carter-Halls & Aldinger, Union Bank Building, at a price of \$750,000.

Dikes and Dredging Channel, Brooklyn, N. Y.—Bids were received May 21 by J. H. Delaney, Commissioner of Docks, Pier "A," foot of Battery Place, North River, New York, for dikes and dredging channel between Mill Basin and Paerdegat Basin, Jamaica Bay, Brooklyn, N. Y. Contract 1797.

Wharf Escalators, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans at their office, Suite 200, New Orleans Court Building, until 3 P. M., May 31, for furnishing portable escalators, for use at the Public Cotton Warehouse Wharf. Requisition E. D. 13428.

Creosoted Timber, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, on May 31, for furnishing approximately 85,000 feet (board measure) creosoted timber, and 195 creosoted piles 50 feet long, as per Dock Board specifications. Requisitions ED-13505 and ED-13506.

Reconstructing Shed, New Orleans, La.—The Board of Commissioners of the Port of New Orleans received sealed proposals on May 31 for the reconstruction of the Celeste Street Shed, comprising tearing down and re-erecting riverside portion, raising land side portion, connecting to Market Street Shed and painting. Requisition ED-13470.

Hydraulic Work, Iowa.—Sealed proposals were received at the office of the Secretary, Mississippi River Commission, 1311 International Life Building, St. Louis, Mo., until 11 A. M., May 21, for constructing about 300,000 cubic yards of earthwork by the hydraulic method in the Louisa County Levee District No. 15, Iowa. Further information on application.

Levee Work, Iowa River.—Sealed proposals were received at the office of the Secretary, Mississippi River Commission, 1311 International Life Building, St. Louis, Mo., until 11 A. M., May 21, for constructing about 645,000 cubic yards of earthwork by the hydraulic method in the Iowa River-Flint Creek Levee District No. 16, Iowa. Further information on application.

Contract Awarded, Baltimore, Md.—The foundation dredging contract for the McComas Pier has been let jointly to the Rundel Corporation and the Sanford Brooks Company, of Baltimore. Dredging consisting of 770,000 cubic yards of mud at 19.9 cents per yard; sand and gravel, 550,000 cubic yards at 27.5 cents per yard. The sand and gravel taken from the Patapsco Terminal is to be used as a foundation on the bulkhead line at the McComas Terminal and the mud taken from the McComas Terminal is to be used as fill in small creek abreast of Thomas Cove in the harbor.

GOVERNMENT WORK

Dredging, Green Bay, Wis.—Sealed proposals were received by U. S. Engineer, Milwaukee, Wis., until 3 p. m., May 31, for dredging at Green Bay, Wis. Further information on application.

Retaining Wall and Concrete Culverts, Fergus, Ont.—Wellington Company is having plans prepared for several reinforced-concrete culverts and retain-

ing wall; \$50,000. A. W. Connor, 34 Victoria street, Toronto, engineer.

Dredging, Duck Island, Conn.—Sealed proposals were received by U. S. Engineer, Providence, R. I., until 12 m., eastern standard time, May 31, for dredging in Duck Island Harbor, Conn. Further information on application.

Dock, Milwaukee, Wis.—The Sewerage Commission, 508 Market street, awarded the contract for 1,338-foot pile and concrete dock around west end of sewage disposal plant, to W. W. Whitney, 216 West Water street, at \$138,768.

Motor-Launch Hull, Vicksburg, Miss.—Bids were received by the Mississippi River Commission, Third District, P. O. Box 404, Vicksburg, until 11 a. m., May 22, for furnishing one steel motor-launch hull. Further information on application.

Jetty Construction, Mississippi River.—U. S. Engineer Office, 329 Custom House, New Orleans, received sealed proposals until 9 a. m., June 1, for jetty construction at South Pass, Mississippi River. Further information on application.

Training Wall, Etc., Richmond Harbor, Cal.—Sealed proposals were received by U. S. Engineer Office, San Francisco, Cal., until 11 a. m., June 1, for dredging and building training wall in Richmond Harbor, Cal. Further information on application.

Retaining Walls, Freehold, N. J.—Sealed bids were received until May 16 by the Board of Freeholders, Monmouth County, for reinforced-concrete retaining walls at Bridge W-43 between Avon and Belmar. G. K. Allen, Jr., 60 Broad street, Red Bank, engineer.

Dredging and Pier Removal, Calumet River, Ill.—Sealed proposals will be received at the United States Engineer Office, 537 South Dearborn street, Chicago, Ill., for dredging and pier removal in Calumet Harbor and River, Ill. and Ind. Further information on application.

Dredging, Los Angeles, Cal.—Proposals were received at the office of the U. S. Engineer, Central Building, until May 18, for dredging in Los Angeles Harbor. Area 3—1,270,000 cubic yards with maximum allowable over-depth 36,000 cubic yards; Area 4—610,000 cubic yards, over-depth allowance 20,000 cubic yards; Area 5—\$20,000 cubic yards, over-depth allowance 24,000 cubic yards; Area 6—200,000 cubic yards, over-depth allowance 20,000 cubic yards.

Contract Awarded, New York.—Power Corporation of New York, Northern New York Trust Company Building, Watertown, awarded the contract for 12,500 cubic yards earth and 3,000 cubic yards rock excavation, 8,500 cubic yards of earth embankment, also reinforced-concrete power house and 800-foot concrete dam, 65 feet high, 20,000 cubic yards concrete, at Flat Rock site, on Oswegatchie River, to Burns Brothers & Haley, Inc., Bank Building, Watertown, \$800,000.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The American Marine Congress

THE Marine Congress that is to be held in New York City during American Marine Week deserves and should receive the hearty support of every organization, concern and individual having to do with American ships and shipping. It is the first real attempt that has ever been made in the marine field to bring together not only those who make a living out of the industry but also all commercial, manufacturing and farming organizations, concerns and individuals interested in water transportation.

America will never have a really great merchant marine until the importance of that industry to the welfare and progress of the country is thoroughly understood. In the past a lot of educational work has been done by various organizations; but no attempt has heretofore been made to get everybody around one table for a frank discussion of the subject. It is just that, that the American Marine Association had in mind when it formulated its plans for the Congress in November. It has succeeded in building committees composed of men best qualified to represent the several interests concerned; and the movement has the backing of the Hon. Herbert C. Hoover, Secretary of Commerce, who has been outspoken in his belief that the proposed Congress will do much to effect a better understanding of the necessity for an American merchant marine.

We bespeak for this Congress the support that these industries as a whole can give when once convinced that the purpose is right.

Why Government Ownership?

WHILE the question of Government ownership and operation of Shipping Board vessels had not been determined at the time this issue of MARINE ENGINEERING AND SHIPPING AGE went to press, nevertheless that course was threatened to the extent that a committee of three members of the board had been appointed to formulate a workable plan.

First, let us make it clear that we do not believe in either Government ownership or Government operation as against private ownership and private operation in any industry. The reasons are too well known to warrant discussion here. For results in a field closely parallel to the marine field, we have but to point to the consistent failures in the railway field in all of those countries of the world that have tried it, including our own experience in the last war. President Harding in his speech at Kansas City on June 22 said, on the question of possible Government ownership of railways: "In the present state of the public treasury and of tax burdens, and in the light of recent sad experience with Government management, this is not to be considered. I believe it would be politically, socially and economically disastrous."

With the marine field, however, there is the added and very important difference that while with the railways the question is national, with ships, other than those in coast-wise traffic, it is international. There, successful operation means profitable return cargoes; and ability to get profitable cargoes from foreign countries means a flexible organization capable of securing the business and making rates and changing destinations at a moment's notice—something absolutely impossible under Government ownership, notwithstanding that at least one member of the Shipping Board has stated, in connection with cargo vessels, that the Government would keep surplus ships in various ports ready for instant loading and would quote rates sufficiently low to meet any competitor.

Now, what is the Government's plan insofar as it has progressed? The Shipping Board has seven members; and at the moment there are seven different opinions as to the course to be followed. Out of the confusion of opinions looms a scheme involving the formation of some eighteen different companies. If eighteen "companies" means that many corporate entities, the present loss of some fifty millions of dollars a year would soon be multiplied several times and in fact would probably be multiplied at least twice under any plan that may be evolved, because experience has

taught us that no Government can operate any business at anything other than an imaginary profit; that if the loss is now fifty millions of dollars a year with a number of ships being operated by private corporations, the loss under full Government operation would be far greater on a like accounting basis.

But if the Shipping Board is determined to go ahead, why the very considerable additional executive overhead and red-tape incident to eighteen separate corporations? Why the added burden on the taxpayer when it is possible by concentration of routes and a departmental organization to carry on with one corporation? There is plenty of precedent in the business world for the manipulation of numerous units by one corporate body with one board of directors and one executive head, the scattered units being but departments of the whole.

We have said that within the Shipping Board there are seven different opinions as to how the threat of Government ownership and operation should be carried out. There is a still further complication than that for substantially all of them either do not favor Government ownership or are opposed to that course. This is especially significant in view of the fact that all are political appointees and might be expected to line up on the other side of the fence. In any event, because of those differences and the attitude of the country generally toward Government ownership and operation; because of the slogan of the present administration—"less Government in business, more business in Government"—which has been so well reflected in the work of some departments at Washington, especially the Department of Commerce; and because of the very serious effect Government ownership and operation on the seas will have on the American merchant marine as a whole, why not a renewed effort to find a way out of the present dilemma?

First, scrap all ships which cannot possibly be sold because unfit for profitable operation. They are in any event as much of a menace to the progress of the American merchant marine as are derelicts to navigation. Then sell all of the others to private owners either after first installing Diesel engines and in other ways refitting for competitive business such of the vessels as would be amenable to that treatment, or else authorizing the purchaser to do so, the job to be financed by the Government. With that determined, the question of price only would be left; and while not an easy nut to crack, it is far from being insurmountable. Some routes and vessels could be sold outright at predetermined figures. As to the others, an equitable course should not and would not be hard, if approached from both sides in the right spirit. The Government could well afford to make contracts for the operation of routes and ships on a specified income or interest and time payment basis, the ultimate purchase price to be determined by the results from operation for a given period. Perhaps prospective purchasers should be asked to pay a fixed minimum in cash at the start, the excess to be determined in the manner suggested. At any rate, the result would be the elimination of a Government expense of at least fifty millions of dollars a year and the return to the Treasury of some part of the cost of the ships, at the same time giving new life and increased determination to the American merchant marine as a whole

and a new hope to that great industry which has to do with building, repairing and equipping ships and which is now suffering unnecessarily because of the present chaos, in which the Government is playing so important a part.

"Squandering Good Will Abroad"

ONE of the best arguments for an American merchant marine is that our own ships would assure our farmers and manufacturers of a regular and reliable source of delivery of their products to foreign markets without transshipment. But such is the perversity of this God-favored nation, that the minute anything approaching boom times appears, the producers forget that foreign trade is absolutely essential "to level out the valleys of periodic depression in business cycles and to keep their factories and farms steadily employed."

In a recent article Mr. Julius Klein, director of the Bureau of Foreign and Domestic Commerce said, "an old abuse, so costly in the past to American prestige abroad, is again creeping into our export trade. Under the allurements of domestic boom conditions many of our manufacturers are showing increasing apathy to the legitimate requests and orders of foreign contacts whose patronage they so carefully solicited during the past few years. The sound policy of definite allotments for export is being ignored in far too many cases. Unless this disloyalty to firmly establish foreign contacts is promptly overcome, American commercial prestige and good will abroad are likely to suffer serious damage."

According to Mr. Klein, "a number of British firms who are representatives of American manufacturing exporters are sick and tired of the foreign trade flirtations of their American connections whose export interest shifts with every vibration of domestic demands." It takes years of patience and hard work to build up a foreign business and, if the results of all the efforts that have been made to obtain an outlet for our surplusage are to be thrown away because our manufacturers are temporarily having trouble in supplying the domestic demand, then it is a situation that affects not only the merchant marine but every citizen in the country. This is a matter that should receive the serious attention of our commercial organizations.

Insurance Tax Vetoed

EFFECTIVE pressure was brought to bear upon Governor Smith by powerful insurance brokerage interests who urged that the Sheridan Act would prove a serious injustice to shippers in this country who find it impossible to secure full coverage here, and the Governor vetoed the bill. This was Senate bill 1690, printed number 2289, entitled "An act to amend the tax law and to impose a tax upon residents of the State and upon persons transacting business therein, insured against loss of property by insurers not authorized to transact business in the State." In his memorandum accompanying the veto the Governor gave, as his reasons for withholding approval, a belief that when New York companies are unable to write the insurance there should be no penalty attaching to the insured for seeking protection to his property elsewhere. It was brought out at

the hearing that when the United American Line recently sought four million dollars' coverage on specie shipped abroad it was unable to secure more than a small portion of the insurance in New York State. Under the provisions of the proposed bill a tax would run to the insured of 25 percent on the insurance written with companies not authorized to transact business in this State. "This," said the Governor, "is not the time to handicap men who are endeavoring to build up an American merchant marine; nor is it the time to add to the cost of doing business in this State, and particularly at the Port of New York."

Grain Bulk Carriers

DURING the last six months no less than twelve Italian steamers have been lost in the grain bulk carrying trade. Underwriters are trying to find out whether this series of disasters is attributable to the type of vessels or to their nationality. Once grain starts to shift, unless the vessel is small enough to admit of manual labor correcting the situation, the case is next to hopeless. A list at once begins and the grain flows like water to increase it. Foundering is almost certain to result. And there is subsequent trouble over the insurance, because the reason for the disaster did not lie with a peril of the sea but in the inherent nature of the cargo.

Combined Riveting and Welding

IN converting the battleship *Kearsarge* into a seagoing crane-ship with a lifting capacity of 250 tons, the whole ship structure had to be materially reinforced in order to take care of the stresses imposed by the presence of the crane and the possible loads that might be placed on her decks. As pointed out in a full description of this crane-ship appearing in the June issue of *Mechanical Engineering*, the official organ of the American Society of Mechanical Engineers, it was even thought necessary to reinforce the riveted joints in some of the strength members by welding. So the main deck, which is composed of three thicknesses of plating, was, in addition to its riveted connections, electrically butt welded throughout the top strake thus making that member practically one piece of metal. Likewise, it is stated that it was found difficult to select angle irons for connecting the strength bulkheads to the under side of the deck that would have sufficient metal left after the necessary rivet holes had been drilled. It was decided that this problem could be solved by welding the toes of the double bounding angles to the bulkheads for the purpose of taking a large portion of the shear stress off the rivets.

The performance of this crane-ship will be watched with interest for many reasons. It is the only sea-going crane-ship and, at the same time, the largest floating crane in existence. It has already actually lifted 312 tons and may be called upon to lift an even greater weight. The size of the structure has called for a design that exceeds well tested limits. But has it in dealing with stresses of unprecedented magnitude solved the problem of the most efficient joint? In the condition where there is not enough metal left in a plate, or enough plate and not enough rivets be solved by

additional welding? Will a combination of riveting and welding work in unison or will the weld which unites the metal in one piece take the entire load and the elastic limit of the joint be reached before the rivets begin to work? If riveting can not be depended upon for such a connection why not make an entirely welded joint?

The Hull Slump

UNDERWRITERS have had ample opportunity for reviewing the unusual conditions of the past two years, and they are now in position to reflect intelligently upon the circumstances that have militated so seriously against them in an attempt to secure a modicum of profit in writing hulls. The war caused the first great upset, but this was scarcely worse than the astonishing boom in shipping and its subsequent slump. An outstanding feature of underwriting in this period has been the enormous loss of money paid out for "return premiums." This was occasioned by the violent fluctuation in shipping values, which necessitated rearrangements in insurances, sometimes repeatedly during the year. Policies were frequently cancelled after only a month or so had run off, the premium for the balance of the twelve months being returned, generally with a "short period" rate adjustment amounting to 20 percent in reduction. These insurances would be renewed, but always on a substantially reduced valuation. In many instances the underwriters returned more premium for the unexpired period of the old policy than they received for the twelve months of the new.

A North Pole Risk

NOW and again the underwriter is called upon to extend his protection to adventures that tax his ingenuity as regards an approximation of the measurement of hazards involved. But to the experienced insurer there is nothing that can not be written, and with a fighting chance at a profit. Thus, there has been recently placed in the New York market the insurance on the yacht *Bowdoin* which Dr. Donald B. MacMillan is to use on his projected trip to the North Pole. The value of the vessel is \$30,000, and as she was built expressly for Arctic work it is likely that the Doctor is not far from the mark in esteeming her the strongest little craft in the world. The voyage is planned to run from Wiscasset, Me., along the Labrador coast and thence northeast to Greenland, following the Greenland coast northward for a wintering in Ellesmere Land. That is where the underwriter's worries begin—for "wintering" in the Arctic means being frozen in. There the *Bowdoin* will lie, snug and tight, serving as a headquarters while the expedition is pushed northward over the ice.

What do they expect the underwriters to do? Insure the vessel for the round trip, including the period of being frozen in, against the risks of total and/or constructive total loss and general average and salvage charges. In the judgment of the insurers this was scarcely an undertaking exactly within their sphere; but as it was an American enterprise and for laudable purpose, they did not hesitate to participate. The entire risk was placed in the New York market at a rate of 12½ percent.

Officials and Guests on the L

Leviathan on Trial Trip Breaks World Records

**687 Miles in 25 Hours at Average Speed of
27.48 Knots — 28.04 Knots in One Hour**

By Harold F. Lane*

ALL established world records for sustained speed by an ocean liner, as well as the speed record for one hour, were broken by the *Leviathan*, reconditioned at the Newport News Shipbuilding and Dry Dock Company on the return run of its trial trip, made from Boston to Abaco in the Bahamas and back to New York, June 19 to 24, under the command of Captain Herbert Hartley, and under the supervision of Gibbs Brothers, Inc., who have had general charge of the reconditioning and the trial trip for the Shipping Board.

After leaving Boston under somewhat of a cloud of ignorant and partisan or malicious criticism and, it is reported, with some fear on the part of Shipping Board officials that an effort would be made at the last minute to stop the trip by injunction as an unnecessary "joy ride," the big ship came back with the broom at its masthead and the passengers filled with new enthusiasm for a successful American merchant marine which the enormous amount of publicity the trip received helped to spread among the public.

During the 25-hour period from 7:17 A. M. on June 22 to 8:17 A. M. on June 23 the *Leviathan* made a distance of 687 nautical miles, from Jupiter Light, off the coast of Florida, to a point approximately off Norfolk, Va., at an average speed of 27.48 knots. For the first hour of that period the average speed was 28.04 knots and for 6 hours of the time the average was over 28 knots, while for 12 hours the average was 27.94 knots.

The distance run for the 25-hour period is 11 miles more than the best record ever made by an ocean liner, that of

the *Mauretania*, which, on January 25 and 26, 1911, made 676 miles in 25 hours at an average speed of 27.04 knots. The highest speed made by the *Leviathan* for an hour also exceeds the fastest speed of the *Mauretania* by approximately half a knot.

CREDIT GIVEN TO PRESIDENT HARDING'S ENCOURAGEMENT

Albert D. Lasker, who retired as chairman of the Shipping Board on the day of the start of the trial trip, sent a radiogram to President Harding informing him of the accomplishment immediately upon the announcement of the record made by the *Leviathan*, which, he said, was reconditioned through the constant encouragement the President has always given the merchant marine. "Thus, through its first big ship, in its first trial run, America has the largest, the finest and the fastest ship in the world," Mr. Lasker said. "an inspiring premier ship to our merchant marine. May this performance enthuse our people as it should and be some return to you for your constant interest in and enthusiasm for America on the seas. It is an historic tribute to the genius of those who redesigned and rebuilt the *Leviathan* champion of the seas, her officers and crew."

ROUTE OF THE TRIAL TRIP

The trial trip was from Boston to Abaco Island, then through Providence Channel and northward in the regular northbound steamer track, via Jupiter Light and Diamond Shoals to New York, a total of 2,209 miles.

On June 18 the ship was taken, partly under tow and partly under its own power, to a point just outside Boston Harbor where the start was made at 3:20 P. M. on June 19. From Boston Light Vessel anchorage it was the intention

* Our Washington correspondent.

ing Her Trial Trip, June 19 to 24

to maintain the engines at approximately 150 revolutions per minute for a 12-hour period but early in the evening an unusually dense fog set in which remained throughout the night and it was necessary to reduce the speed from 18

to 8 or 9 knots. On June 20 and 21 the revolutions were gradually increased for 10 and 12-hour periods to 160, 170, 175 and 180 per minute and the speed increased to about $23\frac{1}{2}$ knots. From noon of June 20 to noon of June 21 the

J. R. Irwin, First Radio Operator of the Leviathan, Who During the Trial Trip Handled Nearly 7,000 Words in 6½ Hours Without Relief

average speed was 22.1 knots and the distance covered was 530 miles. Abaco Light was passed about midnight on June 21 and the passage through Providence channel made during the night.

The high-speed test was begun when Jupiter Light was passed at 7:17 and on June 22 when the revolutions were increased to the maximum and shortly after 10:00 A. M., a bulletin signed by Staff Commander H. C. Fish announced that up to that time the ship had made 75.7 miles at an average speed of 28.04 knots.

At noon of June 22 the distance from Jupiter was 132 miles, the average speed was still 28.04 knots and the ship was approximately off Daytona, Fla., having made 590 miles in the 24 hours. Succeeding bulletins issued by Staff Commander Fish or Captain Hartley gave the distances and average speed from Jupiter as follows:

2:00 P. M.	188 miles	28 knots
4:00 P. M.	243 miles	28 knots
6:00 P. M.	300.6 miles	28.1 knots
8:00 P. M.	355 miles	27.94 knots
10:00 P. M.	411 miles	27.96 knots
8:17 A. M.	687 miles	27.48 knots
12:00 M. June 22 to 12:00 M. June 23, 595 miles, 25.2 knots		

LOG OF THE RECORD-BREAKING TRIP

Later there was printed on board and issued to the guests the abstract of the log printed on this page.

Only a few minutes after the completion of the 25-hour run, the ship then being off the Chesapeake Capes, a fog set in which made it necessary to run very slowly until after noon and at one time to stop entirely upon a signal from another vessel close ahead. The fog continued throughout

TRIAL TRIP JUNE 18TH TO JUNE 24TH, 1923

Date	Hour	Lat. N.	Long. W.	Miles	Remarks
June 18	12.58 A.M.				Left Commonwealth Dry Dock.
	3.59 P.M.				Anchored off Boston Light Vessel.
June 19	3.20 P.M.				Hove up anchor and proceeded to sea.
June 20	12.00 noon	38.09	70.26	300	Dense fog throughout night. Steamed at reduced speed. Smooth sea. Ave. speed 14.6.
June 21	12.00 noon	30.08	74.50	530	Fine and clear weather. Small sea. Average speed 22.1.
June 22	12.00 noon	29.09	79.40	590	Fine and clear weather. Smooth sea. Average speed 24.58.
June 23	12.00 noon	37.31	74.08	595	Morning watch ran into dense fog. Steamed at reduced speed. Average speed 25.2.
June 24	4.47 A.M.			194	Arrived Ambrose Light vessel in thick fog. Steamed at reduced speed. Ave. speed 11.6.

Total distance 2,209

Jupiter Light House abeam 7.17 A. M., June 22d. Then followed the regular north-bound steamship track to Diamond Shoal Light vessel, arriving there 3.39 A. M., June 23d. Distance, 570 miles. Ship making an average speed of 27.99 knots.

From Jupiter Light House to lat. 36.52 N., long. 74.21 W., a distance of 687 miles, was made in 25 hours, making an average speed of 27.48 knots.

During the first hour of the trial run from Jupiter Light, the average speed of the vessel was 28.04 knots, and for a six hour period the average speed of the vessel was 28 knots.

the day and night and until late in the afternoon of Sunday, June 25, making it necessary to anchor off Ambrose light until nearly 5:00 P. M. The dock was reached about 8:15 after the ship had been accorded a noisy welcome by the whistles of every craft in the harbor.

On the original German trial trips the *Vaterland*, as the

ship was then called, had made a maximum speed of 25.84 knots burning coal.

The trial trip was made with a crew of 1,135 and with 456 passengers, including Mr. Lasker and Commissioners Thompson, Plummer and O'Connor of the Shipping Board. President J. B. Smull and Vice-presidents W. J. Love and J. F. Sheedy of the Emergency Fleet Corporation, President Homer Ferguson and officials and experts of the Newport News Shipbuilding & Drydock Company, and the other invited guests. The guests included a number of members of Congress, prominent shipping and railroad and business men and newspaper men.

TEST MADE UNDER ARDUOUS CONDITIONS

While the speed record was assisted to some extent by the Gulf Stream and a calm sea as the English record was by the still stronger current of the tides in the English channel, the test was made under most severe conditions in many respects, according to Mr. Gibbs, because of the effect of the high temperature of the semi-tropical seawater on the condensing apparatus. It is important to have as cold circulating water as possible. The circulating water at the time of the high speed run was at a temperature of about 84 degrees Fahrenheit as against about 60 degrees normally found in more northern waters where trials are usually run. As the higher temperature operates against obtaining the highest vacuum in the condensers, the performance under these conditions was considered remarkable. During the time the ship was in colder waters fog conditions prevailed for much of the time. When the ship was built the Germans took it to the North Sea for a test and our Navy trials are usually conducted off Rockland, Me. The warm latitude also afforded an excellent test of the ventilating apparatus.

W. F. Gibbs, who has devoted practically the past four

years to planning and carrying out the work of reconditioning the *Leviathan*, as well as the other technical men aboard who had participated in the redesigning, and members of the Shipping Board, were highly elated with the performance of the fuel oil plant and other new equipment, which in many respects exceeded their expectations. It was stated that no new ship of the largest type had ever been subjected to as severe conditions on a trial trip and yet the fuel consumption was less and the power generated, the revolutions per minute and the vacuum attained were greater than had been expected. While official figures as to the engine performance were not given out it was unofficially reported that the horsepower generated was approximately 84,000 and the revolutions per minute 184.

The ship is expected in service to make an average of about 23½ knots, leaving New York on Saturday at noon and arriving at Cherbourg Friday morning and Southampton Friday afternoon, but it was demonstrated that a more than ample reserve margin of power and speed is available for making better time if necessary. Not a pipe leak was found in the entire trip which would require the services of a pipe fitter and it was stated that no more work would be required after the arrival in New York than after an ordinary return trip. The power generated was greater than that for which the ship was originally designed and 25 percent greater than it had ever developed before, without strain. Also the guests were highly pleased with the service and appointments of the vessel.

PERFORMANCE HIGHLY SATISFACTORY TO OFFICIALS

The performance of the ship and the records made were the occasion of many felicitations among the officials and in the evening of June 22 a meeting was held in the first class social room at which moving pictures of the *Leviathan*

(Continued on page 412)

The Leviathan Receiving Her Finishing Touches in Commonwealth Dry Dock, South Boston, Mass., Prior to Her Trial Trip

S.S. "LEVIATHAN"

RECONDITIONED 1923

BY THE NEWPORT NEWS SHIPBUILDING AND DRYDOCK COMPANY

NEWPORT NEWS, VIRGINIA.

HULL No 264

PLANS PREPARED AND WORK SUPERVISED FOR
THE UNITED STATES SHIPPING BOARD
BY GIBBS BROTHERS, INCORPORATED
NEW YORK.

"OUT there," in the Golden West, they have the habit of speaking in superlatives, when describing the natural advantages of the country, as the highest mountains, the finest climate and the grandest scenery. While we in the East are perhaps not so favored by the magnificent works of God nevertheless we can point with pride to many of the greatest achievements of man, namely, the tallest buildings, the longest bridges, and now, thanks to the Newport News Shipbuilding and Dry Dock Company, the largest, the safest and perhaps the fastest ocean liner in the world.

It is true that this great ship was originally built in Hamburg, Germany, but she has, with the exception of the outside shell, been practically reconstructed in this country. Extensive structural changes have been made in the hull for the purpose of increasing her strength and safety. It may now be stated that she will still stay afloat even if any three adjacent hold compartments are flooded. She has been converted from a coal to an oil burner. The machinery has been overhauled and repaired. All quarters below the D weather deck are new construction. All passenger accommodations and crew's quarters have been reconditioned, decorated and furnished. Complete new galley and pantry equipment has been provided. An improved electric wiring system, new steam heating, plumbing, ventilation and drainage systems have been installed. Access holes have been constructed in the shell in the way of the fuel oil tanks so that oil sludge and residue may be easily removed when the vessel is in dry dock, new bilge keels have been fitted and, in fact, all the latest and improved fittings and equipment of American manufacture that will add to the safety and comfort of the passengers and vessel have been furnished by hundreds of sub-contractors.

PRINCIPAL CHARACTERISTICS

Length, overall	950 feet 7 inches
Length, between perpendiculars	928 feet 5 inches
Breadth, molded	100 feet 0 inches
Depth, molded to D deck	70 feet 4 1/4 inches
Block coefficient	0.625
Class, American Bureau of Shipping.	
Displacement	66,800 tons

Gross tonnage	59,957 tons
Net tonnage, about	28,000 tons
Boilers, modified Yarrow watertube	46
Engines, Parsons direct connected reaction turbines.	
Propellers	4
Officers and crew	1,115
First class passengers	976
Second class passengers	542
Third class passengers	944
Fourth class passengers	936
Decks, steel, extending full length	5
Decks, on superstructure	4

PLANS AND SPECIFICATIONS

Before work could be started on the *Leviathan* it was necessary to draw up a complete set of plans and specifications. Her original plans were not available and practically all of her interior had been removed to provide sufficient berthing space for from 11,000 to 12,000 troops. This work and the subsequent supervision of her reconditioning was performed by Gibbs Brothers, Inc., New York. As an indication of the thoroughness of their work it may be stated that the plans published in our issue of last November are accurate today.

BRIDGE DECK

The navigating bridge, located on the forward end of the bridge deck, is shown in one of the accompanying illustrations. It will be noted that it is protected from the weather on the forward side by a bulkhead extending the full width of the deck house and amply supplied with port holes. The sides of the protected area may also be closed by a removable partition. The bridge wings which extend slightly beyond the sides of the vessel are open. A pelorus actuated by the master gyro compass is located on each wing from which azimuths and bearings may be taken. The control for a 36-inch Sperry searchlight is located on the starboard wing.

Inside the protected area are installed the usual magnetic compass and steering wheel, a repeating Sperry gyro compass, engine room telegraphs, telegraphs for conveying instructions for handling the anchors and spring lines, rudder position indicators, pneumatic gages for indicating the for-

ward, mean and aft drafts and positive and automatic controls for the whistles and fog sirens. On the port side in an inclosed space is the receiving apparatus for the submarine signal system.

WHEEL HOUSE

In the wheel house just aft of the navigating bridge are many more instruments including a 30-day gyro course recorder, a Forbes log for determining both the speed and distance traveled, the watertight door diagram and hydraulic control and a magnetic and a gyro repeater compass. The vessel is provided with two master Sperry gyro compasses located in a special compartment below. They actuate five repeaters—three on the bridge, one in the wheel house and one in the captain's bedroom.

FIRE ALARM STATION

Aft of the wheel house in the officers' quarters is located one of the smallest but most important rooms on the ship,

Fire Alarm Station on the Bridge Deck

called the fire alarm station. In this room, which measures only 4 feet by 9 feet, are housed all the terminals of the different fire detecting and alarm devices. As shown in one of the accompanying illustrations, a man is always on duty here to assure immediate action in case of fire.

Just inside the door is a cabinet with a glass front in the upper portion, known as the "Rich System," for detecting and extinguishing fires. Inside the glass of this cabinet are the terminals of some twenty-two tubes. These tubes lead down to the compartments in the lower part of the ship or hold of the vessel, such as store rooms, baggage rooms, cargo spaces, oil room, lamp room, paint room, refrigerators, etc., which are not frequented by members of the crew. Directly above the cabinet is a suction fan which is constantly in motion, sucking up air from the different compartments. If at any time the slightest bit of smoke occurs in any one of these compartments, it will in the course

of only a few seconds find its way to the tube, come up to the station and show in the cabinet.

There are also, in connection with this system, two other cabinets situated on one of the lower decks, where, in case a fire is discovered in any compartment, by lifting a lever the upper part of the tube may be closed and the smoke shut off. Then by opening a valve, steam at a pressure of 240 pounds per square inch is sent down into the compartment filling it with steam and smothering the fire without anyone going near it. However, before turning on the steam it would be advisable to ascertain whether any one happened to be in the compartment, as a puff of smoke from a cigarette will show in the cabinet.

AUTOMATIC ALARM SYSTEM IN LIVING SPACES

Another device for detecting and locating a fire is known as the "Aero Automatic Fire Alarm." In each of the guest rooms, crew quarters, offices, galleys, pantries, etc., there is a rosette located on the ceiling which appears to be of wire but which in reality is a fine hollow tube made of copper. A sudden rise of temperature from any cause in any of these rooms for a duration of 30 seconds will cause the air in the tube to expand and press against a delicate sensitive diaphragm, which, in turn, will make an electric contact that will register the location on the annunciator in the fire alarm station. If, at any time, through accident or other cause, the electric current should be cut off from the system, the attention of the attendant is immediately attracted by a buzzer operated automatically when the current ceases. He will then notify the electrician by 'phone who will locate the trouble.

MANUAL ALARM SYSTEM

Scattered throughout the ship are a number of small fire alarm boxes with a glass front having a red light burning on top. These are known as and are in connection with the "Manual Fire Alarm System." There are forty-five of these boxes, each one numbered, and the members of the crew are required to know the location of these boxes according to their respective numbers. This system is practically the same as that used by the city fire departments, it being only necessary to break the glass to send in an alarm. The breaking of the glass relieves a plunger which forms an electrical contact and registers on the Cory annunciator located in the fire alarm station. It also rings a bell in the station and shows, by a red light, the number of the box in which the glass has been broken. Should one of the red lights on top of a fire box burn out or become loose in the socket; or should a wire become disconnected or broken, or, in fact, if anything should happen to break the current on any of these manual alarm circuits, a green light on the annunciator board will indicate the number of the circuit which is broken and a buzzer will attract the attention of the attendant. The electrician will then be notified of the trouble which must be immediately rectified.

As soon as an alarm comes into the station from any of these systems the attendant steps into the wheel house, which is only a few feet away, notifies the officer on watch and sounds the alarm on the bells which are located throughout the crew's quarters and in the engine room. By sounding the number of the alarm box nearest the fire, the crew are immediately apprised of the proper place to assemble. All of this is done so quickly that it would be impossible for a fire to make any headway. As soon as an alarm is sounded, the engineers on duty stand by the pumps which supply the pressure to the fire main and increase this pressure as needed.

A pressure is maintained at all times on the fire main and a pressure gage indicating it is located in the fire alarm station. If the pressure goes down, the engine room is notified and they immediately attend to it. So, there is never a time that water will not flow from every hydrant.

S. S. Leviathan, Flagship of the American Merchant Marine, Ready for Service

FIRE PROTECTION IN THE BOILER ROOMS

With the conversion of the vessel from coal to oil burning it became necessary to provide the utmost protection against the fire hazard involved in the handling, storage and burning of fuel oil. For this purpose a very complete Fire-foam fire extinguishing system was installed by Charles Cory and Son, Inc., New York, designers and installation engineers of the system.

A DECK

The first class smoking room is located at the forward end of the *A* deck directly under the officers' quarters. It is one of the pleasantest rooms on the ship as the forward end of the room is practically all windows that give an unobstructed view ahead. It is paneled in light fumed oak and furnished with leather and tapestry upholstered furniture. With its spacious alcoves and artificial fireplace it should be a comfortable place to while away the time.

The most of the space on this deck is devoted to the upper portion of the public rooms but amidships there is located the first class gymnasium equipped with various devices for keeping oneself fit on the voyage. At the extreme left end of the deck house is the galley of the Ritz-Carlton café, an illustration of which accompanies this article. The galley is equipped with electric ranges, electric bake oven, electric broiler, steam soup kettles, electric meat chopper and grinder, etc., and alongside of it is a room containing an electric ice-cream freezer and an electric griddle.

On the port side forward of the galley is a print shop fitted with three presses, a linotype machine, etc. There is a flower

store on the starboard after end of this deck and a dog kennel on the port side.

A deck may also be called the boat deck although a number of boats are located on *C* deck. There are seventy lifeboats, two of which are motorboats. There are also two work boats. The motorboats are specially designed by the Gibbs Brothers and are capable of towing all the lifeboats at once. They are equipped with an oil engine and a radio.

The lifeboats are nested in groups of three and are served by Welin quadrant davits. These davits can be worked in three ways, namely: By a crank attached to the davits, by levers attached to winches through wire rope leads or by electric motors through the winches and rope leads. A Jacobs ladder is stowed between each nest of boats. Lifeboats Nos. 1 to 12 are stowed on the forward island, 13 to 48 on this deck and 49 to 70 on *C* deck, even numbers being on the port side and odd numbers on the starboard.

B DECK

B deck is given up almost entirely to public rooms which are practically en suite. Many of them extend two deck heights and are so large that they give the appearance of being in a large hotel rather than in a steamship.

Forward on this deck is the first class library, the walls of which are finished in Nile green, which are lightened by a white ceiling. Along the forward side of the room are well stocked bookshelves and on the after side is a portrait of President Harding by Howard Chandler Christy. Easy chairs, writing desks and a carpeted floor provide a comfortable and quiet place for either reading or study.

Quarter Stern View of the Leviathan

Aft of the library comes the first class social hall, which may also be used for a ballroom or theater. It is finished in oak and contains several very large oil paintings. Over the center of the room is a large glass dome which is shown in one of the illustrations. At night the dome is electrically lighted and this is supplemented by reflected lights on top of the oak cornice as well as by numerous lights in brackets along the sides of the walls. The stage at the forward end of the hall is finished in oak and has on it a beautiful oak piano. The illustrations probably give a better idea of this room than can be given by a description.

Aft of the social hall is the grand foyer. It will be noted in one of the illustrations that was taken in this foyer looking forward into the social hall. Passing aft from the foyer one enters what is really two large rooms in one, namely: the palm court or winter garden, with its palm trees and fountains, and the Ritz-Carlton café, where meals are served à la carte. The walls of the palm court are finished in green lattice work with the chairs and tables painted to match. Great tall columns and the rich mahogany finish of the Ritz-Carlton restaurant aft of it are features of exceptional decorative interest.

Still farther aft on *B* deck in a space formerly used as a washroom is a charming tea room finished in Queen Anne style, in oak with color prints on the walls.

THE PROMENADE

Around the entire deck is a very spacious promenade, the use of which is shown in one of the illustrations. The forward part is inclosed with balanced glass windows, which may be opened or closed according to the weather. There

are three expansion joints in this promenade, which of course, extend from one side of the superstructure to the other.

C DECK

On *C* deck the space outside of the promenade is taken up by staterooms, some of which are in suites and others single rooms, both with and without baths. There are two premier suites, one starboard and the other port, which command \$5,000 a passage. These suites contain two bedrooms, a breakfast room, a sun parlor, a drawing room, which may be turned into a bedroom, a kitchenette and three bathrooms. The bedrooms are furnished with twin beds, reading lamps, dressing tables, washstand, davenport, special ventilation through a panel above the beds and many other features.

There are several more suites both on this deck and the deck below containing bedrooms, parlor, bath and trunk room, and, if desired, additional bedrooms may be connected. Typical single staterooms, as shown in one of the illustrations, are paneled in different kinds of wood and are furnished with twin beds, davenport, chairs, reading lamps, dressing tables, hot and cold running water, etc.

On the after end of *C* deck are some exceptionally fine second class staterooms and a veranda.

D DECK

The midship and forward portions of *D* deck are devoted to first class accommodations and the after part to second class public rooms consisting of a smoking room, foyer and social hall, all of which are equivalent in style and comfort to the first class quarters on many ships. The second class smoking room is finished in mahogany with leather uphol-

stered chairs. The social hall is done in white and is fitted with piano, carpets, bookcase and varied colored upholstery.

E DECK

As on *D* deck, the midship and forward portions are devoted to first class accommodations. The engineers' quarters and second class accommodations follow aft and the third class dining room is located still further aft.

F DECK

Fourth class quarters are located on the forward end of this deck followed by first class accommodations and the main dining saloon. Then come the first and second class galleys, the second class dining saloon and third class quarters.

The main dining saloon, which reaches clear across the ship, extends two deck heights in the middle portion. It is

signers had placed aboard the vessel electric bake ovens sufficient for the capacity of the entire vessel, both bread and pastry, and there were a number of other devices such as toasters and broilers used in the a la carte service in the Ritz-Carlton dining and tea room.

Under these conditions and with the elimination of a considerable amount of stateroom heating by electricity, it was found there would be available a fair excess of generator capacity which could be applied for the purpose of electric cooking.

The proposition was divided into three parts: First, all the bakery equipment, which was found to be rather inferior, was to be replaced with modern American design. This consisted of two 25-kilowatt, electric bread baking ovens for the first and second class bakery; one 25-kilowatt oven for the fourth class and crew, and two 9-kilowatt pastry

Main First Class Dining Room

surrounded by a gallery bordered by tall columns. The room is done in white and has a large painted dome which is surrounded by lights over the center. The illustration of this room shows the tables with their dark blue covers and individual lights.

THE SWIMMING POOL

The swimming pool on the deck below, as shown in one of the illustrations, is on the old Roman order. It is not only large in area but also extends two deck heights. A feature of the finish of this room is the stucco work on the walls, which was put on by the Marine Decking and Supply Company. Around the rooms are numerous dressing rooms, a rest room and a room for special baths of electric light and water.

ELECTRIC GALLEY EQUIPMENT

The officials who had charge of the reconditioning of the *Leviathan*, had, as a basis, the fact that the German de-

ovens, one for the first and second class and one in the Ritz-Carlton galley. Second, it was desired to use considerable electric heating for serving devices in pantries and dining room service. This service consists of a two-burner heating plate, and rectangular griddles for the preparation of hot cakes, toast, eggs, etc., without the expense of having this type of work done in the main kitchen. There are on board this vessel about five of these griddles and seven of the hot plates located in the various pantries and serving rooms, as mentioned.

Another important part of this service is in the main dining room where the serving tables, from which the food is distributed by the waiters, are equipped with electrically heated tops of the right temperature so that the food can be kept at the proper heat until it is served. In a large dining room where the distance from the serving pantries is very great, this type of device will be of great help. The amount of electric heat taken is very low, about 150 watts per table,

Glass Dome Over First Class Social Hall

and it is only necessary to provide outlet receptacles on the floors or pantries so that these tables may be plugged in like an ordinary portable lamp. In all there are forty of these tables.

The third part of the electrification was to install as many electric galley ranges in place of the original coal burning equipment as the capacity of the electrical generators would permit. The most difficult place to handle coal and ashes is in the Ritz-Carlton galley on *B* deck, and the electrical capacity was available to completely equip this galley with six 4-foot electrical hotel type sections, together with two broilers and the small bake oven, previously mentioned.

The rest of the galleys are coal burning with the exception of one oil-burning range in the crew's galley.

BAKE OVENS

The electric bake oven was among the first electric cooking appliances to be installed on shipboard. Space limitations, developments and the desire for a bakery location that would exclude the use of fuel ovens has promoted the use of electrical equipment. These ovens are of the so-called deck type, having three horizontal tile backs placed one above the other which are heated by independently controlled heating units placed above and below the decks so that uniform heating of the deck is assured and a convenient variation of the temperature of the decks is permitted.

The oven body is of steel, heavily insulated with heat resisting material so that the outside wall temperature rises but little. The switchboard is placed on one side of the oven and has large indicating switches fully protected against dirt and damage. Separate electrical fuses are provided for each heating circuit. Electric lights are provided for the inspection of the bread. It is also furnished with a steam coil attachment for crust baking. This oven is the Edison No. 300; it has a capacity of 25 kilowatts and will hold approximately 200 pounds of bread at a time.

Second Class Stateroom

ELECTRIC GALLEY RANGES

The electric ranges in the Ritz-Carlton galley are in sections 4 feet long and each section has a top cooking surface composed of four 9 by 24-inch cast plates into which has been cast a steel encased "nichrome" heating element, so that the plate and heating unit are inseparable and practically indestructible. Each plate has an input of 4,000 watts and is controlled by a separate switch. These top plates will come rapidly to cooking temperature and can be maintained at a bright red heat. They will not warp or distort and have the decided advantage of a uniformly heated, solid top. Each section has an oven below the cooking top 18 inches high by 21½ inches wide by 28½ inches deep. This oven is well insulated to hold the heat and has two heating elements, one at the top and one at the bottom, so that the operator has complete control of the amount and direction of the heat. These ovens will easily hold 100 pounds of beef in one cut and are very well known for their excellent results in baking and roasting due to the uniformity of the heat and its control. There are six of these sections placed in two rows of three each, back to back.

ELECTRIC BROILERS

The work of broiling is provided for in a separate room where charcoal broilers are installed. As an adjunct to this service, there are two electrical broilers installed. These are of the horizontal type, having a heating area 16 inches wide by 26 inches deep, adjustable griddle and snaps to control the heating element.

MISCELLANEOUS DEVICES

There are many other smaller electrical devices installed in the serving pantries and dining room, giving the steward the equivalent advantage of what might be called "gas service" in land installations. It is impossible to get this type of service on shipboard without the use of electricity as these small devices would not be practical with coal fuel. These give the stewards ready and convenient sources of heat for heating operations between meal times and as an adjunct to the service from the galley.

Another important function is the plate warmer in the dining saloon, previously mentioned. These consist of a nicely finished serving table to conform with the dining room architecture and furnishings, having recesses in their top into which is placed a rectangular steel plate having an electrical heating element on its lower side.

OIL BURNING EQUIPMENT

The contract for the oil burning equipment for the *Leviathan* was awarded to the Peabody Engineering Corporation of New York. While not representing so large a proportion of actual material required, the vital importance of the oil burners to the success of the vessel will be recognized by all. In fact, it represents the most important single item in the entire reconditioning of the vessel.

The selection of this equipment involved the matter of ability of the burners to meet the specified requirements of the Shipping Board as to capacity and efficiency in the use of the fuel, which provided that one ton of the most viscous oil obtainable must be economically burned per hour under each boiler. Also it was necessary to consider the adaptability of the burners to the special furnaces of the German built boilers, particularly as applied to the distribution of the gases of combustion to insure economy, and to prevent local overheating and impingement of the flame on the boiler tubes and brick work.

Mr. Ernest H. Peabody, the inventor of the burner, has not only had a wide experience in burning oil fuel under many types of boilers, and under a very great variety of conditions, but is a recognized authority on marine boilers, particularly those of the watertube construction, and furthermore, he had had some special experience with a type of

S. Leviathan: (1) Bakery, (2) Ritz-Carlton Galley, Showing Electric Ranges, (3) Dough Mixing Room, (4) Detail of Electric Range, (5) First Class Galley, (6) Pastry Bakery, (7) Electric Griddle, (8) Electric Heated Serving Table.

boiler very similar to that installed on the *Leviathan*. It is interesting to note, therefore, in connection with the *Leviathan* contract, that Mr. Peabody was personally consulted in the matter of the details of installation of the furnace walls, selection of the proper refractory materials and general design of the furnaces.

The equipment consists of 230 Peabody mechanical atomizing burners and air registers, five units being installed on each of the 46 boilers. The air for combustion is delivered to the fire room by means of blowers operating under very slight pressure head. The air then passes through specially constructed air heaters arranged in the uptakes of the boilers, thus utilizing a portion of the waste heat from the gases in heating the air for combustion on its passage to the burner.

General View of One of the Boiler Rooms

After leaving the heaters the air flows through a double casing to the front and rear of the boilers, that portion which passes to the front flowing directly to the air registers, and that passing to the rear being conducted under the furnace floors through ducts, which communicate with the air box or double front on the boilers in which are located the air registers which control and deliver the air to the burners.

It will be evident, therefore, that not only is waste heat recovered from the escaping gases for combustion, but the boiler casing, including that beneath the furnace floor, is cooled by the passage of the air, and the radiation of heat into the boiler room is greatly reduced. The trials of the vessel have, in fact, demonstrated that the fire rooms of this vessel are very comfortable even under the semi-tropical weather conditions prevailing during the trial trip.

It will be noted in this connection, that this method of utilizing draft is much cooler than would be the case if the air were delivered through ducts directly to the air heaters, for the reason that all the air for combustion goes through the fire rooms and acts as a ventilating medium for the fire rooms.

Under ordinary steaming conditions the fire rooms of the

vessel will not be closed and the air pressure will be practically equivalent to that of the atmosphere. The work of drawing the air through the heaters and casings and delivering same to the air registers and thence to the burners, and also of drawing the escaping gases through the boilers into the uptakes, is therefore accomplished by the natural draft suction of the vessel's funnels, which are about 170 feet in height above the burners. Under forced conditions, the fire rooms may be closed and the air pressure raised to about one-half inch water pressure, or just about sufficient to overcome the resistance offered by the air heaters and double casings of the boiler.

The Peabody air register is well known for its simple construction, ease of regulating and controlling the air for

General View of the Engine Room

combustion and low resistance to the flow of air through same. The air control doors are arranged to form the surface of the frustum of a cone when in the closed position, and, when opened, will give the air a rotary motion as it passes to the burners. Owing to the fact that the air doors are adjacent to each other without the use of intermediate members or "door jambs," the entire surface of the cone is available for the entrance of the air, barring the very small resistance offered by the hinge bolts.

The operating gear consists of a hand wheel and lock nut communicating with a rack and pinion on the inside of the front plate of the register, which operates all doors simultaneously and holds them in a fixed position. A suitable inspection and lighting hole is provided directly above the burners, together with two additional openings which can be used for giving access for cleaning.

The burner is supported on a bracket in the center of the front plate of the register which carries a tube through which the burner is inserted when in operating condition. Quick, detachable yoke couplings serve to connect the burners to the oil delivery lines, and the yoke is so arranged that when the burner is removed, the carefully machined surface

and Suction Strainers.

Leviathan Deck Department Organization Chart

of the coupling is protected from damage. These yoke couplings are all interchangeable so that any burner can be installed in any air register at a moment's notice.

Like all mechanical burners, the atomization is accomplished by centrifugal force induced by delivering the oil tangentially to a central chamber at the tip of the burner. In the Peabody design, the tangential passages and the outlet orifice, together with the central chamber, are contained in one very carefully machined member which is easily removed and replaced when it is desired to change the size of the burner, or when it is necessary to clean out any extraneous matter which may pass the strainers and reach the burner tips.

Readers of this article will perhaps be interested to know that the "wide range" feature which is usually furnished with the mechanical burners manufactured by the Peabody Company was not supplied with the burners installed on the *Leviathan*. Thus, in the selection of the burner, the added advantage of the wide range feature played no part, and the burner and air register were approved on their merits as a "straight" mechanical burner equipment. It is believed by the manufacturers of the burner that the wide range feature could be added with little additional cost, resulting in a considerable reduction in the fire room force and added efficiency in operation.

The Largest Anchor in the World

The largest anchor in the world was recently completed at the Thurlow Works of the American Steel Foundries at Chester, Pa., for the S. S. *Leviathan*, reconditioned at the Newport News Shipbuilding and Dry Dock Company, Newport News, Va. The anchor is of cast steel, of the Dunn stockless type and weighs 33,300 pounds.

The commanding officers of the *Leviathan* and the personnel of the engine room staff are as follows:

LIST OF DECK OFFICERS

Herbert Hartley, captain.
Hubbard C. Fish, staff commander.
Kenneth B. Lowry, chief officer.
Joseph P. Linden, first officer.
Ephraim W. Higgins, second officer.
Harry Manning, second officer.
Louis M. Sanders, third officer.
John S. Bowen, third officer.
Gordon F. Danforth, third officer.
Walter E. Burns, fourth officer.
Three cadet officers.

LIST OF LICENSED ENGINEERS

Chief: Robert L. Harrison.
Staff Chiefs: John J. Fagan, Robert Douglas, William Lundy.
First Assistants: Burton L. Cartmel, Charles W. Isgar, David H. Betts.
Second Assistants: E. L. Dawson, M. P. Iverson, Marshall Cowell.
Senior Thirds (18): E. J. Deeds, E. J. Landers, James Senlle, George L. Clow, G. H. Begley, G. C. Merry, L. L. Sztakowski, A. R. Brebner, W. M. O'Connor, A. H. Claudius, M. T. Minnihan, W. J. Brookie, A. Schlexer, F. H. Kipper, Thomas Webster, A. M. Davis, H. J. Williamson, C. Hunt.
Junior Thirds (16): J. W. Thomas, W. R. Fernald, W. J. Smith, E. L. Powell, J. F. Halle, C. C. Clark, W. G. Hawkins, C. H. S. Hallett, F. B. Mulroy, J. T. Olson, J. A. Smith, W. B. Schaum, J. E. Bacorn, J. A. Hanna, F. J. Sholl, H. G. Thompson.
Hydraulic Engineers: W. E. Wallace, D. Coogan, T. H. Bowker.
Deck Engineers: J. L. Moore, E. L. Moritz, F. Lewis.
Fourth Assistant Engineers: E. F. Sawyer, E. J. Thawley, G. C. Tucker.
Refrigerating Engineers: G. W. Bailes, Thomas Egan, H. Franklin.
Electricians: R. J. Cross, J. R. Dale, A. F. Neely.
Assistant Electricians: E. H. Quos, T. E. Brown, A. J. Cann, W. F. James, J. C. Howard, T. Anderson, J. J. Elan, C. G. Snowden, H. R. Macy.
Sanitary Engineers: A. G. McCarthy, James Sheridan, A. W. Thomas, J. H. Garriss, J. E. Johnson, J. J. Maynard.
Boiler Makers: S. Crawford, J. Boyle.

MOTORSHIP LAUNCHED AT BRISTOL.—Messrs. Chas. Hill and Sons, Albion Dockyard, have just launched the third of the ocean-going motor vessels that have been built in Bristol. The other two were the British India Steam Navigation Company's passenger and cargo ships *Dumra* and *Dwarka*. The new vessel, the *Margretian*, is the largest of the three and is only 15 feet shorter than the largest vessel ever launched in Bristol. Her dimensions are: Length, 310 feet; breadth, 43 feet 6 inches; depth, 26 feet. She will be fitted with two internal combustion engines and twin screws. Her gross tonnage is about 2,800. The vessel has been built to the order of Messrs. Owen and Watkins Williams & Company, Cardiff, proprietors of the Golden Cross Line, having a regular service between Bristol and the Mediterranean in the general cargo and fruit trade.

Marine Standards Committee Ready for Action

Constitution and Rules of Organization Adopted—Method of Developing Standards Outlined — Members of Technical Committees Appointed

THE constitution and rules of organization and procedure under which simplification and standardization in the shipping industry will be carried out have been completed. At a recent meeting in New York of the executive board of the American Marine Standards Committee, every provision was made for carrying out in detail the important work in all branches of the field. Great credit is due Secretary Hoover, of the Department of Commerce, for starting and sponsoring this movement in every industry in his campaign on the "Avoidance of Waste." Many branches of the

has been developed as far as the tentative stage by a subject committee, it then goes to the technical committee under which it is working, and, if passed by that body, it will then be forwarded to the secretary. The secretary will then promptly submit an outline of the standard to all concerns interested and invite their comments. The proposed standards, together with such comments as come in in a reasonable time, will be submitted by the secretary to the executive board. The board may order future study and send it back to its technical committee with comments or it may do one of three things, namely:

1. The board may, by a favorable majority vote of all its members, approve it as *Suggested American Marine Practice*, or
2. It may, by a favorable two-thirds vote of all its members, approve it as a *Tentative American Marine Standard*, or
3. It may, by a favorable three-fourths vote of all its members approve it as an *American Marine Standard*.

The votes of the executive board upon any proposed standard will be obtained by ballot.

To the Shipbuilders, Manufacturers of Appliances and Supplies for Marine Use and the Ship Operators of the United States

June 13, 1923.

Gentlemen:

The American Marine Standards Committee, created by the shipbuilders and manufacturers of appliances and supplies for marine use for the purpose of erecting standards and securing simplifications in many elements of ship construction, etc., promises to be of very great importance to the industry.

The Department of Commerce has placed at the disposal of the Committee the services of its Division of Simplified Practice and the Departmental laboratories for the development of such standards and simplifications as the Committee may think wise to recommend to the industry.

The results obtained in other industries by movements of this character originating from the industries themselves have been of the most important character and all contribute to overcome the natural handicaps in which we are placed in international competition.

I am glad that the Department should be able to co-operate with the industry in this movement and I believe the support of the Committee by the industry itself will bring important results to the manufacturers and shipowners.

Yours faithfully,

(Signed) HERBERT HOOVER.

manufacturing industry have started this work and it is particularly gratifying that shipping, in which maximum efficiency is an absolute necessity, has succeeded, largely through the efforts of Colonel E. A. Simmons, president of the American Marine Association, in enlisting the services and cooperation of our most prominent naval architects, marine engineers and ship operators.

Without the cooperation of the best men in the field, the movement would have no chance of success. This was fully realized and great care was taken in preparing the constitution and rules to prevent the possibility of any standard being adopted that had not received the most careful and authoritative consideration.

HOW STANDARDS WILL BE DEVELOPED

In order to do this, the executive board has divided the work among five technical committees which in turn will appoint subject committees for specific items. When a standard

REQUIREMENTS FOR MEMBERSHIP

Having shown how standards will be developed, it is appropriate to explain how individuals, companies, societies, government departments, and all either directly or indirectly concerned, can secure membership and take part in the work of the organization. The mass membership is composed of individuals, partnerships, corporations, societies, Government departments, public bodies, etc.

It will be noted that the mass membership is divided into two divisions, those who contribute funds or direct service and those who only cooperate in technical work. From these two classes of member bodies there is drawn the representative membership from and by which the members of the executive board will be taken and elected.

THE EXECUTIVE BOARD

The present executive board, every member of which is widely known, is constituted as follows:

Colonel E. A. Simmons, president, American Marine Association, 30 Church Street, New York City, representing the American Marine Association, chairman; Captain R. D. Gatewood, U. S. N., manager, Department of Maintenance and Repair, United States Shipping Board Emergency Fleet Corporation, 45 Broadway, New York City, representing the U. S. Shipping Board, vice-chairman; Charles F. Bailey, engineering director, Newport News Shipbuilding & Dry Dock Company, Newport News, Va., representing shipbuilders for engineering details; Hugo P. Frear, naval architect, Bethlehem Shipbuilding Corporation, Limited, Bethlehem, Pa., representing shipbuilders for hulls and fittings, also the Atlantic Coast shipbuilders' Association; E. H. Rigg, naval architect, New York Shipbuilding Corporation, Camden, N. J., representing the Society of Naval Architects and Marine Engineers; William Francis Gibbs, president, Gibbs Brothers, Incorporated, 1 Broadway, New York City, representing the American Steamship Owners' Association; Captain C. A. McAllister, vice-president, American Bureau of Shipping, 50 Broad street, New York City, representing the American Bureau of Shipping; Captain John F. Milliken, secretary and treasurer, Neptune Association, 21 Pearl Street, New York City, representing masters, mates and labor organizations; Rear Admiral J. D. Beuret, U. S. N., chief of Bureau of Construction and Repair, Navy Department, Washington, D. C., representing the Bureau of Construction and Repair, Navy Department (alternate member, Rear Admiral Robert Stocker (C. C.), U. S. N., Bureau of Construction and Repair, Navy Department, Washington, D. C.); Admiral J. K. Robison, U. S. N., chief of the Bureau of Engineering, Navy Department, Washington, D. C., representing the Bureau of Engineering, Navy Department (alternate member, Captain J. T. Tompkins, U. S. N., Bureau of Engineering, Navy Department, Washington, D. C.); Brigadier General H. Taylor, U. S. A., Corps of Engineers, United States Army, War Department, Washington, D. C., repre-

sending the Corps of Engineers, U. S. A.; General George Uhler, supervising inspector general, United States Steamboat Inspection Service, United States Department of Commerce, Commerce Building, Washington, D. C., representing the U. S. Steamboat Inspection Service; John W. Gray, assistant to general manager, Newport News Shipbuilding & Dry Dock Company, Room 410, Harrison Building, Philadelphia, Pa., representing the American Society of Mechanical Engineers (alternate member, H. H. Brown, managing editor, MARINE ENGINEERING AND SHIPPING AGE, 30 Church street, New York City).

The Technical Committees that have been appointed to supervise simplification and standardization are as follows:

COMMITTEE ON HULL DETAILS

W. A. Dobson, naval architect, William Cramp & Sons' Ship and Engine Building Company, Philadelphia, Pa., chairman; E. L. Stewart, naval architect, Standard Oil Company of New Jersey, 26 Broadway, New York City; W. R. Bean, assistant naval architect, New York Shipbuilding Corporation, Camden, N. J.; A. B. Brown, naval architect, Sparrows Point Plant, Bethlehem Shipbuilding Corporation, Sparrows Point, Md.; J. W. Hudson, naval architect, Sun Shipbuilding Company, Chester, Pa.; H. F. Norton, naval architect, Newport News Shipbuilding & Dry Dock Company, Newport News, Va.; Axel Rossell, chief constructor, Gibbs Brothers, Incorporated, 1 Broadway, New York City; Commander H. S. Howard (C. C.), U. S. N., in charge of new design, Bureau of Construction and Repair, United States Navy Department, Washington, D. C.; Horace H. Thayer, consulting naval architect, 119 South 4th street, Philadelphia, Pa.; Hugo P. Frear, naval architect, Bethlehem Shipbuilding Corporation, Limited, Bethlehem, Pa.

COMMITTEE ON ENGINEERING DETAILS

A. A. Howitz, chief engineer, Sun Shipbuilding Company, Chester, Pa., chairman; Charles P. Wetherbee, vice-president, Bath Iron Works, Limited, Bath, Me.; M. L. Katzenstein, manager, Marine Department, Worthington Pump & Machinery Corporation, 115 Broadway, New York City; W. W. Smith, chief engineer, Federal Shipbuilding Company, Kearny, N. J.; J. B. Crew, chief engineer, New York Shipbuilding Corporation, Camden, N. J.; R. Warriner, chief engineer, Bethlehem Shipbuilding Corporation, Ltd., Quincy, Mass.; James S. Milne, chief engineer, Todd Shipyards Corporation, 25 Broadway, New York City; John F. Metten, chief engineer, William Cramp & Sons' Ship & Engine Building Company, Philadelphia, Pa.; Commander S. M. Robinson, U. S. N., head of design division, Bureau of Engineering, U. S. Navy Department, Washington, D. C.; Charles F. Bailey, engineering director, Newport News Shipbuilding & Dry Dock Company, Newport News, Va.; A. E. Ballin, president, McIntosh & Seymour Corporation, Auburn, N. Y.; A. B. Homer, marine engineer, Bethlehem Shipbuilding Corporation, Ltd., Bethlehem, Pa.

COMMITTEE FOR SHIP OPERATION, DETAILS AND SUPPLIES

A. S. Hebble, superintending engineer, Southern Pacific Lines, Pier 49, North River, New York City, chairman; R. F. Hand, assistant manager, marine department, Standard Oil Company of New Jersey, 26 Broadway, New York City; Walter L. Green, Jr., superintending engineer, Luckenbach Steamship Company, 44 Whitehall street, New York City; H. M. Wesson, superintending engineer, United American Lines, Inc., 39 Broadway, New York City; W. B. Ferguson, superintendent of construction, Newport News Shipbuilding & Dry Dock Company, Newport News, Va.; N. J. Pluymert, marine superintendent, Standard Transport Company, 26 Broadway, New York City; P. H. Harwood, marine manager, Pan American Petroleum & Transportation Company, 120 Broadway, New York City; George B. Drake, manager, marine department, Texas Company, 17 Battery Place, New York City; Captain Henry M. Seely, supervising inspector, second district, U. S. Steamboat Inspection Service, Custom House, New York City; John W. Gray, assistant to general manager, Newport News Shipbuilding & Dry Dock Company, Room 410, Harrison Building, Philadelphia, Pa.; H. C. Higgins, district agent, division of operations, U. S. Shipping Board Emergency Fleet Corporation, Philadelphia, Pa.; Captain H. L. Wyman, U. S. N., assistant to chief of Bureau of Engineering, Navy Department, Washington, D. C.; L. B. Shuman, principal assistant engineer, U. S. District Engineer's Office, Witherspoon Building, 1321 Walnut street, Philadelphia, Pa.

Two other committees are yet to be appointed; namely, the committee on port facilities and that on manufacture and construction.

The secretary of the organization is Mr. A. V. Bouillon, Division of Simplified Practice, Department of Commerce, Washington, D. C.

A special committee was appointed at the recent meeting of the board with power to designate specific subjects to be taken up by the technical and their subject committees.

Leviathan on Trial Trip Breaks World Records

(Continued from page 393)

before, during and after the reconditioning were shown and addresses were made by Mr. Lasker, Mr. Gibbs, Mr. Ferguson and by Edward Price Bell on behalf of the newspaper correspondents. In these addresses it was shown that the work of reconditioning, including the trial trip, has been done within the appropriation of \$8,200,000 made on estimates of two years ago, that the contracts were performed without extras and that the trial trip, which had been criticised in some quarters, had been made within the estimated cost of \$120,000. Mr. Lasker stated that the Newport News Shipbuilding and Dry Dock Company had suffered a loss of \$1,200,000 in its part of the contract, which amounted to \$6,100,000, partly because while the bids were made during a time of unemployment, the work was completed in a time when there was a great demand for labor. He expressed great appreciation of the character of the work done and the degree of cooperation shown by the Newport News company and said that to reproduce the vessel in its present condition would cost \$25,000,000.

TRIAL TRIP NECESSARY

Mr. Ferguson also expressed appreciation of the attitude shown by Mr. Lasker and the Shipping Board in backing up the recommendations of the experts without the interference that sometimes characterizes Government work.

As demonstrating the necessity for a trial trip, which had been denied by some critics of the board on the ground that it was only a junket, it was shown that before all the detailed functions pertaining to the operation and service of the vessel could be expected to be performed with the smoothness desired of the greatest ship in the world time would be required to give the men an opportunity to work together and develop a thorough team work; also that the ship had not been run under full power before because its bottom had not been cleaned for 3½ years and that during the slow speed trip from Newport News to the drydock at Boston a cracked propeller hub had been discovered which would have resulted in excessive strain in the shafting and might have caused considerable damage if an attempt had then been made at high speed. There is also a large number of underwater valves which had to be overhauled in drydock. Mr. Ferguson said it was highly complimentary to his company to suggest that the ship did not need a trial but that for the Government to accept it without one would hardly have indicated prudence and that his company could not afford to conduct the trial itself because it was impossible to fully insure so large a ship.

Mr. Lasker said that although it had been almost kept a secret even from him, the attaining of the world speed record was one of the objects Mr. Gibbs had had before him all the time and Mr. Lasker and Mr. Ferguson both emphasized the need for an American merchant marine and the impetus that would be given toward it by the successful completion of the new *Leviathan*.

Mr. Lasker also said that while he did not believe in Government operation and while he had had "fifty years of hell in two winters" as a Government official, apparently the President and the Shipping Board now have no alternative to direct Government operation of the Shipping Board fleet and that if we cannot have a merchant marine in any other way he is willing to have it under conditions which he does not like.

Tests of the machinery and equipment were conducted by a trial board consisting of Captain R. D. Gatewood, chairman, Harry Brown, J. F. Metten, A. S. Hebble, J. E. Bailey, Captain W. E. Griffith, Captain C. A. McAllister and C. A. Greaser, secretary. All trial data in connection with the main machinery and engine room auxiliaries, including auxiliary lighting equipment, were obtained for the agent under the direction of Henry C. E. Meyer, chief engineer. All other trial data, including all hull engineering, passenger equipment, galley and pantries, etc., were obtained under the direction of Axel Rossell, chief constructor, and G. A. Anthony, assistant chief constructor.

TESTS

Among the tests made in addition to the obtaining of engine room trial data were:

500 kilowatt geared turbo generator was tested for one hour carrying full service load, exhausting against back pressure, exhaust being used in feed heaters or bled to main low pressure turbines as required in service. Other machines were operated in parallel electrically, exhausting to common auxiliary exhaust.

Lifeboat tests.

Test of hydraulically operated watertight doors controlled from bridge.

Test of Rich fire detecting and extinguishing system covering the cargo holds, fore and aft. Smoke was produced first in the forward hold, later in the after hold. The detection cabinet determined the location of the smoke and steam was turned on momentarily to see that it is in operating condition.

Test of new 2 kilowatt vacuum tube radio telephone.

Test of whistles, siren and engine order telegraphs.

Test of steering telegraph and anchor telegraph.

Test of deep sea sounding machine.

Test of new Sperry 450,000,000 beam candlepower searchlight.

Test of emergency lighting (storage batteries).

Test of the various ventilation systems, 257 in number, operated at full power.

Test of new 6 kilowatt vacuum tube radio telegraph.

Test of pneumatic draft gages.

Test of manually operated stand-by engine.

Hour test of electrically operated fog bell.

Test of Kent clear view screens.

Test of aero automatic fire alarm from different circuits throughout the vessel.

Test of manual fire alarm system from different boxes throughout the ship.

Test of salt and fresh water sanitary system.

Gyro compass test including change of master compasses and transfer of repeaters.

Test of annunciator system and loud speaking telephones.

Test of 2 kilowatt radio spark set.

Test and inspection of all culinary apparatus.

Test of submarine signal apparatus.

Test and inspection of elevators and dumbwaiters.

The congressional guests joined in the general enthusiasm over the success of the run and in the praise of the Shipping Board official that had brought it about. Among those who gave expressions of this character to the newspaper men for transmission to their papers by radio were Senator Fletcher of Florida, Senator-elect Edwards of New Jersey, Senator Oddie of Nevada, Representative Madden of Illinois, chairman of the House Appropriations Committee; Representatives Gallivan of Massachusetts, McFadden of Pennsylvania, Bloom of New York, Burton of Ohio and Britten of Illinois. Representative Madden also referred to the guests on the "junker" as "the best behaved and most circumspect crowd I have ever seen" and said he had been convinced of the necessity for a trial trip.

NEW RADIO RECORD

New records were also established during the trial trip for the volume of traffic handled by the radio telegraph system. David Sarnoff, vice-president, and G. H. Porter, general superintendent of the Radio Corporation of America, gave their personal supervision to the handling of the large volume of messages handled, which, largely because of the great amount of newspaper copy sent, was estimated at 15,000 words a day. Mr. Sarnoff said that there were more messages sent and received daily on the ship than are handled every 24 hours between the United States and any European country.

PURSE FOR ENGINE MEN

At an evening entertainment on June 24 the guests on board contributed a fund of \$5,932 to be distributed under the direction of Mr. Lasker among the officers and crew of the engine room.

Farmers-Manufacturers Conference at Cincinnati Pledges Support for Merchant Marine Campaign

THE Middle West Farmers-Manufacturers Conference held at Cincinnati, Ohio, on June 28 and 29 has developed the fact that all classes of our people believe at America should have its own merchant marine. There is, however, a difference of opinion as to how this great object can be accomplished but there can be no doubt that the best way to iron out these differences is to get the representatives of commercial, farming and manufacturing organizations together around one table.

Among the speakers who addressed the conference from the standpoint of the shipping industry were E. C. Plummer of the Shipping Board, Winthrop L. Marvin of the American Steamship Owners' Association, N. O. Pedrick of the United States Ship Operators' Association and Frank J. Shipman of the American Marine Association. Mr. Shipman invited the conference to attend the American Marine Congress to be held next November in New York and this invitation upon the motion of Matthew Hale was accepted.

The principal speeches by representatives of the Middle West were made by Senator Pomerene and O. E. Bradfute, president of the American Farm Bureau Federation.

Senator Pomerene said, "Let the chambers of commerce, manufacturers' and farmers' associations study this problem and pass resolutions and then tell their congressmen what

they want and it will come to pass. We must never again be in the position that we were when the Great War broke out."

Mr. Bradfute said that it was only recently that the farmers had been invited to sit at the council table in maritime matters. He believed that the farmers would support the merchant marine and declared that there were no class of men more loyal to American institutions. He pointed out that the membership of the organization he represented was composed of over one million farms and that they had a system of obtaining, in a very short time, the consensus of opinion of their membership on any subject through the questionnaire system.

RESOLUTIONS ADOPTED BY MIDDLEWEST FARMERS-MANUFACTURERS CONFERENCE

It is hereby declared to be the purpose of the Middle West Farmers-Manufacturers Conference to develop the foreign trade of the Middle West, through education, conferences and the co-ordination and co-relation of the various agencies, such as manufacturers' associations, farmers' organizations and chambers of commerce now studying the subject through their several traffic committees, which studies are necessarily either local or related to a single industry, to the end that the Middle West may participate in the foreign trade of the nation to the fullest extent and upon equality of opportunity so far as that is possible.

Our distance from the sea being approximately a thousand miles greater on the average than any nation with which we compete,

and our own seaboard markets nearer to foreign markets in point of freight costs than much of our own territory, transportation becomes a major purpose of this conference.

The development of seaways that will move the sea base inland, or inland waterways that will furnish routes of low resistance costs to the sea base, are of especial concern to this conference.

We stand unreservedly for an American merchant marine, without subsidy, as an indispensable link in our delivery system. And in the place of subsidy we submit the following as offering a probable solution of the problem and recommend its most careful consideration:

1. A system of preferential customs duties on goods carried in American ships.
2. A system of preferential rail rates for goods and passengers carried in American ships.
3. A system of preferential tonnage dues for American ships.
4. Allowing our railroads to apply export rates on materials used in the construction of American ships and on supplies used therein.
5. Laws compelling American officials traveling at Government expense to use American ships.
6. Laws providing that a certain percentage of our immigrants be carried on American ships.
7. Such other preferences for American ships as may result in benefit to the American shipper and may secure closer cooperation between the American shipper and the American merchant marine.

Our ocean transportation should be thoroughly co-ordinated with our inland transportation system, through the establishment of through joint rail and ocean freight and passenger rates from the Middle West to foreign markets. In this way only can the shipper in the interior know the actual cost of his goods delivered in those markets.

Our shippers of the interior should be allowed to file their export declarations at the custom houses of the cities where shipments originate.

We emphatically urge the Shipping Board to postpone any radical change of policy until Congress convenes and until the people of the country have an opportunity to express their views regarding additional merchant marine legislation. And we urge the Shipping Board in the meantime to work out some plan of operation through private steamship companies, fair to the Government, shippers and to the companies, which will enable those companies to buy the ships as soon as shipping conditions permit and as soon as additional legislation is secured.

We further recommend the following resolutions:

BE IT RESOLVED, that, we favor an equalization of export rail rates to all ports from the Middle West, and of import rail rates from all ports to the Middle West, to secure additional outlets to the sea and to make all of our seaports available to the Middle West on equal terms.

BE IT FURTHER RESOLVED, that, we favor the establishment of lower ocean rates to and from South Atlantic and Gulf ports where distance favors those ports, as long as lower ocean rates from or to North Atlantic ports are in effect where distance favors North Atlantic ports.

BE IT RESOLVED, that we are opposed to a monopoly in shipping, whether it be an American monopoly or a foreign monopoly, and we quote with approval the anti-monopoly clause of the Administration's recent Shipping Bill:

"It is hereby declared to be the policy of Congress to discourage monopoly in the American merchant marine, and, in pursuance of this policy, the Shipping Board is directed, in the development of its sales and its assignment policy, to continue as far as possible and practicable, subject to the provisions of this section, all existing steamship routes and regular services, and to endeavor in every way to bring about the permanent establishment of such routes and services, and their retention, as far as possible, in the hands of persons having the support, financial and otherwise, of the domestic communities primarily interested in such routes and services."

BE IT FURTHER RESOLVED, that we are opposed to any curtailment of the existing trade routes as a thing calculated to restrict our outlets; to congest our traffic in a few ports and upon a few railroads leading to those favored ports; and to increase car shortage, and;

BE IT FURTHER RESOLVED, that, in our judgment the time has not arrived when the capital of the small American investor can be profitably or safely invested in American flag ships, and, therefore, we believe that the forced sale of American flag ships at this time will have the effect of gradually driving this vast tonnage of shipping into the hands of selfish monopolies which will use the tonnage with an eye single to profits and without thought of the development of American agriculture, manufacturing and commerce, and;

BE IT FURTHER RESOLVED, that, we urge the President and the Shipping Board to do everything to encourage the retention and

the ultimate purchase of the new trade routes by "persons having the support, financial and otherwise, of the domestic communities primarily interested in such routes and services"; thus carrying out the spirit and the letter of the Merchant Marine Act of 1920 which very definitely contemplates the ultimate purchase of the new trade routes by independent local companies and not by shipping monopolies controlled by and interested primarily in other ports.

Shipping Board Prepares for Government Operation

THE United States Shipping Board, having failed to receive satisfactory bids for any considerable number of its ships, has begun the preparation of plans for direct government operation of its fleet. At a meeting held on June 4 the board adopted a resolution appointing a committee consisting of the chairman, the vice-chairman and Commissioner Thompson to prepare a plan to be submitted to the board "with a view to the formation of such companies or organizations, to be owned and controlled by the Shipping Board, as it may ascertain to be necessary for the purpose of operating sufficient vessels to fully cover world trade routes under the American flag consonant with the greatest possible economy and efficiency in direct government operation."

Chairman Lasker, who retired on June 19, will be succeeded on the committee by the new chairman, Edward Farley. During the period of the study and until the plan evolved has been adopted by the board, operations will proceed through managing agents as at present. It is the hope of the board, however, that the new plan will soon be fully operative, as in principle many of the details have already been developed.

Commissioner Lissner reported to the board the results of the negotiations had in New York by the committee representing the board in connection with bids for routes now operated by the government and said that but three or four promising bids remained. The board instructed the committee, together with the chairman, to continue the negotiation, so that when the new plan is determined upon the board will know just which of its lines, if any, are to pass into private hands.

The bids which have been considered by the committee included one from Norton, Lilly and Company, for certain vessels operating from New York to the east coast of South America; the Argo line for two ships between New York and the United Kingdom and the Pacific coast; the Orient, the Columbia Pacific for twenty ships from the Pacific coast to the Orient; Mayor Rolph of San Francisco and associates for ships between San Francisco and Australia; the Robt. Dollar interests for ten passenger vessels between the Pacific coast and the Far East; the Pacific Mail for five ships operated out of San Francisco, and W. R. Grace and Company for two ships to the west coast of South America.

RETIRING CHAIRMAN OF SHIPPING BOARD REVIEWS HIS ADMINISTRATION AND MAKES RECOMMENDATIONS

In a letter to President Harding, announcing his retirement as chairman of the United States Shipping Board, Albert D. Lasker has given a report on the accomplishments of the board during the two years of his chairmanship. Among the achievements Mr. Lasker mentions are the settlement at 12 cents on the dollar of claims aggregating \$20,000,000; the bringing of the Emergency Fleet Corporation out of chaos into an economic, efficient and distinct entity; the reduction of its deficiency from \$16,000,000 a month to \$4,000,000 a month; the development of commerce through the operation of American ships and the disposal of surplus real estate and materials. At the end of the current fiscal year the Shipping Board would have on deposit in the

Treasury, Mr. Lasker stated, \$125,000,000, as against a total cash reserve of \$4,000,000 it had when Mr. Lasker took office. After reviewing the administrative work accomplished, Mr. Lasker made recommendations concerning the proposed government operation of America's merchant marine in the event the negotiations for the sale of the fleet to private American individuals are not successful.

Mr. Lasker said that since the failure of the subsidy bill and as it appeared that most of the bids for the government fleet would be inadequate, the only apparent alternative is to "go the full length of direct government operation," but always with a view to ultimate sale to private owners. In the event of failure to sell the ships on an adequate basis, therefore, he recommended the creation by the Emergency Fleet Corporation of 12 to 18 subsidiary corporations to operate the existing freight lines, with about 250 ships; the use of approximately 200 remaining ships as a reserve, some of them to be equipped with Diesel engines and allotted to the operating companies; the sale of the other ships at the best prices obtainable and the scrapping of those for which the board is unable to find a purchaser at home or abroad.

Hudson River Day Line Steamer *De Witt Clinton* Converted to Oil Burner

BEFORE entering her regular service this summer the Hudson River Day Line steamer *DeWitt Clinton* was converted from a coal to an oil burner. The vessel is a twin screw steel steamer of 3,539 gross tons, propelled by two four-cylinder triple expansion engines, each developing 2,243 indicated horsepower, supplied with steam

Oil Burning Equipment on One of the Boilers. At Right (from Left to Right) Are Chief Engineer R. G. Siter and Second Assistant Engineer Robert Tell

185 pounds per square inch by six 2-furnace Scotch boilers, working under Howden's heated forced draft and having a total heating surface of 12,417.6 square feet. Peabody oil burning equipment of the most improved type was installed in the engine room staff of the steamer, the tanks for carrying the oil fuel being installed by W. & A. Fletcher Company. The oil burning equipment, supplied by the Peabody Engineering Corporation, New York, comprises, in addition to the Peabody-Fisher wide range burners and their necessary piping, two Dean horizontal duplex oil pumps, 6 inches by 6 inches by 6 inches, two Griscom-Russell straight tube five-gallon oil heaters (either set being of sufficient size to handle entire load) and a 3-inch suction and a 2-inch discharge line both of the duplex type.

The special feature of this installation is that it maintains the good points of the Howden heated forced draft system while it avoids the objectional feature of using, when

Duplicate Sets of Oil Pumps Are Installed

burning oil, the cast iron fronts designed for coal burning, in which the air is unevenly distributed. In this case the Howden coal fronts were removed and the latest type Peabody double ported registers were fitted, with an outer casing connecting directly with the hot air ducts leading from the Howden heaters, thus using the desirable features of the Howden system, while avoiding the undesirable points.

This arrangement gives a double control of the air to the burners, which can be very accurately adjusted. As the Peabody-Fisher wide range burners, fitted with their central control valve, were installed in this case, the engineer has absolutely under his control the handling of both air and oil so as to give the best results in regard to the amount of oil

General View of After Boiler Room

consumed and the power developed. This was well demonstrated on the recent trial trip of the vessel, when the ship was brought from full speed ahead to a stop and the steam pressure was maintained without blowing steam, changing tips or putting out fires, no smoke showing during the change. This arrangement also gives ready means of running the vessel under natural draft, when it is not desired to operate the blower fan.

This installation was laid out by Mr. E. B. Sadtler, of the Peabody Engineering Corporation, and carried out by Chief Engineer Russell G. Siter, of the *S. S. DeWitt Clinton*, and his able assistant, Mr. Robert Tell.

America Will Fight for Place on the High Seas

Nothing Will Be Overlooked in Training Our Merchant Marine to Meet Aggressive Foreign Competition on an Even Footing

By "Old Scotch"

WE are passing through a momentous period for the future of Mr. American Merchant Marine. The industry is somewhat "groggy" from what looked to be a knockout blow, when Congress failed to do anything constructive for our champion, and left us groping around in a dazed condition to get up steam and energy enough to make a further attack on our old opponent, Mr. Aggressive Foreign Shipping. We are gradually wiping the blood out of our eyes, getting back our breath, and sparring around the ring for another opening.

Things look rather squally at the present writing and unfriendly "bookmakers" (editors of foreign shipping papers) are offering odds against our ultimate success in this prize ring of shipping on the seas. Our Uncle Samuel, while unwilling apparently to give us any life-inspiring oxygen treatment, is delivering to us the ultimatum that, if we do not resume the battle on our own strength alone, he will step in the ring himself for a round or two, and show us how to battle.

GOVERNMENT OWNERSHIP NOT THE FINAL ANSWER

Of course, Uncle Sam has a couple of brass knuckles on his fists, in the shape of a strong Treasury behind him, but such, while it lasts, is not teaching us the game of fighting. Besides that, the spectators who put up the coin for Uncle to battle with are a fickle bunch, like all other gatherings at sporting events, and at a critical time are liable to yell "Take him out," if he wabbles a bit in the encounter.

Naturally, rather than to see the fight called off entirely, we are willing to see Uncle do the fighting himself, at least until our breath is fully recovered, and we can take off a little more of the extra weight we have been carrying, and be able to get back in the ring ourselves for another try for the championship. As the gate receipts for events of this kind are very lean just at present, we had better bestir ourselves to getting in better condition, while Uncle keeps our opponents busy with his brass knuckles.

AMERICAN SHIPPING MEN WILL "CARRY ON"

No, we are not discouraged, and we haven't lost sight of the prize for which we are battling. This extra weight we are carrying can and will be worked off before we again tackle our enemies. When Uncle lets us take our place in the ring again, we would like a few cheers from the ring-side, as nothing helps so much in a fight of this kind as to know that your own gang is with you.

Our seconds and trainers have outlined very good methods of training to reduce our surplus weight, and to harden up our muscles. The training process prescribed is now going merrily along on all sides. Already plans are in process for unloading the greatest part of our excess weight, in the shape of the great fleet of idle ships that stand as a menace to the real competition we are about to enter. Uncle has charge of this part of our weight reduction, and, if rumors be true, a very considerable portion of the laid up fleet is to be "scrapped" or "canned" whichever way may seem best to accomplish the ultimate purpose.

PART OF IDLE FLEET TO BE CONVERTED TO MOTORSHIPS

Such of the fleet which represent good fighting muscles are to be retained and put on the firing line, backed for the time being by Uncle. Others whose muscles are somewhat flabby, due to bad digestive apparatus in the shape

of inefficient machinery, will have this defect remedied by the installation of Diesel engines, which will make of the real hardened muscular constituents of the fighting body of our merchant marine.

FUEL ECONOMY IMPROVING

The overweight of inefficiency in operation in existing ships now being used on the firing line is being reduced on all sides. The Shipping Board's fuel economy efforts are getting more and more in evidence: The training of men in the proper and efficient use of fuel oil is showing better results all along the line, as the number of graduates of the League Island School are being distributed throughout the merchant marine. These graduates not only show better results, as the direct effect of their intensive training, on the ships which they operate, but they are rapidly disseminating the knowledge which they have received to others with whom they are associated who have not received the benefits of the special training. This whole effort will harden up a most important muscle in our fighting body on the competitive seas.

COST OF REPAIRS BEING REDUCED

The cost of repairs has heretofore been a decidedly flabby muscle and a cause of much "overweight" in our fighting abilities. Very cheerful results are now being obtained from the increased skill and fighting spirit of the men who handle this particular branch of the training activities in hand. Fighting spirit appeals to the average American, and this being inculcated in our sea-going scrappers to a splendid degree, as each engineer has it impressed upon him that he must do his individual part in reducing repair costs, if our fighting merchant marine is to have a chance in the great international prize fight on the sea.

Inventors are rushing to the aid of our fighter, in the shape of improving the muscles in use by bringing out new ideas, for economizing in fuel consumption. Feed water heaters, superheaters, evaporators and economizers are receiving the most intensive study from the men who know most about these essentials to the economical use of fuel and the reduction of repair costs.

In training a fighter of the type we want our merchant marine to be, it is not always best to take too much consideration of the first cost of essentials of this kind, as it results we are after. High cost apparatus which greatly reduces the daily cost of operation is oftentimes a very cheap investment to make. In training a human fighter for a contest involving tremendous stakes, as modern fistic encounters do, just note how little heed is paid to the first cost of such essentials as the best quality of food or training apparatus to put the scrapper in shape for the great event. Results alone count when you are out to accomplish a definite object, whether in fistic encounters or in its parallel contest for a right to conduct a good part of our own commerce on the seas.

As this is to be a "gruelling" contest, as sport writers usually say, the preparation of our champion must be thorough and begin with the elementary essentials.

MARINE STANDARDS COMMITTEE TO ELIMINATE WASTE

The American Marine Standards Committee suggested by Uncle, through his Department of Commerce, is now launched and ready to begin its part of the training process.

The general idea that this movement was to be conducted by our Uncle as one of his contributions to the preparation of our fighter is entirely erroneous. Uncle's function in this matter is merely to wave the fan and encourage the fighter between rounds. Its sole purpose is to eliminate waste at the training table. Representatives of all the branches that are constructing our fighting merchant marine are to get together and by mutual conferences prepare standards for all details, which lend themselves to standardization, and in this way to reduce some of the "overweight" entering into the shipping body.

This training phase is also to extend to the handling of the fighter after he goes into the ring. All waste motions must be eliminated in looking after our sea pugilist between rounds, which corresponds to the times when the ships are in port. These periods must be given the best and most efficient attention, so the A.M.S.C., through that branch of its activities, has enlisted some of the best talent in the country to cut out waste and standardize our activities while the ships are in port. If they are handled properly and expeditiously, they will be freshened up for the real fighting in each succeeding round.

EXPERIENCED COUNSELLORS AT HAND

At all ringsides it is usual to have experienced men, who themselves have long engaged in fistic encounters, to counsel and advise the active participant in the fray at hand. In

our sea-fighting contest we must have such counsellors to aid us, drawn from the ranks of the experienced in the fighting game. We do not have such a large number from which to choose, but, such as we have developed in the small fights we have been through will make up for quality in what they lack in numbers.

When we are all set for the fray, as we must be at no distant date, if Uncle succeeds in holding off our opponents while he is temporarily occupying the ring, our champion will go in for the fight of his lifetime. The fight is already being widely advertised. The battling ground is chosen, the seconds and trainers are working hard to get their men in shape. The stakes are enormous, and are measured in millions of dollars. The world at large will furnish the spectators, and the American contingent at the ringside will have to be well organized to cheer on their champion, as each one present is vitally interested in the results. International rules will govern the contest, and there must be no foul blows resorted to by either contestant.

Secure your tickets early for the world's greatest contest between Mr. American Merchant Marine, the young champion of the Western Hemisphere, and Mr. Aggressive Foreign Shipping, the victor in many hard-fought contests heretofore.

Will young fighting blood bow to this hardened old fighter of the seas? Is the question to be answered.

We'll say NO.

An Analysis of Claims of the Electric Drive Over the Geared Drive

By J. C. Shaw*

VARIOUS articles and papers have been published and read, from time to time, in the technical press and before the different societies advocating the steam-electric drive for marine propulsion. These have been conspicuous for the scarcity of any real figures to substantiate the claims for the superiority of this drive, the data being mostly theoretical, and based on assumptions generally better known to the authors.

An excellent example of one of these articles is that which appeared in the May issue of MARINE ENGINEERING AND SHIPPING AGE by Messrs. Watson and Thomas, of the General Electric Company, entitled "How to get a Shaft Horsepower for All Purposes with Steam on from 0.75 to 1.00 pound of Oil."

They have entirely begged the question, as they do not inform the readers any details as to 'how' this is to be accomplished. They present the usual theoretical curves for economy, consisting in this case of water rates and oil consumptions for all purposes per shaft horsepower as ordinates and normal shaft horsepower of the vessel as abscissæ, the power varying from approximately 3,000 for the cargo ship to 22,000 for a liner.

Two sets of curves are shown, based on 200 and 250 pounds steam. The article is also illustrated with pictures of the electric driven ship *Independence*.

In the June number of MARINE ENGINEERING AND SHIPPING AGE, furthermore, there is given the specification of a proposed liner of 10,000 shaft horsepower in which the electric drive is proposed to be used, the oil consumption being here stated as 0.85 pound for all purposes per shaft

horsepower, but which figure is also seriously to be questioned.

Thinking that readers of MARINE ENGINEERING AND SHIPPING AGE would be particularly interested in some actual figures obtained in service with the electric drive, in contrast to what has been published for advancing its cause by its advocates, the author presents that which follows:

VESSELS EQUIPPED WITH ELECTRIC DRIVE

The electric drive has now been installed in five vessels belonging to the Shipping Board and has accordingly been given a thorough tryout for this particular service by competent operators. Several battleships in the United States Navy have also been built, employing the electric transmission, and it can be unreservedly stated that the actual results for either type of vessel, which are now available, fall far short of the claims made by its sponsors.

The five Shipping Board vessels referred to are the *Eclipse*, *Independence*, *Archer*, *Victorious* and *Invincible*—the *Independence* being used, as previously stated, to illustrate the article of Messrs. Watson and Thomas. These vessels originally had geared turbine machinery, which proved unsatisfactory in service due to defective gearing.

These vessels have a length of 440 feet between perpendiculars, a beam of 56 feet and draft of 28 feet 7 inches, corresponding to 15,700 tons displacement. The block coefficient, which is 0.68, is unusually fine, and the vessel is accordingly suitable for considerable more speed than the original designed speed of 11 knots, corresponding to 3,000 shaft horsepower with propellers running at 90 revolutions per minute.

The old geared turbine, of General Electric type, con-

*Assistant to chief engineer, The William Cramp and Sons Ship and Engine Building Company, Philadelphia, Pa.

sisted of five stages, operating at 3,600 revolutions per minute and driving through a single pinion double reduction gearing. This turbine was replaced by one of the same general design, but having no reversing wheels and incorporating more stages and other improvements tending to better the thermal efficiency. The later turbine is coupled to a generator rated at 2,360 kilowatts, which supplies three phase current at 2,300 volts to an induction motor rated at 3,000 shaft horsepower, running at 100 revolutions per minute and direct-connected to the original shafting. The blades of the propeller were set to the minimum pitch permissible, for favoring the installation of the motor, which was limited as to diameter and corresponding maximum number of poles that could be employed, the designed revolutions being increased from 90 to 100 revolutions per minute for the 11 knots.

The boilers, which are Scotch with Howden draft, are the original, but superheaters of the Schmidt types were added to give approximately 200 degrees superheat, which, with the more improved design of turbine, was expected to more than counteract the inherent electrical losses, calculated as not over 10 percent, with 80 percent power factor. The latter, however, works out in service about 70 percent, reducing thereby the effective capacity of the generator with a corresponding increase in the I^2R loss due to the wattless current.

PERFORMANCE OF THE ECLIPSE

The first of these vessels to be converted was the *Eclipse*, which was put into service the early part of 1921, and the following data were obtained on the maiden voyage, initiating the new drive:

Total distance, nautical miles	23,611
Mean speed, knots	9.78
Fuel consumption	33.2
Shaft horsepower	2,422
Pounds of oil per shaft horsepower	1.28
Superheat, degrees	198
Boiler pressure, pounds per square inch	214
Chest pressure, pounds per square inch	189

The conclusion reached by the operating company as a result of their experience with the vessel on this voyage, which was arrived at by comparing results with a voyage made before the vessel was changed to electric drive, was that the consumption was increased by 10 percent over that of the original gear drive. Furthermore it was estimated that had the new installation not been equipped with the superheaters the fuel consumption for the electric drive would have been 20 percent more, instead of 10 percent.

Subsequent data obtained from the *Eclipse* in service, and her sister ships, substantially confirm this original unfavorable report, checking very closely the figures obtained on the first voyage of the *Eclipse*. These additional data are shown in Table I, which is made up from the ship's logs, taking the best portions of voyages uninfluenced by adverse weather conditions. The light draft operation of the vessels have been eliminated, and only those portions approximating normal draft conditions have been employed for the general averages shown in the last column. The third column has been inserted to show the effect of draft on speed and economy for the *Independence*. The averages for power and revolutions are arrived at by multiplying same by hours and dividing by total hours. The average power, it will be noted, is 2,396 shaft horsepower, corresponding to 9.92 knots, and which is estimated 10 percent too high for the particular speed. This poor propulsive efficiency is no doubt due to the high turns of the propeller employed to favor the motor, as previously stated.

Comparing the above results with a modern compound marine turbine, using saturated steam, the oil consumption per shaft horsepower is about 30 percent greater for the electric drive using superheated steam. This is based on 1

pound of oil per shaft horsepower, which is easily being realized in service with the first drive with properly coordinated auxiliaries. Using the same degree of superheat the difference in favor of the geared drive would be still more marked, based on the same propulsive efficiency for either drive.

RESULTS WITH ELECTRIC DRIVE ON NAVAL VESSELS

Referring to the results that have been obtained in the Navy with the electric drive, as compared with the geared drive, this is best seen graphically in Fig. 1. Curves "A" and "B" for the battleships *California* and *Tennessee* are seen to have the same general characteristics, though m

Fig. 1.—Comparison of Fuel Consumptions for Electric Drive and Geared Drive, Based on Fraction of Designed Full Power

NOTE—Designed power: battleship, 28,500; scout cruiser, 90,000. Battleships use superheated steam, scout cruiser saturated steam.

chinery was supplied by the two independent electric companies interested in this drive. Curve "C," shows the consumptions for the *Maryland*, and is from the only battleship trial data; showing oil consumptions, published heretofore regarding these vessels. It is to be noted that it has an entirely different characteristic to the other two curves, which is apparently due either to the method of measuring the oil or not including all the auxiliaries in this measurement.

The battleship has two screws and two turbines, while the scout cruiser has four screws and four sets of turbines with a boiler room separating the forward and after independent engine rooms. The scout cruiser is accordingly equivalent to two battleship installations of 45,000 shaft horsepower, and comparable with the present battleship installations of approximately 30,000 shaft horsepower.

Comparing the results of the scout cruiser, shown by curve "D" with the mean of "A" and "B," it will be observed that

TABLE I—PERFORMANCE OF ELECTRIC DRIVEN SHIPS

Voyage Route	Eclipse—Independence—Archer—Victorious					Average for A-B C & D

Pounds fuel per knot						

electric drive requires, on an average, 18 percent more oil per shaft horsepower at full power, 22 percent more at one-half power, and about 90 percent more at one-tenth full power, the latter corresponding approximately to the 10 knots cruising speed of battleships. The scout cruiser is handicapped, furthermore, at full power due to the much higher rate of oil burned per square foot of heating surface, 80 percent of full power of the *Richmond* corresponding to about the normal full power condition of the battleships.

The foregoing, therefore, entirely disproves the most cherished claim of the electrical advocates, which is for higher economy at the reduced or cruising powers.

IMPROVED THERMAL EFFICIENCY OF GEAR DRIVE

The gear drive has certain inherent advantages for improved thermal efficiency, which are not common to the single unit turbine, as necessarily required for coupling to a generator. This is because the gear easily permits of cross compounding of turbine, thus permitting the turbine blading design to approach the ideal conditions for best efficiency.

At approximately one-half power for the cruiser, additional blading is cut in on the forward end of the high pressure turbine, and at one-quarter full power additional blading is put into action. These additional groups of blading carried are designed for maximum efficiency for the particular power and speed at which they are put into operation.

For the cruising speeds of 20 knots and under, a special high speed cruising turbine is employed in each engine room, coupled to the forward end of one of the high pressure turbines through additional gearing. These take the high pressure steam first, exhausting to the forward ends of the high pressure turbines, or the one-quarter power belts. It is for this reason principally that the scout cruiser at one-tenth power actually shows about the same economy as the electrical battleships at full power. The inherent electrical losses, due to the electrical transmission, are given as 10 percent at full power and 20 percent at one-tenth power, which latter is used on one-half the power plant in operation for favoring economy at this speed.

Advocates of the electrical drive have also frequently made other claims besides that of economy, as, for instance, greater liability with freedom of troubles, greater flexibility of drive and simplicity of control than that with the geared turbine arrangement. These are far from being the actual case.

RELATIVE RELIABILITY, FLEXIBILITY AND SIMPLICITY OF THE TWO DRIVES

The William Cramp and Sons Ship and Engine Building Company has built at the present time over a million horsepower of geared turbines without once encountering gear trouble, and other experienced marine builders can testify to the same experience.

As to the cargo ship arrangement having the electric drive, in which there is only one turbine coupled to generator and the one motor driving propeller, if there is trouble with any one of the units, the vessel has to be completely stopped. It is for this reason alone that many experienced shipowners will not consider the electric drive, and for the same reason it is looked on with disfavor by the underwriters. This is not so with the single screw compound geared turbine arrangement, which, in case of damage to either high or low pressure turbine, or their respective pinions, is only one-half as likely to be put entirely out of commission, special piping being provided for permitting either turbine to operate in such a contingency.

The electric drive has other well known disadvantages not common to the steam drive.

OPERATING DEFECTS OF ELECTRIC DRIVE

There are the necessity for having a specially trained engineer force, the liability of short circuits in the windings on account of moisture, the ever present danger with the high voltage employed and the defects of the induction or synchronous motor when used for this service.

At the present time there is a leaning toward the synchronous motor by the electrical experts, due to the induction motor's small air gap, and the all inductive load it imposes on the generator with resultant low power factor.

The synchronous motor, however, requires a more complicated starting gear and is more prone to fall out of step when much overloaded. This latter operating defect is particularly apt to occur in rough weather with the cargo ship, in which the power is small in proportion to the displacement, when there occurs a large variation in the torque. In case of two screws, or more, driven by motors supplied by current from a common alternator, the screws are locked together by the synchronous speed of the generator. This makes for bad maneuvering and it is for this reason that the electrically driven battleships require that both generators be in operation when making port, which is so that each motor will have its independent source of power.

The claim for greater simplicity of control for the electric drive is far from being correct, as shown by the multiplicity of levers, switchboard instruments, rheostats, synchronizing devices, etc.

Other arguments that have been made against the gear drive for advancing the cause of the electric drive are that there are losses due to the astern turbine being rotated idly when going ahead, lack of ability of the astern turbine to develop the full ahead power, and the possibility of trouble with astern blading when high temperature steam is admitted to it suddenly.

The first of these can be dismissed by pointing to the low oil consumption on the scout cruiser and similar vessels.

Applications of Arc Welding to Ship Construction

By E. H. Ewertz*

Those who have been interested in the applications of welding in the above field, have for a long time felt the need of a digest of the available literature and unpublished existing information. This need was recognized by the Electric Arc Welding Committee of the American Bureau of Welding and with its cooperation Mr. E. H. Ewertz has prepared such a review. The report includes a summary of the present applications of welding as compared with riveting, a description of the arc welded ships already in existence and their performance, a review of the repairs to the German liners and the results of tests in England and the United States to demonstrate the adequacy of welding as applied to ship construction, a description of the several designs of welded ships, a comparison of the advantages of welding versus riveting and finally a bibliography. It is needless to say it is the most complete summary available on this subject. It was prepared for the use of the ship designer, the draftsmen and those interested in the application of welding in this field. We trust that those interested will find it useful.

C. A. ADAMS,

Director, American Bureau of Welding

THE design and construction of a ship presents problems of such diversified character and stresses so difficult to define, that, today, the past practice and established rules of various organizations govern the design of a ship both as a whole and as to details. Therefore, new principles of designs and joining parts together are slow at being adopted even though the marine engineer is convinced that by the use of such new designs he would be able to produce a stronger, more serviceable and a less costly ship.

Probably one of the most important new developments in ship construction is based on the use of electric arc welding for joining the various parts together. While such welding has already been applied extensively to the less important parts of a ship, we also have ships where electric arc welding has been used for the more important parts, known as the strength members of the ship. The ship classification societies, by whose rules designers and builders are largely governed, recognizing the merits of electric arc welding as applied to ship construction, have made and are constantly making tests and experiments, enabling them to issue from time to time additional rules, so that today it is possible to use electric arc welding for joining together practically all the parts of a ship.

ORIGINAL IRON SHIP CONSTRUCTION

In the early stages of iron ship construction, before steel manufacturers had conquered the process of rolling shapes, the iron plates forming the sides of a ship were reinforced by framing made up of flat iron bars, fitted on their edges against the ship's sides and held to the plates by means of flat U-bent clips, having rivets in the flanged ends, and this established a T construction between the shell plating and flat bar.

This method of construction was naturally weak in that the connection between the two steel members, the flat bar and the shell plating, was not continuous and, therefore, when angles, channels, bulb angles, Z-bars and other such parts were obtainable, it was perfectly natural that such shapes should be adopted as they permitted riveting in the flange connecting the important members. Thus the bar and the shell produced the same T construction as was found on the earlier ships, but here rivets could be placed close together in the connecting flange of the shape, thereby making a practically continuous connection. However, a still better connection would be obtainable, if the flat bar was joined to the shell plating by welding, making the two members one.

*General manager, Moore Plant, Bethlehem Shipbuilding Corporation, Ltd., Elizabeth, N. J.

Welding by heat is now used extensively in some of the important parts of a ship, such as forgings for stern posts, rudder frames, main engine parts and also in forming off sets and bends in angles as well as in many other details. Welding in some cases may even be found in the ship plating. All such welding has an element of uncertainty connected with it and, therefore, in calculating the strength of such welded parts, a large factor of safety is allowed to protect against failure. Often it is desirable to weld parts that are beyond the capacity of the builder's facilities; then riveting or bolting has to be adopted.

Riveting, also, has its hazards, for heavy locked up stresses are produced in the driving of a rivet and stresses are set up in the plating nearby due to hammering. It is often impossible with the best workmen to obtain fair rivet holes and therefore rivets are frequently driven into odd shaped holes, adding uncertainty to the results obtained. While the testing of rivets is readily performed, it is frequently found in tests of compartments that the water produces an excessive strain on the rivets. Again, rivets having passed all the tests during the ship's construction are sometimes found incapable of standing stresses produced by the ship working in a heavy sea.

The vast amount of skilled labor required to properly form the various members of a ship's structure, to make an punch rivet holes, to bolt together and fair up the various parts, is labor that is little understood by the average engineer. The hazards, however, due to human incapability to produce perfect work are offset by the liberal margin of safety allowed for in the classification rules; therefore, we seldom hear of disaster to a ship due to faulty construction.

WELDING WOULD GIVE IDEAL CONDITION

That further application of welding to ship construction is desirable is evident particularly when we remember that the use of rivets was a method of construction that was made necessary on account of the lack of the proper facilities for further extension of welding of parts, and also because material for parts had to be made to a size suitable for manufacturing and handling. An ideal ship, however, would be made to what might be considered one piece, welding having joined all of the parts into one. But, in the future, as in the past, where the human element enters into the construction, a suitable margin of safety should be allowed for in the calculations and properly trained men as well as the right type of electric arc welding machines and suitable electrodes should be used.

Many tests of various natures have been made to establish

Fig. 1.—Midship Section of Cross-Channel Barge

standards that give equal or better connections between parts than that obtained by riveting or bolting. The Government and ship classification societies have joined with the American Welding Society and other similar bodies in the making of these tests, as well as testing electrical machinery, the material to be welded, and the material to be introduced into the weld—all have been subject to the most careful study and so we now have available data that are in some respects superior to the data used in the old form of construction. Even the problem of the human element has been

given careful consideration, and we believe it is now a lesser problem than the same element is in the old type of construction. Only a small portion of available data in connection with electric welding in ship construction can be given in this paper but further information can be obtained from the many papers referred to in the bibliography; however, before giving these data, we should consider what is now a past—the work of men of vision and determination, who applied electric arc welding in ship construction and, in doing so, gave us the necessary past now to build on.

THE DOROTHY M. GEARY

In 1915, Mr. Geary of the Geary Boiler Works of Ashtabula, Ohio, built a tugboat named the *Dorothy M. Geary*, having a length of 42 feet, a beam of 11 feet, and a depth of 6 feet 6 inches. She was constructed of steel, the shell plating being 3/16 inch, frames 1½ by 1½-inch angles, and bar keel 1 inch by 5 inches. The shell plating was riveted

Fig. 2.—Launch of Quasi-Arc Welded Vessel, A. C. 1320

Fig. 3.—Interior View Showing Quasi-Arc Welded Frames, Floors, Stringer and Shell Plating

Fig. 4.—View Along Deck, A. C. 1320

to the frames and bar keel, but all other joints like ends and edges of plating as well as all other parts were welded by the use of Lincoln electric long arc welding machines, and bare, soft, steel wire.

This tug has been in constant service all the year around and often, in winter, has had to break her way through ice up to 8 inches in thickness. Once she was caught between two large ships and had her side crushed in 18 inches, raising her deck 6 inches. This damage was repaired by using hydraulic jacks to press the sides out to proper places, and neither these extraordinary stresses nor other service conditions have in any way started or cracked the welding.

Fig. 5.—Watertight Bulkhead, Showing Quasi-Arc Welded Seams and Stiffeners

Fig. 6.—Electrically-Welded Coaster Fullagar, Built by Cammell Laird & Company, Ltd., Under the Quasi-Arc Welding Patents

The demand for ships during the great war advanced electric arc welding in a phenomenal way but, due to a lack of proper equipment and also to a lack of trained welders, much work was poorly done making many men prejudiced against this type of welding. Nevertheless, others judging from actual facts continued the process, and in January, 1918, the British Admiralty had constructed at Richborough an all electric welded cross channel towing barge, known as the *AC-1320*. This barge is probably the first all electric welded ship constructed up to that time.

THE AC-1320

The length of this barge between perpendiculars is 125 feet 9 inches, molded breadth 16 feet 4 inches, molded depth

Fig. 7.—Electrically-Welded Ship Fullagar, Floor Plates, Frames and Plating

7 feet 9 inches. She has a deadweight capacity of 200 tons. She has a curved stem with transverse stern and is fitted with two hatchways 42 feet by 10 feet. There are three transverse bulkheads, the fore and aft being watertight. Frames are 2½ inches by 2½ inches by 4 pound angles with floors of 7 inches by 3½ inches by 7 pound angles, and the shell and deck plating is 5/16-inch thick, tapering to ¼ inch at the ends. She is of the usual barge construction having a flat bottom and sides with four strakes of plating on each side, all joggled and lap welded.

During the erection the parts were held together with service bolts 10 inches or more apart, and after the welding was completed the service bolt holes were plugged and

emerged in a satisfactory manner. Last year she was in the service of the Port of Queensborough Development Company, Ltd., whose engineer, Mr. J. W. Bruce, stated after his examination: "This barge has been thoroughly tested by me recently and I find all strake welded laps and joints, frames, web frames, beams and half beams, and all welded parts are in excellent condition. This barge like others of the AC type, has been subjected to very rough treatment and heavy war service during the busy war period at Richborough. She consequently shows definite signs of same, but nevertheless remains in excellent condition and quite tight when loaded. Up to the present it has not been necessary to have any work whatever done to the hull or

Fig. 8.—Midship Section Electrically-Welded Ship Fullagar

welded. All of the welding work was made with quasi-arc welding machines and their special flux covered steel wire was used throughout. Shell plates were joggled to simplify welding operations. All watertight bulkhead connections as well as the bottom plating were continuous welded both inside and out, all other watertight joints were welded continuous on one side and tack welded on the other. On the shell plating the continuous welding was on the outside in all cases. For internal, non-watertight joints and frame construction, tack welding was adopted sufficiently spaced to give a margin of strength over a similar riveted joint.

As is usual in ship construction, framing, bulkheads, and similar parts were assembled and welded on the ground before erection. A very good idea of the construction and appearance of this barge may be obtained by studying Figs. 1 to 8.

The cross channel service gave an excellent opportunity to test out this barge. She had hard usage, having been loaded to capacity with all kinds of war materials, and even unloaded a number of times, but in spite of all this she

deck. The vessel is in good seaworthy condition, and I consider her much stronger than riveted barges."

THE 1,200-TON OIL BARGE HISCO

About the time of building the AC-1320, above referred to, the Tank Shipbuilding Company, Newburgh, N. Y., constructed, under the supervision of Mr. Wm. T. Bonner, the *Hisco*, a 1,200-ton oil barge designed for service in Mexico.

This barge was designed on the Isherwood principle and had a length between perpendiculars of 165 feet 3 inches, a molded breadth of 37 feet 9 inches and a depth of 8 feet 6½ inches. In order to get a direct comparison both from the standpoint of service as well as construction cost, 60 feet of the midship section was welded and the rest of the barge riveted. The shell and deck plating was ¼ inch thick, while the transverse framing members, intercostals and the like were of 5/16-inch plating. Most of the parts were made of plates eliminating many joints found necessary in riveted construction.

After completion, this barge was loaded with a 500-ton

Figs. 9 to 21.—Details of Various Types of Joints Used in Construction of Electrically-Welded Ship Fullagar

cargo, taken to New York where an additional 500 tons of pumping machinery was taken on board. She then left for the 2,500-mile voyage around the Capes to Tampico, where she arrived in due course with hull and cargo in first class condition. After 12 months of service as a bulk oil carrier on the Panuco River, with its rapid currents, heavy winds and tides, it is reported that no repairs have had to be made to this barge.

THE FULLAGAR

In February, 1920, the first all-welded, self-propelled, seagoing vessel, the *Fullagar* was put in commission. This vessel was built by the Cammel-Laird Company, Ltd., Birkenhead, England. She was designed and built as a coast ship, having a length of 150 feet, molded beam 23 feet 9 inches, molded depth 11 feet 6 inches, deadweight capacity 500 tons and cargo capacity 25,200 cubic feet. The propelling machinery is a Cammel-Laird-Fullagar oil engine of 500 brake horsepower at 110 revolutions, having four cylinders 14 inches in diameter by 20 inches stroke. The engine is located in the aft end of ship. The cargo hold is served by two hatches. The fuel oil is carried in side bunkers above the donkey boiler flat. Two masts carry the four derricks which are served by three winches.

The hull is constructed of steel, all in accordance with

Lloyd's requirements. There is used in the construction several types of welded joints. Ends of shell plates are joined together by a continuous butt weld, this welding being backed by a light strap. Plate edges are lapped and have a continuous weld on both edges, one being a heavy, and the other a light weld, and in places, edges are butted and welded as described above for ends of plating. In all cases, watertightness was obtained by a continuous weld, and non-watertight members were tack welded. Figs. 6 to 21 give details of design and construction. All welding was done with Quasi-Arc welding machines and flux covered steel wire.

The engine foundation, which was also entirely all welded has furnished an opportunity for many interesting observations. As reported by Mr. A. T. Wall, the original engine installed and later removed was very much too large for this size of ship and yet did not produce the noticeable vibrations that are generally found on similar ships, with riveted engine foundations. This example shows that better distribution of stresses to all parts of the ship can be obtained with a welded construction.

At the time of trial extremely rough weather was encountered with heavy seas producing severe shocks and strains, which she withstood satisfactorily. Quoting from

Typical Great Lakes Freighter, Built by Great Lakes Engineering Works: Length Overall, 617 Feet; Beam, Molded, 64 Feet; Depth, Molded, 33 Feet

The Trend in Great Lakes Ship Construction

New Types of Ships and Machinery Being Developed—Refinement in Mechanical and Structural Details Is the Tendency in New Freighters Now Under Construction and Contemplated

LARGER ships, higher powers, higher speeds, changes in engine types from steam to Diesel—along what lines is Great Lakes construction progressing? In one form or another all these changes are being tried out but just what influence any one of them will have on either immediate or future building or operating practice remains for the test of the experiments to determine.

To any one coming from the coast the introduction to steamship operation on the Lakes is a revelation to say the least. This, in spite of the fact that it is admitted as a general proposition that ships cannot be operated in any part of the Seven Seas more economically than here. But to gain from observation an insight into the organized methods which make the shipping industry as effective and productive as it is, is an inspiration to any shipping man.

The design, construction and maintenance of ships on the Lakes play a vitally important part in the operating efficiency of shipping, and it is with this phase of the subject in mind that the following notes gathered from visits to various of the shipping and shipbuilding companies are written.

NEW PASSENGER VESSELS UNDER CONSTRUCTION

Under the head of new construction the two passenger vessels now building for the Cleveland and Buffalo Line are perhaps the most outstanding feature on the Lakes at present. These ships when completed will have the distinction of being the largest ever built for inland water transportation as well as having a greater cabin and passenger-carrying capacity than any ships afloat. Originally one of these vessels was intended for turbo-electric drive and designers and

operators became very much interested in the project for its possible effect on future Lake designs. With the exception of the propelling machinery, the two ships would have been identical and, with operating conditions similar, a measure of the effectiveness of turbo-electric drive in comparison with conventional side wheel propulsion in extensive use in lower lake passenger service would have been possible.

It was only after serious consideration of the operating difficulties that the project was dropped, but with the possibility of future adoption of electric drive in new passenger designs. The additional deck space, the increased steadiness of the vessel due to side wheels, the decreased danger to propelling machinery from floating obstructions as well as the necessity for keeping the ships in constant service and the lack of dry dock capacity for these ships finally led to the adoption of side wheel propulsion for both vessels. At some later time complete details of these vessels will be published in MARINE ENGINEERING AND SHIPPING AGE.

DIESEL ELECTRIC VESSELS SOON TO BE PUT IN SERVICE

In another direction progress is being made in the development of craft intended for combined lake, canal and coastwise service as embodied in the two Diesel-electric vessels now nearing completion at the Ashtabula plant of the Great Lakes Engineering Works for the McDougal Terminal Warehouse Company of Cleveland.

These craft are 258 feet length overall, 42 feet beam, 18 feet 9 inches molded depth with decks designed for a bridge clearance of 5 feet above the main deck. They are to be powered with two 375 horsepower Lombard Diesel engines located amidships with General Electric propelling motors

delivering 500 shaft horsepower located in a motor room aft.

The advantages of this design are in the clear hold spaces and with the balance obtained by installing the heavy machinery amidships the vessels can be readily kept on an even keel. The entire operation of the boats, propelling machinery and all will be under the direct control of the captain—the engineer being required only to run the engines.

Since these vessels are to be used for lake, canal and coastwise service for the carriage of perishable cargo they are designed with two refrigerated and two non-refrigerated holds. Instead of carrying water ballast when traveling light, the tanks are arranged so they can be used to carry fuel oil which is intended for discharge at the terminal in Duluth when the vessels take on a cargo. These boats will have a service speed of about 9 miles.

LARGER AND FASTER FREIGHTERS CONTEMPLATED

A demand for larger and faster freighters is probably not far distant, for inquiries have been made by at least one of the Lakes shipping companies for ships 633 feet long, 64 feet or 66 feet beam and 33 feet molded depth. Estimates have also been worked out for installing propelling engines delivering 3,300 horsepower in one of the 630-foot type freighters instead of 2,600 horsepower.

The use of surface condensers has been contemplated as a means of eliminating boiler trouble caused by dirty harbor water when used for feed. This would avoid the present necessity of carrying large quantities of fresh water in the deep tanks for harbor service.

The possibility of adopting Diesel engines for propulsion or of equipping boilers with oil burners for Lake service seems remote, although in isolated cases they have been used.

IMPROVEMENT IN SCOTCH BOILERS

Scotch boilers being installed at the Great Lakes Engineering Works in a 12,000-ton freighter, soon to be put in service, indicate as much as any other item of equipment the tendency of the Lakes towards refinement of construction details as the most direct means for creating savings in productive service time and reliability of equipment. These boilers, which are 13 feet 6 inches in diameter by 11 feet 2 inches long with 3 Morison corrugated furnaces, are made with shells $1\frac{1}{4}$ inches thick in one strake without middle circumferential seam and having the front and back heads flanged from single $1\frac{1}{8}$ -inch plates, thus eliminating all doubling plates on these heads. With this construction, having the required factor of safety specified by the Steamboat Inspection Service, the allowable working pressure is 180 pounds.

New Ballast Pumping Systems Developed

L OADING and unloading speeds of Lake freighters and the rapid turn around in port are difficult to realize without actually observing the performance, but it has been found by certain operating companies that still greater time saving can be accomplished through improvements in ballast pumping arrangements and these are being incorporated in new vessels under construction.

On a 12,000-ton freighter recently launched, for example, the side and bottom ballast tanks are built up as a number of independent units, having connections through valves and manifolds with each other. Individual tank valves, of the 8-inch angle type, throwing one tank into direct connection with another, are controlled from the ship's deck while manifolds and valves, controlling the pumping as well as pumping equipment, are located aft in the engine room according to usual practice, with certain additional controls making it possible to pump any section of the tank system as desired.

The outstanding feature of this system is the time saving made possible by the ability to pump the side ballast tanks independently of the bottom tanks, while the bottom tanks are being filled by gravity, so that the time required for ballasting the ship is materially reduced. This time saving, however, is only one of several advantages claimed for the system.

If for any reason it is desired to use the system as a unit all tank valves can be opened and the tanks completely interconnected. From the standpoint of safety the independent tanks may be used to close off any section of the hull in case of collision or wreckage of the side or bottom of the vessel where the plating has been damaged. That this is of real value every operator probably realizes, for instances of the larger vessels in Lake service dragging in the locks or over bars are not at all infrequent. In such cases the closed tanks act as watertight compartments. Accurate control of ballast, tending to promote stability and fuel economy, is also credited to the system.

The machinery complications incident to a ballast system of this kind have been carefully considered and, although the additional weight of valves and piping together with the maintenance of the system have a bearing on the economic value of it, the greatest speed and safety apparently far overbalance these factors.

New Bearing Metal Introduced to Marine Service

B EARING troubles are by no means uncommon in marine service and any steps that can be taken to prevent burned out bearings or scored shafts or pins, causing expensive delays, deserve a careful investigation. One of the prominent shipbuilding concerns on the Lakes having in charge the construction of a great many of the largest freighters seems to have overcome bearing difficulties on its ships through the use of a new bearing metal adapted from stationary practice. This metal seems to be more or less proof against the usual difficulties experienced in bearings which result especially from over heating, lack of lubrication and other abnormal conditions.

PROPERTIES OF NEW BEARING METAL

This metal is a pure alloy consisting of copper and lead and is poured into the bearings in a molten state in much the same manner as babbitt. It is said to have a tensile strength of 11,000 pounds per square inch and three times the compressive stress of babbitt, while it has approximately the same combination of friction and bearing qualities as the latter metal. It is, however, slightly harder to work. So far it has been used in the connecting rod bearings and for similar service in various parts of the machinery.

The first trial given this metal aboardship was in the connecting rod bearings. One crank pin bearing was slack and pounded hard all the way on a trip from Detroit to Duluth. On inspection, after the trip, the bearing was apparently no worse for the pounding and ran through the season.

On the first trip this spring one of the oil lines on this engine broke while the ship was far out in the Lake, so that the crank pin was getting no lubricant at all. The bearings became too hot to cool with water. In spite of this, the engine was driven for fifteen hours without crank pin lubrication until she reached port, where the bearing was overhauled. With the exception of a certain amount of lead which the heat had brought to the surface, and which was scraped off, the bearings were apparently all right. The pin was smoothed up with an oil stone. Since this slight overhauling the engine has been in service without further trouble.

Increase in Oil Freight Rates Causes Foreign Shipyards to Receive Numerous Inquiries for Tankers

General Adoption of Diesels for Motive Power Predicted

Foreign Taxation of Shipping, Delays in Home Ports and Bill to Regulate Storage of Petroleum Troubling English Shipowners

By W. H. Wendon*

THE phenomenal advance in oil freights—the rates at the latest writing are three-fold those ruling at the beginning of the year—is a natural result of the extraordinary demand for oil tank steamers, and it is not surprising, therefore, that tenders are becoming more and more frequent in connection with vessels of this type. The construction of an oil tanker of 12,000 tons, to be fitted with Diesel engines, is contemplated, inquiries are circulating to build a 10,000-ton oil tanker with steam engines, while another inquiry relates to a 10,000-ton oil tanker to carry molasses and fitted with Diesels.

On the continent, the French Government is understood to be seeking tenders from French shipbuilders for the construction of an oil tanker of about 9,000 tons, and the Rotterdam Dry Dock Company has received a contract to build a tanker of 6,000 tons.

The whole question of the motor-vessel is thus once more on the forefront. The perseverance of the pioneers who bore the brunt of the experimental contracts would seem to have been justified, for it is generally accepted that the internal combustion engine is now a commercial proposition. One well-known and successful United Kingdom shipowner, who has for some time been regarding, from all angles, the question of adopting Diesels, is now convinced that the Diesel engine is the motive power of the future, and in support of his assertion, he has asked for tenders for the construction of a vessel to carry between 7,500 and 8,000 tons. This shipowner furthermore considers that the general adoption of the internal combustion engine will be much quicker than was the transit from sail to steam, or from the compound engine to the triple expansion engine.

FRENCH SHIPOWNERS INTERESTED

A further illustration of the increased attention which the internal combustion engine is receiving at the hands of shipowners generally is afforded in the case of France, where hitherto the engine has been practically ignored. Only one Diesel engine vessel—a boat of 10,000 tons deadweight—has, in fact, been ordered in France since the end of the war. It is nearing completion at Nantes, but, no doubt as a result of the pioneer operations of shipowners of other countries with this type of vessel, the passing interest is developing into something more tangible. One leading French shipping company, the Messageries Maritimes, is understood to be contemplating the placing of an order for the construction of a 10,500-ton motor-liner, to be built for passenger service between Marseilles and the Eastern Mediterranean. In view of the increased interest in the type, it is not too much to expect that other French shipowners will at least make inquiries as to the possibilities of the internal combustion engine as an economical motive power for passenger and cargo ships.

The imposition of taxation on shipping at home and abroad is again a leading question in United Kingdom ship-

*Our British Correspondent.

ping circles. The subject has from time to time been debated at great length for many months past, but, at this writing, a solution of the problem seems as far off as ever. The offer of the United States Government to exempt from taxation the ships of any nation which similarly exempts United States shipping from taxation in her ports has long been acknowledged by shipping experts on this side of the Atlantic as a highly valuable one, and, in view of the national financial proposals now being dealt with in Parliament, the shipping "powers-that-be" deem it an opportune moment to repeat emphatically that the offer of the United States Government should be accepted.

Sir Frederick Lewis reminds us, that during the past few years it has become a more and more common practice for foreign Governments to tax the earnings of ships touching at their ports. Moreover, in each country an entirely different method of procedure is adopted for calculating such taxation. Sir Frederick, who is a confirmed supporter of the United States proposal in this important matter, points out that owing to the extraordinarily peculiar practice of some countries in looking upon freights as profits, and taxing those freights as though they were profits, it very often results that shipowners pay income tax upon a voyage which may, in fact, have resulted in a loss.

ENGLAND GREATEST LOSER

Then again, it has to be borne in mind that, owing to the fact that Great Britain has far more tonnage engaged in the overseas trade than any other nation, any general extension of the practice, if carried to its logical conclusion, would obviously result in a greater amount being paid out in taxation to foreign countries than Great Britain would receive from taxation imposed upon foreign shipping. Sir Frederick Lewis believes that, from the nation's point of view, it would be an advantage that the offer of the United States Government be accepted.

British shipowners would also welcome a step which would both relieve them of the irksome duty of filling up complicated and voluminous returns to the United States tax authorities, and at the same time relieve them from the liability for taxation in this particular direction. In a word, British shipowners would welcome it if only as a first step towards the larger policy of complete immunity of shipping from international taxation. What view the British Government will take remains, of course, to be seen.

DELAYS IN PORT

Shipowners in the British Isles are experiencing an anxious time in regard to a matter over which, unfortunately for them, they have very little control, and that is in respect of delays to vessels while in port. Concrete instances, involving serious financial losses, may be cited as illustrations of the delays which shipowners are incurring in British ports as compared with ports abroad.

Thus, a vessel under the management of a leading firm of

shipowners loaded a coal cargo in the United States. She arrived in port at 8 o'clock on a Sunday morning and left again at 6 o'clock on the following Tuesday morning, having loaded 8,800 tons of cargo and bunker coal. This particular instance, moreover, occurred during a holiday week-end. During the same week a steamer of about like capacity loaded a cargo of coal at Cardiff. The vessel, after having waited nine days to get into berth, occupied eight days in loading and bunkering, and did not sail until the ninth day.

Such delays, unfortunately, are not confined to Cardiff, or even to South Wales as a whole; they are authoritatively stated to be typical of a great many other British ports when they are compared with foreign ports which have specialized in the handling of a particular description of cargo. Mr. J. Denholm, a leading Scottish shipowner, is my authority for stating that while, in pre-war days, a boat of 7,000 or 8,000 tons could be loaded in eight to ten days, now a vessel is seldom loaded within three weeks, adding materially, of course, to the cost of working.

TO REGULATE STORAGE OF PETROLEUM

The Shipowners' Parliamentary Committee, a body whose members are prominently identified with the Chamber of Shipping of the United Kingdom, have taken up a matter which is of great urgency from the point of view of British shipowners. The trouble revolves round a Bill to amend the Petroleum Acts, and under which a license will have to be obtained from a Secretary of State before petroleum spirit exceeding 1,000 tons or petroleum 5,000 tons can be stored.

The measure has been instituted, presumably to ensure that, in the event of another war, the contents of the storage accommodation will be, as far as is humanly possible, immune from attack. The whole point is that naval and military exigencies are apparently to be placed before those of commerce. At present the dock and harbor authorities grant applications for the erection of storage tanks, and it has been possible in the past for work to be commenced on the installation within a few days of the request being made. But, with the decision of a Government Department to be awaited, serious delay will be occasioned, added to which the storage tanks may have to be erected in positions where the danger of attack by aeroplane or otherwise may be minimized, with the result that the cost of installation and pipage might be gravely prejudicial to the trading interests of those concerned.

It is realized, of course, that there should be national reserves of petroleum in protected positions, but it is maintained that such needs should be arranged for by the Government irrespective of commercial requirements. The Shipowners' Parliamentary Committee have therefore decided to oppose the Bill, they being of opinion that it introduces the unsound and disastrous principle that commercial requirements should be subordinated to the naval and military exigencies, and they view with apprehension the attempt to legislate for commerce on the basis of a state of war.

They hold that the removal of commercial stores of petroleum in accordance with defence needs will cause the gravest expense and inconvenience to shipping, and will throw a heavy burden on the consumers of such stores by increasing the cost needed to cover the economic waste which will be caused, in addition to the extra capital charges which must necessarily be incurred by private enterprise in order to provide installations of a capacity capable of satisfying the requirements of defence. In brief, the contention of the Shipowners' Parliamentary Committee is that the necessary reserves should be created by, and maintained under, the control of the Defence Ministries and at the national cost, and that such national stores should be entirely separate from the commercial, thus avoiding the dislocation of private interests.

TRAINING CADETS

The question of apprentices for the sea has been taken up with vigor by Sir William Reardon-Smith (head of the Reardon-Smith Lines), who commenced his sea career at the age of twelve and spent some 33 years at sea, both in sailing-vessels and later in steamers, for twenty years of which period he was in command. I gather that he decided, when starting in business as a shipowner, to carry apprentices in all the steamers owned or managed by him, and to ensure that they obtained a practical knowledge of navigation, combined with a thorough training for sea life during their term of apprenticeship.

The number of apprentices carried in Sir William Reardon-Smith's steamers ranges from four in the smaller vessels to eight in the larger ones—a total of about 200 apprentices for the fleet. The apprentices' accommodation is in the midship house, near the captain's and officers' quarters. The indentures signed are for a period of four years, and wages paid to the apprentices are £8 for the first year, £9 for the second, £11 for the third and £12 for the fourth year, making a total of £40 for the period of apprenticeship. The more promising boys, as they approach the end of their apprenticeship, act as third mates, and on satisfactory completion of their indentures they receive a cash bonus to help defray the expenses of studying for examination as second mate.

Some time ago Sir W. R. Smith's firm subscribed £2,000 as the nucleus of a fund for a nautical school at Cardiff for the training of young boys for the sea, and the fund was subsequently augmented to £20,000. Boys are admitted at the age of thirteen, and the duration of the school course is three years. The first two years are of a preparatory character, and the final year (the cadet course) is devoted to training on lines approved by the Board of Trade. The subjects taught during the two years' preparatory course are English, mathematics, science, geography, with its practical application, physical exercises and manual work, signaling, etc. During the third and last year the instruction is mainly confined to such subjects as have a distinct bearing on the future career of the boys. The cadet course (third year) is recognized for six months' remission of sea service. My object in referring to the foregoing at some length is to afford United States shipowners an idea of the methods adopted on this side of the Atlantic to ensure, for the coming years, an adequate supply of young but efficient officers and men.

MAY REQUIRE DOCUMENTS IN TURKISH

A mild sensation has been created in shipping circles here by the intimation that the Turkish authorities are now insisting that all bills of lading, passenger tickets and masters' receipts for vessels loading in Turkish ports shall be worded exclusively in Turkish. The regulation is applied equally whether a vessel is loading for a foreign or a Turkish destination, and whether a passenger has booked to a Turkish destination or otherwise. Orders will also be issued to the master of a vessel in Turkish, and therefore, probably, in a language he does not understand. A vigorous protest against the action of the Turkish authorities in prohibiting documents in any other language than their own will doubtless be registered, for it is easy to imagine what chaos would ensue if every country adopted a similar attitude. Every vessel would have to carry an official interpreter.

MARINE WORK of all classes, reaching a total of \$220,013,463, has been reported by MARINE ENGINEERING AND SHIPPING AGE as contemplated and contracted for during the first half of 1923. Vessel construction and repair work contemplated and awarded during the second quarter reached a total of \$38,459,801; port improvement work, contemplated and awarded, \$91,347,628; making a total of \$129,807,429 as against \$90,206,034 for the first quarter.

Motorship Dalgoma

The Largest Two Cycle Engined Motorship

Sulzer Two Cycle Diesel Engines of 3,200 Brake Horsepower Built in Scotland for Motorship Dalgoma

By Our Special London Correspondent

IN Europe, the completion of cargo and even passenger ships equipped with four cycle Diesel engines is becoming so common that very little notice is taken of every new vessel of this class that is placed in commission. The number of two cycle engined craft is still, however, very small, so that special attention is paid by engineers, ship-owners and shipbuilders to boats in which propelling machinery operating on this principle is fitted.

Probably one of the most interesting ships of the class is the *Dalgoma* which sailed on her maiden voyage to the East early in June. She was built to the order of the British India Steam Navigation Company, which possesses more steamers than any other British firm, and is one of a series of motor craft constructed for this concern, the majority of which however are equipped with four cycle engines.

ENGINES BUILT IN SCOTLAND

In the *Dalgoma* are installed the biggest motors of the Sulzer two cycle type that have yet been fitted on a ship, and in view of the fact that half a dozen of the leading British marine engine builders have taken up a license for the manufacture of the Sulzer Diesel engine, it is specially noteworthy that the machinery of this ship was built by a Scottish firm, Messrs. Alexander Stephen and Sons. The only other Sulzer engined ship constructed in Great Britain was provided with machinery by the Swiss manufacturers so that the *Dalgoma* represents something of a new departure in British shipbuilding.

She is 448 feet in length overall with a length between perpendiculars of 430 feet, the beam being 54 feet 6 inches,

the depth 32 feet 6 inches, and the deadweight, including fuel, about 9,300 tons.

The two engines are each designed to run in the ship at 85 revolutions per minute at which speed the total power developed is 3,200 brake horsepower or about 4,300 indicated horsepower (2,150 indicated horsepower for each engine). It may be added, however, that exactly similar engines have been built for installation in another ship, but the speed has been increased to 100 revolutions per minute giving an output of 2,000 brake horsepower. Bearing this in mind, the fact that the total length of the engine room is only 48 feet is worthy of consideration in any comparisons that are made between two and four cycle plants. It is true that an additional space is required in the form of a recess at the after end of the engine room for the turbo blowers, but this is comparatively small.

This engine has four cylinders, whereas a corresponding four cycle motor would necessarily have six. The cylinders are 680 millimeters bore with a stroke of 1,100 millimeters and it may be remarked that with the engines running at normal speed the mean indicated pressure in the cylinders varies between 90 and 100 pounds per square inch. The mean effective pressure referred to brake horsepower would therefore be in the neighborhood of 73 pounds per square inch which is not excessive.

CONTROL STATION AT TOP OF CYLINDERS

An unusual feature of the installation lies in the location of the control station at the level of the top of the cylinders. The reason for the employment of this system is that the whole of the control gear, valve mechanism, fuel

Control Station at Tops of Cylinders

The Engine Room at Floor Level

pumps and, in fact, the most important parts of the machinery are at the top of the engine and not at the bottom. On the other hand there is a large amount of auxiliary machinery on the engine room floor, so that it is questionable whether there is much to be gained either way.

In general design, the engines are of the well-known Sulzer type and as they have been so frequently described it is scarcely necessary to give further detailed particulars. In one point, however, they are unusual in the adoption of turbo scavenging pumps, instead of having the normal piston pumps driven by a crank on the main engine crankshaft. This is only the second ship in which such an arrangement has been fitted and is the first British vessel where it is employed.

As previously mentioned, there are two turbo blowers arranged in a recess at the after end of the engine room. Both

of these blowers deliver into one large pipe, from which branches are taken to each of the propelling engines. The turbo blowers are driven by electric motors of about 230 brake horsepower running at the high speed of 2,750 revolutions per minute. Air is drawn down from the deck to the blowers and is discharged to the main trunk at a pressure of about 2 pounds per square inch above atmospheric pressure.

The output of these blowers is high, being about 17,000 cubic feet per minute at a pressure of 1.8 pounds per square inch. It was found on actual trials that the power needed from the electric motor was in the neighborhood of 175 brake horsepower, one set, of course, supplying all the air necessary for the scavenging of both main engines. This power is equivalent to about 5 percent of the total engine output and for given cylinder dimensions it will be seen that this amount is virtually added to the shaft

1,600 Brake Horsepower Stephen-Sulzer Engine

horsepower developed, by detaching the scavenging pumps from the propelling motors.

The arrangement of auxiliary machinery differs to a considerable extent from that usually adopted in four cycle engined vessels. There are only two electric generators, in spite of the fact that all auxiliaries are electrically operated. These necessarily have to be of large size and they comprise 410 brake horsepower four cylinder two cycle Sulzer engines each driving a dynamo of 260 kilowatts at 220 volts.

In view of an increasing tendency on the part of some builders to utilize high speed Diesel machinery for auxiliary purposes, it may be stated that these engines run at only 200 revolutions per minute. There has lately been some trouble experienced with auxiliary machinery mainly on account of the high speed and it is by no means unlikely that there will be a gradual reversion to the relatively low speed auxiliary in the future in spite of its higher cost and the additional weight and space occupied.

It is somewhat surprising to find two electrically driven auxiliary compressors installed in the engine room. As is well known, in most ships, one auxiliary is ample for all purposes. The installation of an additional set purely for

safety in the case of a very remote emergency hardly seems to be warranted under present day conditions. Each of these compressors is driven by a 150 brake horsepower electric motor. They are, of course, not required in normal circumstances and even when entering and leaving port only one is needed for at most an hour or two.

The propelling engines drive their own three-stage air compressors and, in addition, a main lubricating pump, a bilge pump and a small vertical high pressure pump for supplying lubricating oil at about 250 pounds per square inch to the crosshead pins. The jacket and piston cooling pumps are electrically driven, only one of the latter being provided but there are two piston cooling pumps, delivering water to the pistons at about 25 pounds per square inch. These pumps are of the centrifugal type and in order to ensure that they shall always run drowned, they are supplied with fresh water from a large tank located high up in the engine room. The piston cooling water, after being forced through the pistons by the centrifugal pump, drops into a tank below the engine room floor, when it is picked up by a separate plunger pump and thus raised to the gravity feed tank which also acts as a cooling pump. Sea water cools the jackets.

Scout Cruiser Detroit Completes Official Trials

**Vessel Built by Bethlehem Shipbuilding Corporation, Ltd.,
Equipped with Turbines Developing 100,000 Shaft Horsepower**

THE United States scout cruiser *Detroit*, which has just completed exhaustive trials off the coast of Maine, has established a record by developing the highest power ever attained by any vessel constructed in the United States. The *Detroit* was built for the United States Navy by the

Bethlehem Shipbuilding Corporation, Ltd., at its Fore River Plant, Quincy, Mass.

The vessel is in effect a very fast and powerful destroyer, having a length of 555 feet, a breadth of 55 feet and a normal load displacement of 7,200 tons. She carries twelve 6-inch

United States Scout Cruiser Detroit Undergoing Official Trials

rapid fire guns of the very latest model, four 3-inch anti-aircraft guns capable of firing into the air at any angle up to 90 degrees, ten torpedo tubes fitted to fire the latest model 21-inch long range torpedoes, and more than two hundred mines which can be launched over her stern and laid in a very few minutes while running at full speed.

The vessel is fitted to carry airplanes which can be launched from revolving catapults while running with, against or across the wind; also with high power radio apparatus, wireless telephones, submarine signalling apparatus, electric steering gear, laundry, workshop, hospital, etc.; in fact, she is in all respects the last word in design, construction, equipment and armament that lessons of the late world war have shown to be essential for carrying out duty to which she would be assigned in time of war.

Power for lighting the vessel and for operating the searchlights, wireless and various other electric-driven auxiliaries is generated by four 100-kilowatt turbo-generator sets.

PROPELLING MACHINERY DEVELOPS 100,000 HORSEPOWER

The propelling machinery of the *Detroit*, designed and constructed throughout by the Bethlehem Shipbuilding Corporation, Ltd., developed 100,000 shaft horsepower on trials, which is sufficient to drive the vessel through the seas at a speed of 35 knots, or nearly 41 land miles per hour. This speed would take the vessel from New York to Liverpool in 80 hours as compared with about 120 hours required for the fastest passenger liner now afloat.

Describing briefly the main propelling machinery, the ves-

sel is fitted with twelve oil-fired watertube express type boilers, three being located in each of the four watertight compartments, and operated under forced draft. There are two watertight engine room compartments amidships in which are located the twelve powerful Curtis-type marine steam turbines. These turbines operate at a speed of 2,500 revolutions per minute which is reduced, through reduction gears on each of the four propeller shafts, to 400 revolutions per minute. The excellent economy obtained in connection with the oil fuel consumption as compared with that of the older coal burning installation, is quite remarkable.

Some idea of the enormous power and capacity of the propulsion machinery installed on the *Detroit* may be obtained from the following figures:

At full speed, the shaft horsepower developed is approximately three times as much as fitted to the recent battleships. Oil fuel is consumed at full speed at the rate of 100,000 pounds per hour, which requires 624,000 cubic feet of air per minute to effect combustion.

The twelve express type boilers contain 65 miles of steel tubes, in which steam is generated at the rate of 1,500,000 pounds per hour at a pressure of 265 pounds per square inch.

The main turbines are fitted with approximately 32,000 blades, some of which rotate at a speed of eight miles per minute.

Four main condensers, located in the engine rooms, require about 70,000,000 pounds of sea water per hour to condense the 1,200,000 pounds of steam from the main turbines.

Milwaukee Makes 36 Knots

THE *Milwaukee*, second of the new type scout cruisers built by the Todd Shipyards Corporation, developed a speed of 36 knots, equal to 41.4 statute miles, her engines developing 97,000 shaft horsepower on her recent trials. She is the fastest vessel of her type in the world.

Admiral J. K. Robison, chief of the Bureau of Steam Engineering, pronounced the trial as highly successful and Captain W. C. Asserson, U. S. N., commander of the *Milwaukee*, said he was delighted with the performance of his new command.

At 8.45 a. m., the *Milwaukee* left her pier in the Todd yards at Tacoma, Wash., and swung into the stream at quarter speed. After rounding Brown's Point, speed was increased until the cruiser logged 21.2 knots, the average maintained until she reached Port Townsend. Off Marrowstone Light, where the presence of the Pacific is first manifest, the beginning of her real speed trials commenced.

Slowly at first, the long, narrow cruiser nosed her way out into the straits, cutting through the water at a constantly increasing speed until she was reeling off 35.2 knots. The wind velocity at this speed was so great that some of the official observers were almost blown bodily against rails and bulkheads.

After nearly an hour's run, during which the same high speed was maintained while the *Milwaukee* raced down the straits, all but one of the remaining steam nozzles were turned on, and before Port Angeles was astern, the cruiser was tearing through the water at the record-breaking speed, for a vessel of her type, of a trifle faster than 36 knots. The cruiser's bow was kept headed toward the mouth of the straits until Race Rocks were astern and then put about and headed for home.

The *Omaha*, first of the Todd-built scout cruisers, recently clipped 20 hours and 56 minutes off the record for the run between Honolulu and San Francisco. She steamed the distance of 2,103 miles in 75 hours and 11 minutes, the previous record, held by the steamship *H. F. Alexander*, was 100 hours and 31 minutes.

Care and Upkeep of Marine Watertube Boilers

Maximum Efficiency Can Only Be Obtained by Keeping the Power Plant in First Class Physical Condition

By A. Ross Mackay*

IN the era of prosperity immediately following the war it was sufficient that a vessel be operated without excessive cost in overhauling or repairs, but in these days, when freight rates have dropped to a point at which operating costs are barely covered, rigid economy must be practiced, if the vessel is to continue in service. As the boilers are the heart of the ship, it is most important that they be operated to give the greatest efficiency, which can only be accomplished by keeping them in first class physical condition.

The handling of the fires or oil burners to give the lowest temperature of funnel gases and the least amount of excess air commensurate with complete combustion; heating surfaces kept free from heavy soot deposits by the periodical use of the steam lance or blowers; the prevention of corrosion, pitting, scale formation and tube loss by careful observation of the feed and boiler water, are all recognized as good practice aboardship, whether the boilers be of Scotch or watertube type. To a certain extent, also, the practices that govern the inspection, overhaul and repair of Scotch boilers are applicable to the watertube boiler. Any engineer who has operated an installation of Scotch boilers efficiently and economically should be all the better able to operate a watertube installation, when he has mastered the details of construction of the boilers and the best methods to be followed in keeping them in condition for such operation.

EXTERNAL INSPECTION

In inspecting and overhauling watertube boilers the engineer will, of course, be governed by the length of the stay in port and the time that can be accordingly given to this most important duty. If the stay in port is to be brief, requiring that the boilers shall be held all ready for getting the fires under way, a close inspection can be made of the boilers externally. The condition of the tile and insulating material between the side generating tubes and casing plates can be tested for tightness by light blows of the knuckles on the plates, a hollow sound indicating, of course, an air space which will require filling at the first available opportunity. In similar manner the insulation of the furnace walls can be tested and inspection made of the bolts securing the walls. All tube doors, inspection doors and cleaning doors can be gone over, to see that they fit against their frames and that the latches are so adjusted that they hold the doors tightly closed, preventing any air leakage from this source. The straps covering the joints in the casing plates should also be examined for the same reason. For that matter, the casings at these points can be tested with a torch or lighted candle when the boiler is in use, air leaks being temporarily calked with asbestos putty or other suitable material.

In the event that the boilers cannot be emptied, and that, accordingly, the internal condition of the tubes, headers and drums cannot be noted, a very thorough inspection can be made of the fire side of the heating surfaces, the furnaces and baffles, in addition to the casing inspection aforementioned. In this condition, also, the boiler can be inspected for any leakage at the tube or nipple seats.

CONSULT DRAWINGS BEFORE MAKING CHANGES

Too much care cannot be exercised in the inspection and overhaul of the furnace, not only for the reason that a defective wall will affect the combustion, and consequently the boiler efficiency, but that the boiler structure and casings may be seriously damaged, if exposed to the intense heat of the furnace. As the boiler manufacturer usually furnishes each vessel with a very complete set of drawings, it would be well to make a thorough study of the furnace design, noting the provision made for the expansion of the brickwork, the method of securing the brick in place and the different materials used to insulate the walls and floor. Most of us are prone to experiment—especially when some one else bears the expense—and the marine engineer is no exception. It should be borne in mind, however, that the design of the furnace, and the use of certain materials in the design, are the outcome of many years of close application to the science of burning coal and oil efficiently, and that therefore no change in design or material should be made without careful consideration of the possible consequences.

If any departure from the given design is contemplated, or if there is any doubt in the mind of the operator as to the condition of the furnaces, the matter should be taken up with the manufacturers, who will undoubtedly give him the benefit of their knowledge and experience. In this connection it might be stated that at least one watertube boiler company maintains a trained corps of visiting engineers who board the vessels equipped with their boilers, make inspection of the boilers and discuss with the operating personnel their care and upkeep, this service being free of charge. Needless to say, such service is not altogether in the interest of the operator, as the manufacturers are thus assured that their product is not only giving perfect satisfaction, but that it is receiving the care and attention that should be accorded any valuable piece of equipment.

BAFFLES

A careful inspection should be made of all baffles, to see that they are in correct position and securely fastened. If the boilers are of Babcock and Wilcox type, particular attention should be given the baffle forming the furnace roof. This baffle is of molded tile fitted to rest on the row of tubes directly over the furnace. It extends from the front headers to the rear vertical baffle and directs the furnace gases to the first pass, between the vertical baffle and the rear headers. Any leakage in this horizontal baffle will allow the gases to short circuit into the last pass, thence to the boiler uptake. As the condition of this baffle can be observed from the furnace and the cleaning doors at the boiler sides, and, in the case of the latter, when the boiler is under steam, there is no excuse for its being operated in defective condition, once the defect has been noted.

As the tubes over the furnace are really part of the furnace, it follows that they should be inspected in conjunction with the furnace. These tubes are subjected to the greatest temperatures, and are also subject to destruction from floating matter lodging within their interior. They should be carefully examined for distortion and "blisters," especially the latter. These blisters are generally caused by the lodging of loose scale in the tube and the building up, over the scale, of matter usually held in suspension, until a point is reached at which the tube becomes overheated directly under the scale and, due to the pressure within, bulges outward towards the furnaces.

*Engineer, Babcock & Wilcox Company, New York.

BLISTERS

It often happens that on internal inspection the blistered tube shows no sign of scale or other deposit at the point of failure, so the blister is attributed to some other cause. In reasoning thus, however, the point is entirely overlooked that the movement of the wall of the tube disturbs the deposit, which is swept from the tube by the violent action of the water and steam within the tube, leaving no indication of its late presence. In somewhat the same manner tubes that have blistered from oil deposit very often show no sign of oil locally.

The question naturally arises: When is a blistered tube due for renewal? On this point authorities and services differ, so the operator will have to be guided largely by his own or others' experience in this connection. In certain services the slightest blister or bulge is sufficient to condemn a tube, while in others the operator uses his own good judgment as to whether or not the wall of the tube has been sufficiently injured to warrant renewal. There are many factors to be considered, such as the number of tubes blistered and the amount of new tubes available, the fact that the boiler will have to be emptied to permit of the renewal, the length of the stay in port or the voyage ahead. In case of any doubt, however, the tubes should be renewed; otherwise it may be necessary to renew the tube at sea and under extreme difficulty.

INSPECTION OF TUBES

In inspecting the headers and tubes internally it is advisable to remove the entire lower row of handhole caps in the front and rear headers, so that a thorough examination can be made of the entire row, the mud drum and mud drum nipples. The condition of these tubes will determine whether or not the caps to the entire row directly over it should also be removed, and even the row next above that, all according to just what must be done in the way of cleaning the inner surfaces. For inspection only, it is sufficient to remove a handhole cap here and there in each horizontal row, thus avoiding the needless waste of gaskets.

Tubes can generally be cleaned by the use of the brushes or expanding spoon-type scrapers furnished by the manufacturers, but if hard scale has formed, usually in the lower rows only, turbinizing will be necessary. During this operation the turbine cleaner should not be allowed to remain for any length of time at one spot in the tube, otherwise the surface of the tube may be damaged, rendering it more liable to corrosion. Care must also be taken that the tubes, headers and mud drum are thoroughly cleaned out after turbinizing, to avoid the danger from floating scale described above.

A THOROUGH CLEANING METHOD

Should the boiler be badly scaled and time permit, a thorough cleaning out may be given by the following method:

Drain the boiler, close it up, with the exception of a lower handhole, through which pour about 30 gallons of kerosene into the mud drum. Put the handhole cap in place and open the air cock on the steam drum. Through a $\frac{3}{4}$ -inch pipe, tapped into a special handhole cap in the end of the mud drum, allow a steam jet to blow into the boiler until such time as the condensate has risen well over boiler working level, or about three-quarter glass, which should take from 36 to 48 hours, when the steam can be shut off, the pressure relieved and the boiler drained. Just as soon as possible the handhole plates should be removed and the tubes thoroughly scraped and washed out. It will be found that the scale will come away clean from the metal surfaces. Vaporizing the boiler by this method has been found very effective, not only in loosening scale but in giving the boiler a thorough cleaning out.

The inspection of the internal fittings of the steam drum scarcely needs mention, beyond perhaps a word of caution

with regard to the zinc plates. These plates are usually suspended in baskets of perforated sheet metal, thus making provision for the reception of the disintegrated zincs. Should these baskets get adrift from their fastenings, or should they be incorrectly replaced after work has been performed in the drum, portions of disintegrated zinc are apt to pass through the downtake nipples into the sections, causing tube losses.

PITTING

The steam drum should be wire brushed and wiped out with kerosene to enable a proper inspection to be made for any sign of pitting or other action. In the event that pitting is discovered, which generally occurs at the working water level where the nipples and tubes enter the drum, the pitted portions should be cleaned down to bare metal and the entire internal surface of the drum given a coat of French zinc. Pitted tubes can also be treated with a thin coat of French zinc and kerosene. A deep pit in the drum shell should be filled with cement or one of the special preparations devised for just such purposes. While such measures help prevent further action within the drum the real remedy lies in preventing the entrance of entrained air with the feed water. There is no sense in endeavoring to prevent pitting by the method described, which is only palliative, at best, if no steps are taken to locate and remedy the cause of the trouble.

In outlining some of the economies which may be practiced in the care and upkeep of marine watertube boilers, we have purposely passed over details of overhaul and repair common to most boilers. No one appreciates more than the marine engineer the importance of having the power plant in first class condition, and his splendid record of achievement in break-down repairs at sea has been made principally by the happening of the unexpected and not from neglect or oversight on his part.

An Analysis of Claims of the Electric Drive Over the Geared Drive

(Continued from page 419)

As to the backing power, this feature has no practical value, as it bears only on the maximum speed of the vessel that can be eventually attained in the astern direction and not on the actual ability to stop and maneuver. Furthermore, too much power applied to a propeller, with the blades working on their backs, produces cavitation and nullifies the purpose intended.

In reply to the last point, it can be said that in all modern geared turbine installations there are generally fitted special impulse turbines of rugged design, and the argument against derangement of same is entirely fallacious, there being no record of a single case where trouble has been experienced of this nature when so fitted.

ELECTRIC DRIVE MORE EXPENSIVE AND HEAVIER

The electric drive is both more expensive and heavier, which varies with the class of vessel.

For a vessel of the scout cruiser type the weight is about 300 tons more, with the cost about 25 percent greater.

CONCLUSION

From the foregoing it is evident that the electric drive is far from fulfilling the promises of its advocates, and it is this which possibly explains their reluctance to publish anything other than theoretical figures pertaining to same.

Some comparisons have been made by the electrical advocates using the old direct drive steam installations for this purpose, but which have no particular bearing on the subject, on account of this earlier drive having for some time not been considered for new construction.

Influence of Speed on Economy of Motorships

Faster Ship is at a Disadvantage Because of Initial Cost of Larger Power Plant and Increased Consumption of Fuel

By L. B. Chapman*

IN fixing the characteristics of a new design, comparative studies are often made to determine the influence of the following factors on the operating expenses:

- 1. Type of machinery.
- 2. Size of ship.
- 3. Speed of ship.
- 4. Speed of handling cargo.
- 5. Length of voyage.
- 6. Percentage of full load capacity carried per trip.

A number of these items have been taken up by the writer in previous articles in MARINE ENGINEERING AND SHIPPING AGE. In this article it is proposed to investigate in a systematic manner the effect of various speeds on the operating expenses of a cargo ship of given dimensions.

The ship selected for this comparison has the following characteristics:

Length between perpendiculars	420 feet
Beam	57 feet
Molded depth	35 feet
Loaded draft	27 feet

The block coefficient has been decreased slightly with increased speed, giving a slightly finer ship for the higher speeds. Speeds of 9, 10, 11, 12 and 14 knots have been selected and the effective horsepower has been carefully calculated from model tank data. The propeller efficiencies have been taken from Taylor's $\rho\delta$ diagrams and the shaft horsepower has been increased 20 percent over that expected on trial to allow for increased power in service. All five ships are twin screw and the revolutions per minute have been made 115 for all the ships, which gives the 14-knot ship an advantage of about 10 percent in propeller efficiency over the 9-knot ship. If the revolutions per minute for the 9-knot were reduced to improve the propeller efficiency, the cost and weight of the machinery would increase, resulting in little if any overall gain.

The particulars of the five ships are tabulated in Table I. It will be observed that the gross deadweight decreases as the speed is increased, due to the heavier machinery weights in the faster ships. The net cargo deadweight also decreases, due to the decrease in the gross deadweight and to the increase in the fuel weight required with increased horsepower. The data and results of the operating expenses for a 5,000 mile voyage are given in Tables II and III. Line 17 in Table III shows that the freight rate to give a 10 percent return on the investment increases with speed and that the profit for a freight rate of \$7.03 per ton increases rapidly as the speed is decreased.

CAPITAL CHANGES DETERMINING FACTOR

The 9-knot ship has a net cargo deadweight capacity

*Head of course in Ship Construction and Marine Transportation, Lehigh University, Bethlehem, Pa.

It should be borne in mind that this comparison is for ships especially designed and powered for the speeds stated. It is not intended to indicate that a ship should be run at a speed less than that corresponding to its maximum power. If, for example, a speed of 10 knots can be obtained with a 9-knot ship without any increase in first cost or machinery weight, calculations of the operating expenses will quickly show that there is a distinct gain in favor of the 10-knot ship. As pointed out in the article, the high speed ship is handicapped not so much because of the increase in fuel costs as in reduced deadweight capacity and increased capital charges.

20.5 percent greater than that of the 14-knot ship, due to the saving in machinery and fuel weights; yet the 14-knot ship makes 3.7 more trips per year and carries 11,500 more tons (13½ percent) of cargo per year because of its greater speed. The 14-knot ship, however, loses out because of the greater capital charges (line 5, Table III), caused by the increased first cost of the larger power plant, and because of the increased fuel cost (line 6). The engine crew for the faster ship has been slightly increased by the addition of more oilers and a machinist-storekeeper. The port charges of the faster ship are also greater than those for the slower ship, due

to the greater number of turn-arounds effected per year. If the speed were reduced below 9 knots, in all probability an optimum speed would be found that would give a lower freight rate or a greater return on the investment than shown by the 9-knot ship. This comparison has not been carried below 9 knots, as it is felt that speeds lower than this and powers below 1,500 shaft horsepower are not to be recommended for a ship of this size.

The foregoing comparison clearly shows that there is no advantage in building a general cargo ship for speeds greater than 9 or 10 knots unless special inducements are offered in increased freight rates. When passengers, fruit, or refrigerated cargoes are carried, of course higher speeds are demanded and the earnings per ton of deadweight are greater.

The costs of the machinery, per shaft horsepower used in the above comparison have been assumed arbitrarily and may not agree with all types of Diesel machinery. They are, however, comparable and any reasonable change in the machinery costs will not affect the relative position of the ships in the table.

Table I.—Particulars of Ships

1. Sea speed in service.....	9	10	11	12	14
2. Block coefficient	.80	.79	.78	.76	.74
3. Displacement	14,500	14,300	14,100	13,800	13,400
4. Net tonnage	4,700	4,650	4,600	4,500	4,400
5. V/√L	.44	.49	.54	.59	.69
6. Model E. H. P.	740	1,000	1,290	1,620	2,600
7. Calculated S.H.P.+20% reserve	1,500	2,000	2,500	3,100	4,800
8. Hull weight	3,900	3,890	3,880	3,870	3,830
9. Machinery weight (lbs. per S.H.P.)	630	600	580	570	560
10. Machinery weight	420	535	650	790	1,200
11. Gross deadweight	10,180	9,875	9,570	9,140	8,370
12. Calculated fuel for 5,000 miles + 20%	205	250	280	320	425
13. Stores, provisions and water (tons)	50	50	50	50	50
14. Net cargo deadweight.....	9,925	9,575	9,240	8,770	7,895
15. Number of engine crew	12	15	15	15	16

Table II.—Data for a Voyage of 5,000 Miles

1. Speed in service..	9	10	11	12	14
2. Days on run + 5%	24.3	21.9	19.9	18.2	15.6
3. Fuel per S.H.P. per hour in service	.44	.44	.44	.44	.44

4. Fuel per hour at sea (lbs.)	660	880	1,100	1,365	2,110
5. Fuel per day (tons)	7.07	9.43	11.80	14.65	22.6
6. Rate of stevedoring (tons per hatch per hour)	30	30	30	30	30
7. Rate of stevedoring (tons per 10 hrs.)	1,500	1,500	1,500	1,500	1,500
8. Calculated time in port + 10%	14.55	14.10	13.55	12.85	11.60
9. Days per single trip	38.85	36.0	33.45	31.05	27.20
10. Single trips per year	8.63	9.30	10.0	10.80	12.30
11. Tons of cargo carried per year..	85,500	89,000	92,400	94,700	97,000
12. Cost of hull.....	\$720,000	\$720,000	\$720,000	\$720,000	\$720,000
13. Cost of machinery	\$280,000	\$350,000	\$420,000	\$510,000	\$750,000
14. Total cost of ship.	\$1,000,000	\$1,070,000	\$1,140,000	\$1,230,000	\$1,470,000

A summary of the data is given in Table IV. Line 5 shows the shaft horsepower installed per ton of cargo deadweight. It is seen that the cost of the ship increases with the increase in speed; yet the carrying capacity of the ship decreases. Line 7 in Table IV gives the annual operating expenses per ton of cargo carried per 1,000 miles traveled and shows the increase in expenses as the speed is increased.

In the foregoing comparison all the installations have been made twin screw, the cargo handling rate has been kept the same and all other factors kept constant where possible in order that speed should be the only variable. This does not work to the best advantage of the ships in each case but it does give a fairer comparison of speed than would be the case if other factors were varied.

In conclusion, the writer wishes to make clear that the comparison given above is based on assumed ships and theoretical conditions and the results are intended only for comparative purposes. They are not intended to apply to a particular isolated case.

Table III.—Annual Operating Expenses

1. Speed in service (knots)	9	10	11	12	14
2. Depreciation (5%).....	\$50,000	\$53,500	\$57,000	\$61,500	\$73,500
3. Insurance (5%).....	\$50,000	\$53,500	\$57,000	\$61,500	\$73,500
4. Repairs, maintenance, overhauling (4%).....	\$40,000	\$42,800	\$45,600	\$49,200	\$58,800
5. Total capital charges (14%)	\$140,000	\$149,800	\$159,600	\$172,200	\$205,800
6. Fuel used at sea at \$12.20 per ton.....	\$18,100	\$23,400	\$28,600	\$35,100	\$53,000
7. Fuel used in port at \$12.20 per ton.....	\$1,530	\$1,600	\$1,650	\$1,690	\$1,740
8. Lubricating oil at 75c. gallon	\$1,860	\$2,450	\$2,980	\$3,660	\$5,540
9. Wages of crew.....	\$36,000	\$38,340	\$38,340	\$38,340	\$39,540
10. Subsistence at 70c. per man per day.....	\$8,950	\$9,700	\$9,700	\$9,700	\$9,950
11. Tonnage dues and port charges	\$29,150	\$30,800	\$32,400	\$33,600	\$36,550
12. Brokerage and management at 50c. per ton..	\$42,750	\$44,500	\$46,200	\$47,350	\$48,500
13. Stevedoring at 70c. per ton	\$119,500	\$124,500	\$129,000	\$132,500	\$135,500
14. Annual operating costs..	\$398,000	\$425,000	\$449,000	\$465,000	\$536,000
15. 10% on investment...	\$100,000	\$107,000	\$114,000	\$123,000	\$147,000
16. Total	\$498,000	\$532,000	\$563,000	\$588,000	\$683,000
17. Rate per ton of cargo to give 10% return on investment	\$5.83	\$5.98	\$6.10	\$6.21	\$7.03
18. Profit for a rate of \$7.03 per ton.....	20.2%	18.7%	17.3%	16.2%	10%

Table IV.—Summary

1. Speed in service (knots)	9	10	11	12	14
2. Rate per ton to give 10% return	\$5.83	\$5.98	\$6.10	\$6.21	\$7.03
3. Profit for a rate of \$7.03 per ton	20.2%	18.7%	17.3%	16.2%	10.0%
4. Cost per ton gross D.W.	\$98.50	\$108.50	\$119.00	\$134.50	\$175.50
5. S.H.P. per ton of cargo D.W.	0.151	0.209	0.271	0.353	0.61
6. Cost of fuel used at sea per 1,000 cargo ton-miles	4.25	5.27	6.20	7.40	10.90
7. Annual operating cost per 1,000 cargo ton-miles..	\$0.93	\$0.96	\$0.975	\$0.982	\$1.105
8. Percentage of year at sea	57.5%	56.0%	54.5%	53.0%	52.6%

Distinctive Tendency Toward Self-Insurance Noted

Merchants Who Adopt Such a Course Run Grave Danger—Lack Facilities for Obtaining Prompt Knowledge of Disasters and Minimizing the Results

By "Bordereaux"

THERE is a slow but nevertheless steady growth in self-insurance among various classes of merchants in this country, and underwriters are regarding it with considerable concern. Within recent months there has been a noticeable movement in that direction on the part of large importers, especially chain department stores whose import business is chiefly confined to the movement of goods from Western Europe to the United States. Experiments in self-insurance are being made in the shipment of merchandise over the established transatlantic routes where voyages are relatively short and the best types of vessels are employed. It is an experiment of very doubtful advantage, for everyone familiar with the North Atlantic is aware of the uncertainty of the elements and of the nature of the severe and disastrous storms that frequently rage there.

In the long run, the law of average will certainly take its toll of the man who takes chances. There are innumerable accounts which have shown underwriters a profit, year in and year out, but where a sudden disaster has wiped out years of accumulated profit and left a debit balance. Other accounts seem fated to share in every possible bad fortune at sea; and these bring the insurer nothing but losses. The underwriter carries the good with the bad, because he operates

by the law of average. Should he have a disastrous year on the North Atlantic he can make up for it by better luck in other parts of the world, but the individual self-insurer has no such spread of risk, which is absolutely fundamental to a proper working out of this inexorable law. It is economically unsound for shipowners or merchants to risk their profits in an experiment where the cards are stacked against them; and particularly is this so in a branch of insurance such as marine, where the profits are notoriously small. Rates on imports of general cargo from Europe are lower at the present time than for years, which reflects the relative freedom from serious losses. The shipper has the benefit of these low rates; why, then, should he run the risk of incurring a severe loss which will wipe out his insurance reserve and leave him with a charge on the wrong side of the ledger? Again, the self-insurer is without the machinery necessary for obtaining prompt notice of disaster, which permits the underwriter to take steps to minimize the loss or preserve the venture. Furthermore, in cases of general average there are many complicated situations which arise, and unless the proper steps are taken loss and embarrassment may readily result to the shipowner or shipper, depending upon the circumstances involved in the case.

Hague Rules Endorsed

THE idea of a uniform ocean bill of lading has appealed strongly to the Chamber of Commerce of the United States. At its recent annual meeting, the Transportation Group adopted the following resolution, which was proposed by D. Roger Englar, who represented the Association of Marine Underwriters of the United States:

Whereas, The Chamber of Commerce of the United States at its tenth annual meeting, held in Washington, D. C., in 1922, put itself on record as indorsing The Hague Rules, 1921, as a step in advance and asked Congress to enact legislation for The Hague Rules with such interpretations as may be deemed necessary; and

Whereas, These rules have been further modified and are now before us in the form of the Brussels Draft International Convention for the Unification of Certain Rules Relating to Bills of Lading; therefore, be it

Resolved, That this chamber approves the said Brussels Draft International Convention as an improvement over The Hague Rules and asks Congress to enact legislation putting the said Draft International Convention into effect.

Restriction in English Clauses

ENGLISH underwriters announce important alterations in their hull contract. They have decided not to include hereafter the four-fourths "running down" clause, nor protection and indemnity risks in time policies, except in case of liners and other special service vessels in which such risks have regularly been included in the past. This agreement applies to all insurance placed on English conditions.

In Great Britain it is generally regarded that the granting of full collision cover and the writing of P. & I. risks has extended beyond the bounds of underwriting safety. It has always been accepted that one-fourth of the collision risk ought to be run by the owner. The latter joins with other owners in mutual associations, and shares with them the claims that arise from writing vessels in common. These associations play the leading role in the adjustment of collision liability claims. They also cover protection and indemnity risks in full. The English authorities insist that "in eliminating the one-fourth collision liability and the whole of P. & I. risks from the marine policy, underwriters are assuring the associations of a continuance of business and, at the same time, assuring themselves of the continuance of the excellent service which these associations undoubtedly render the market."

Carrier's Floating Policy

LIABILITY under a general floating marine policy taken out by a carrier covering goods to be shipped by the latter was gone into recently in a case before the New York Supreme Court, Appellate Division, 199 New York Supp., 46. The court held that under such conditions as arose in this case the shipper is entitled to sue the insurer for loss sustained under such a contract and need not be relegated to their claims as general creditors against the bankrupt carrier.

The suit was on appeal from the Supreme Court. It was brought by Nicholas P. Young and another, as co-partners, against the St. Paul Fire and Marine Insurance Company and another. The plaintiffs were engaged in the bagging business, and shipped 298 bales of gunny bags with the Inland Waterways Steamship Corporation which had a policy with the several insurance companies covering goods shipped by it "for account of whom it may concern." The goods were destroyed by fire due to lightning. The insurer re-

sisted payment on the ground that the carrier was the insured and the party through which all rights of shippers in the first instance should be enforced, and that the equitable rights of plaintiffs under the policy were limited to their proportion of such sums as might be recoverable by the carrier, or its receivers. The receivers of the carrier raised the contention that the policy was one of reinsurance, to re-insure the carrier for losses it might be obligated to adjust with the shipper, and for which it should be liable, and that therefore the plaintiffs had no interest in the proceeds of this insurance, and were not entitled to recover in this action, being only general creditors of the carrier. The court held that these contentions were without merit, and that the insurance on the bags was effected for the benefit of the plaintiffs.

Leviathan's Insurance

WHEN the world's largest vessel, the *Leviathan*, passed out of the Newport News yards, where she had been reconditioning for the past thirteen months, her insurance automatically expired. Thereafter she was without coverage, except as the risk of the Shipping Board boats are regularly taken care of by the Government. Her policy had been for \$2,500,000, written in Syndicate "C." It attached April 10, 1922. The expiration was given as of May 20, 1923, "or until the vessel sails from Newport News." The underwriters had but comparatively few claims to meet during the cover period, and the insurance operation, taken as a whole, was profitable to the insurers and eminently satisfactory to the vessel's owners.

Marine Fire Hazards

AT the recent annual meeting of the National Fire Protection Association, held at Chicago, the report of the Marine Fire Hazards Committee was accepted and adopted as submitted without a change. This was a well-earned tribute to the fine work done by Mr. S. D. McComb and his associate committeemen. The committee was continued, and will now proceed to devote its attention to problems respecting hazardous commodities, gas engines and gasoline boats. They made certain recommendations along these lines, which were tentatively adopted, but they will require to be gotten into permanent shape. Hazardous cargoes come under the jurisdiction of the Interstate Commerce Commission. The committee earnestly invites criticism and suggestions from steamship owners, to the end that the handling of these subjects may be as comprehensive and satisfactory to all concerned as is at all possible.

Improper Recording of Bill of Sale

IN the case of the *Jean L.*, 286 Federal Reporter, 727, the claimant had a bill of sale on the vessel, which was recorded in the office of a State court, that was offered in evidence at the time of the trial in an attempt to show a prior lien but the Court said a bill of sale on a vessel is not admissible as evidence of title where it was not recorded in the office of the collector of customs, in the home port of the vessel as required by Rev. St. Sec. 4192 and there was no evidence that the claimant had any knowledge of the existence of the bill of sale. The recording of the bill of sale in the office of the clerk of a State court does not give constructive notice to a subsequent lien claimant, since the provisions of the United States laws and not those of the State apply to transfers of vessels or interests in them and especially where there is no State law authorizing bills of sale of personal property to be recorded by that court.

Protective Coverings for Shipbuilding Purposes: Paints

By Horace Holden Thayer *

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

IN a consideration of paints as a protective covering for shipbuilding purposes we will find it advantageous to group them in several classes, such as

- Priming paints
- Bottom compositions
- Interior paints, general
- Exterior paints, general
- Paints for special services
- Varnish and shellac

Before taking up any one of the paint mixtures it will be well to present specifications of the materials which go to make up the vehicle, or liquid portion, of the paint. They are oil, which generally should be pure linseed oil, turpentine, volatile mineral spirits and a drier. Linseed oil is what is known as a drying oil, that is, an oil which when spread out in a thin film readily takes up oxygen from the air and changes to a tough and elastic substance. Specifications for these, as drawn up in 1918 by the War Service Committee of the Paint Industry for shipbuilding purposes, may be considered as representative of good practice. These specifications, together with the same specifications for varnish, are given below. Shellac is merely gum shellac dissolved in alcohol.

In addition to linseed oil, China wood or tung oil and soya bean oil are of value in some paints. The former has great cohesion and good water proofing properties, while the latter is particularly of value for its adhesive properties. The use of soya bean oil makes a slower drying paint.

RAW OR REFINED LINSEED OIL

It shall be absolutely pure, well settled oil of best quality. It shall be perfectly clear at a temperature of 60 degrees F. and shall not show a loss of over 0.2 percent when heated to 212 degrees F., or show any deposit of "foots" after being heated to this temperature. It shall conform to the following requirements:

	Maximum	Minimum
Specific gravity at 15.5 degrees/15.5 degrees C.....	0.936	0.932
Or specific gravity at 25 degrees/25 degrees C.....	0.931	0.927
Acid number	6.	
Saponification number	195.	189.
Unsaponifiable matter, percent.....	1.50	
Refractive index at 25 degrees C.....	1.4805	1.479
Iodine number (Hanus).....		170.

These specifications agree with standard specifications D77-21T of the American Society for Testing Materials except that the latter use only the specific gravity at 15.5 degrees C. and have 0.931 as the minimum, and call for a minimum refractive index of 1.478.

BOILED LINSEED OIL

It shall be absolutely pure, well-settled linseed oil boiled with oxides of manganese and lead. It shall conform to the following requirements:

	Maximum	Minimum
Specific gravity at 15.5 degrees/15.5 degrees C.....	0.945	0.937
Acid number	8.	
Saponification number	195.	189.
Unsaponifiable matter, percent.....	1.5	
Refractive index at 25 degrees C.....	1.484	1.479
Iodine number (Hanus).....		168.
Ash, percent	0.7	0.2
Manganese, percent		0.03
Lead, percent		0.1

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

These specifications agree with standard specifications D77-21T of the American Society for Testing Materials except that the latter use only the specific gravity at 15.5 degrees C. and have 0.936 as the minimum, call for a minimum refractive index of 1.478, and specify a maximum of 0.3 percent calcium.

TURPENTINE

This specification applies both to the turpentine that is distilled from pine oleoresins, and commonly known as gum turpentine or spirits turpentine, and to the turpentine commonly known as wood turpentine that is obtained from resinous wood, whether by extraction with volatile solvents, by steam, or by destructive distillation. The bidder should state whether gum spirits or wood turpentine is furnished.

The turpentine shall be clear and free from suspended matter and water. The color shall be water white. The specific gravity shall not be less than 0.860 or more than 0.875 at 15.5 degrees C. The refractive index shall be not less than 1.468 or more than 1.478 at 15.5 degrees C. The initial boiling point shall be not less than 150 degrees C. nor more than 160 degrees C. Ninety percent of the turpentine shall distill below 170 degrees C. The polymerization residue shall not exceed 2 percent and its refractive index at 15.5 degrees C. shall not be less than 1.500.

The American Society for Testing Materials standard specifications D13-21T are approximately the same as this, but in some particulars they make a distinction between the requirements for gum spirits and those for wood turpentine.

VOLATILE MINERAL SPIRITS

This shall be a hydrocarbon distillate, water white, neutral, clear and free from water. It shall have no darkening effect when mixed with basic carbonate-white lead.

When 100 cubic centimeters are submitted to continuous distillation in an Engler flask with a condenser 22 inches long at an angle of 30 degrees with the horizontal, and cooled with water, the first drop shall issue from the condenser at a temperature of not less than 265 degrees F. and 97 percent shall distill below 470 degrees F.

When 100 cubic centimeters of the distillates are placed in a glass crystallizing dish 2½ inches in diameter in a steam bath maintained at a temperature of 212 degrees F., and evaporated, not more than 2/10 of 1 percent of residue shall remain after 2½ hours. The flash point shall be not less than 85 degrees F. when determined by the closed Abel tester method, the test being made in the usual official manner.

DRIER

It shall be composed of lead, manganese, or cobalt salts, or a mixture of any of these elements, combined with pure linseed oil and thinner. The thinner shall consist of approximately 75 percent volatile mineral spirits and 25 percent turpentine. It shall be free from adulterants, sediment and suspended matter. Resins or "gums" other than resin may be used at the option of the manufacturer (but the presence of resin in any form shall be cause for rejection). The drier shall not flash below 35 degrees C. (95 degrees F.) in an open tester. When the drier is thoroughly mixed with linseed oil that will not break under 315 degrees C. (600 degrees F.) in the proportion of 5 volumes of drier to 95 volumes of oil, no curdling shall result within 2 hours after mixing, and the mixture when flowed on a clean glass plate held in a vertical position, shall dry in not more than 18 hours at a temperature between 15 degrees and 35 degrees C.

VARNISH

The material shall be the best long oil varnish. It must be resistant to air, light and water. The manufacturer is given wide latitude in the selection of raw materials and processes of manufac-

ture, so that he may produce a varnish of the highest quality. Preference will be given to the rapid drying varnishes.

The varnish shall be clear and transparent.

The color of the varnish shall be no darker than that of a standard color solution, made by dissolving six grams of pure powdered potassium bichromate in 100 cubic centimeters of pure concentrated sulphuric acid (Specific gravity 1.84). Gentle heat may be used if necessary to perfect the solution of the bichromate. The standard color solution and a sample of varnish shall be placed in clear thin-walled glass tubes of the same diameter. The color comparison shall be made by placing the tubes close together and looking through them. The tubes used for this test shall be $\frac{5}{8}$ to $\frac{13}{16}$ inch in diameter, and shall be filled with the liquids to a depth of at least one inch.

When tested in an open tester, the varnish shall not flash below 95 degrees F. (35 degrees C.).

The film test shall be made on a film of varnish flowed on one side of a panel of bright tin which is 0.0125 to 0.0158 inch thick and about four inches wide by six inches long. The panel shall be thoroughly cleaned with benzol before applying the varnish. When the panel is placed in a vertical position and maintained at a temperature of 70 to 90 degrees F. (21 to 32 deg. C.), the varnish must set to touch at points within one inch of the side and top edges of the film, in not more than five hours and must dry hard in not more than twenty-four hours, to a clear hard glossy film.

The panel shall then be allowed to dry for a further period of not less than five days, and then brought to a temperature of from 70 to 75 degrees F. The panel with the varnished side on the outside, shall then be rapidly bent double over a rod $\frac{3}{8}$ inch in diameter. The varnish film must neither crack nor flake at the point of bending.

A basswood panel shall be filled with a coat of drop black in oil, thinned with turpentine and drier, and allowed to dry for at least ten days. The filler must have suitable body to give proper brushing, flowing and covering properties. A coat of varnish shall then be applied, allowed to dry for forty-eight hours and lightly sandpapered. A second coat of varnish shall then be applied and allowed to dry for seventy-two hours. The panel shall then be inclined at an angle of forty-five degrees, and a gentle stream of cold tap water allowed to flow for eighteen hours down the middle of the panel. After wiping off, with a chamois skin, any deposits due to tap water the varnish must show no appreciable whitening, dulling or other defects. A small stream of boiling distilled water will then be allowed to flow down another portion of the panel for twenty minutes. The water will be siphoned through a small glass tube directly from a container in which it is boiling, onto the surface of the panel, in such a manner that there will be no appreciable lowering of the temperature of the water before it touches the varnish film. The siphon delivery tube will be in a plane nearly parallel to the plane of the panel, so that the impact of the water will not tend to break the film. The varnish shall show no appreciable whitening and no more than a very slight dulling, or other indications of marked deterioration, either when observed immediately after removing from the water, or after drying for two hours.

The varnish shall be applied, in three coats, to two unfilled panels of maplewood. The panels must not be less than $5\frac{1}{2}$ inches wide by 18 inches long by $\frac{3}{4}$ inch thick. The first coat of varnish, after drying indoors for three days, shall be lightly sandpapered with No. 00 sandpaper before the application of the second coat. The second and third coats of varnish shall each be allowed to dry three days indoors, but neither coat shall be sandpapered or rubbed. A protective coat of varnish (not for test purposes) shall be applied to the back and edges of the panels. The duplicate panels shall then be placed outdoors at an angle of 45 degrees to the vertical and facing the south.

The durability of the varnish on the test panel must be equivalent to that of an approved varnish exposed under the same conditions.

The American Society for Testing Materials has standard specifications for a number of the more important paint pigments, which are of value as quality standards. They also have standard specifications for tung oil.

PRIMING PAINTS

The first coat of paint applied to the bare steel, wood or other material is the priming coat, and it naturally first demands our attention. A good priming paint is very important.

PROTECTION OF STEEL

Steel and iron are painted to protect them from corrosion which results from exposure to moisture and is accelerated by the presence of salt and other elements or conditions which induce galvanic action. A priming paint for steel work

should therefore be as impermeable as possible, should contain nothing soluble in water or that would attack the steel, should be a non-conductor of electricity and should contain nothing that would act with the steel to set up galvanic action. If it is of a nature to neutralize attacking acids in the air or water, so much the better. In addition to these qualifications the paint should adhere tenaciously to the surface and should form a good and hard foundation for subsequent coats. A soft film as a priming coat will result in the cracking and alligating of the subsequent coats.

The steel should be scraped or wire brushed clean of mill scale and dirt and made thoroughly free of oil, and it should be thoroughly dry. Lubricating oil or palm oil is sometimes rubbed over the surface to prevent corrosion during shipment and this will prevent the adherence of any paint. One of the best removers of such oil is benzene.

The oil used in priming paints for steel work should be pure linseed oil, preferably entirely raw. No mineral oil or non-drying oil of any kind should be used in it, as they prevent the paint's becoming sufficiently hard to give a good foundation for subsequent coats. Linseed oil when used as a coating without pigment makes a film that is too soft, as well as being somewhat porous and permeable, but when used with a pigment the film will dry hard. Boiled linseed oil produces a paint film which is harder and resists the softening action of water better than raw linseed oil, and this renders the former more desirable for outer coats, particularly where the coating is constantly in contact with water.

RED LEAD

Red lead is made by melting lead metal in furnaces and oxidizing it to litharge (PbO), a buff colored oxide. This when pulverized and again heated to the proper temperature takes on more oxygen and changes to red lead (Pb_3O_4), though there will usually be a small percentage of litharge unconverted. Too high a heat will result in a transformation of the red lead back to litharge again. The difficulty of producing a red lead entirely free from litharge may be readily imagined. Litharge is easily decomposed and enters into other chemical combinations, and it also, when in any considerable amount, acts on the oil causing the paint to become rosy and resulting in the objectionable caking of the pigment when the paint is allowed to stand. An excessive amount of litharge in red lead indicates that the pigment has not been ground finely enough and thus the presence of coarse particles which interfere with obtaining a good uniform paint film. Red lead produced by the oxidation of white lead is often called orange mineral, and a more complete oxidation and a resultant low percentage of litharge is more easily obtained by this process, but it is not always so obtained. One paint manufacturer states the composition of their orange mineral as 95.71 Pb_3O_4 and 4.29 percent PbO .

No priming paint thus far evolved has been proved by actual experience to equal a paint composed of pure red lead and pure linseed oil in the marine field. There is no other paint that makes such a hard, tenacious film. It is a good protection against electricity and acids. It stands high as regards impermeability, having a good thick film with a maximum of pigment. Red lead and pure linseed oil paint contains nothing soluble in water, and it dries rapidly through and through. The bright orange red color is also of value on a steel surface as showing up defects in the application of the coating.

An objectionable feature in the use of pure red lead paint is the fact that with the use of the red lead powder generally obtainable, the pigment soon settles to the bottom and cakes in a manner which prevents its proper mixing up again. The reason for this has been mentioned. This fact has in the past required that the paint be mixed fresh for the particular work in hand. In order to simplify this process one man-

ufacturer has for some years produced a red lead ground in linseed oil and sold in paste form, and quite recently they have gone a step farther and produced a liquid red lead paint. This has been made possible by the use of finely ground and highly oxidized red lead containing not less than 97 percent of Pb_3O_4 . The use of the pigment in paste form or the use of the liquid red lead paint obviates another objectionable feature, which is the danger of poisoning from the red lead powder when proper precautions are not taken by the user.

Paint specifications adopted in 1917 by the United States Shipping Board Emergency Fleet Corporation were prepared by Dr. P. H. Walker of the United States Bureau of Standards in collaboration with Dr. H. A. Gardner of the Institute of Industrial Research, Washington, D. C. For red lead paint they are as follows:

HAND MIXED RED LEAD PAINT

This paint shall be mixed not more than 48 hours before application. The pigment shall be pure oxides of lead containing not less than 85 percent Pb_3O_4 , the balance to be PbO . The paint shall weigh not less than 25 pounds to the gallon. The vehicle shall consist of pure raw linseed oil, liquid drier and volatile thinner (turpentine or mineral spirits, or a mixture thereof). It shall be free from resin. When applied to a smooth vertical iron surface, the paint must dry free from tack in twelve hours without running, streaking or sagging. Such a paint may be made on the following formula:

Red lead	20 pounds
Raw linseed oil	5 pints
Petroleum spirits	2 gills
Liquid drier	2 gills

The formula is the United States Navy formula for red lead priming paint although they require that the pigment shall contain not less than 94 percent of true red lead, Pb_3O_4 . When the paint is made up with red lead paste the Navy Department requires that it shall contain not less than 97 percent of Pb_3O_4 , so that it will not harden in the container. The paint weighs 25 pounds 4 ounces per gallon. It will be noted that the proportions are 32 pounds of red lead to 1 gallon of oil.

Thirty-three pounds or more of red lead to 1 gallon of oil can be used with profit. With about one-third of the oil boiled no drier is necessary, and the formula can consist of red lead and linseed oil alone. The more red lead to a gallon, the harder will be the paint, and the better for underwater service.

Dr. A. H. Sabin, an authority on red lead paints, in his book "Red-Lead and How to Use It," recommends the following for the painting of the *outside* of the hull: As soon as the shell plates are in place, a coat of red lead paint made with boiled linseed oil containing 40 pounds of pigment to the gallon of oil. A similar second coat below the water, with a second coat above the waterline having 36 to 37 pounds of pigment to the gallon of oil. Then a third coat having 33 pounds of pigment to a gallon of boiled oil below the waterline, and the same amount of pigment with the oil half raw and half boiled, above the waterline. He recommends as long a time as possible between coats, even up to a year if the vessel is to be three years on the ways after being plated.

The paste red lead before referred to can be mixed up with linseed oil to produce any desired weight of paint. The proportions for the equivalent of 33 pounds of dry red lead to the gallon of oil are 24.29 pounds of the paste to 0.48 gallon oil and the resulting weight per gallon is 28 pounds.

The formula for the ready mixed liquid red lead paint before mentioned in its natural orange-red color is—

Red lead	79.69 percent by weight
Linseed oil	19.31 percent by weight
Liquid drier	1.00 percent by weight

100.00 percent

The paint weighs 28 pounds per gallon, being heavier than the United States Navy standard paint, and one gallon contains about 22.3 pounds of red lead and 5.4 pounds of linseed oil. Taking the minimum specific gravity for linseed oil before mentioned at 0.932 we would have only 0.696 gallon of oil. This shows a proportion of about 32 pounds of red lead per gallon of oil, or the equal of the hard mixed paint before mentioned.

LEAD CHROMATE

The value of lead chromate as a pigment for priming paints on steel subjected to salt air is evidenced by tests made by the American Society for Testing Materials which will be more fully referred to later on. The paint of this nature made up by them stood at the top of the list. One of the paint manufacturers is marketing a paint of this type which is giving a good account of itself on ships, coal piers and other work about the water, and it has been passed upon by Dr. H. A. Gardner as promising excellent service on iron and steel structures. The formula for this paint is—

Pigment 45 percent	Lead chromate	25 percent
	Iron oxide (91 percent iron) ..	25 percent
	Silica	50 percent
Vehicle 55 percent	Linseed oil (heat treated)	64 percent
	Varnish, long oil, hard gum....	20 percent
	Drier (oil)	10 percent
	Thinner (turpentine)	6 percent

BLUE LEAD

At least one manufacturer of priming paints is marketing a product called sublimed blue lead in oil. The pigment, which is produced by subliming lead ore and collecting the fumes, is a slate gray powder and it is about half lead sulphate. It is said to remain perfectly suspended in the vehicle and at the same time to be free from hardening in the container.

This paint is another of those in the before mentioned tests of the American Society for Testing Materials and was awarded a rating second to that of the lead chromate paint. The composition of the pigment as used in the tests was approximately:

Lead sulphate	50 percent
Lead oxide	35 percent
Lead sulphide	5 percent
Lead sulphite	5 percent
Zinc oxide	2 percent
Carbon	3 percent

The writer does not know of any instances of its actual shipboard service, but it looks promising.

Applications of Arc Welding to Ship Construction

(Continued from page 424)

a paper read by Mr. Wall, before the British Institution of Mechanical Engineers in 1922: "This ship has been in commission for about 18 months. The welding employed in her construction has proved highly satisfactory. She has carried several cargoes of steel plating and similar material and has encountered heavy seas without showing signs of failure in any welded joint. At one time, in a collision, she received an indentation in her side without starting any welding. Lloyd's Register of Shipping recently examined this ship and reported that there were no signs of weakness, even at the break of the quarter deck, which usually happens with riveted vessels of this class."

Current Admiralty Decisions of Special Interest

By Calvert B. Gill*

Liability for Damage to Cargo

THE plaintiff in the case of the *Lake Fontanet*, American Maritime Cases Vol. 1, page 500, filed a libel to recover for damages to the cargo. The libel charges that the coffee was damaged by sweat and water by reason of it not being stowed with proper dunnage and by reason of the master and crew not taking proper precaution in the custody and care of the cargo. The defence offered was a provision of the bill of lading relating to sweating and that the dunnage was done in the manner usual and customary in the coffee trade, but the Court said although the damage resulted to the cargo from an excepted cause, yet if it could have been avoided by the exercise of proper skill and vigilance, the carrier was liable. That it is negligent to stow coffee with usual battens and matting for a voyage from a warmer to a colder climate, when sweating of the ship's hold could have been anticipated and other and safer methods of stowage could have been used.

Award for Services Little Above Towage

IN attempting to secure a large reward for salvage by towing a schooner a distance less than one hundred miles the Court in *The Lewis Brothers*, 287 Federal Reporter, 143, said that where the services for which salvage was claimed consisted of towing a schooner for ninety-five miles, which occupied about thirteen hours and delayed the steamer doing the towing only about ten hours, without requiring any substantial deviation from her course, so that the service amounted to but little more than ordinary towage, an award of \$500 as salvage is sufficient and since only ordinary work was required of the crew of the towing vessel, the entire award should go to the owners of the vessel.

Conditional Sale Contract Does Not Authorize Liens

A CONDITIONAL contract for the sale of a vessel did not, by a provision that the buyer should discharge any liens against the vessel within 15 days, grant the buyer power to impose liens on the vessel where that was contrary to the intention of the parties, as manifested by a requirement that the buyer should carry a certified copy of the agreement and take such other appropriate steps as would give notice that he has no authority to suffer a lien to be imposed on the vessel, but was inserted in recognition of the fact that under certain circumstances those dealing with the ship would have a lien, despite the terms of the contract. *The Henry S. Grove*, 287 Federal Reporter, 247.

Jurisdiction of Action for Injuries on Dock

THE plaintiff, who was employed as a mess boy to serve meals to the seamen and do any work required in the steward's department of the ship, was ordered by the first mate, over the plaintiff's objection, upon the wharf

to assist in the unloading of the ship and while so employed was injured by the negligently dropping of a loaded cargo sling upon him, endeavored to recover damages from the owners of the ship under the Merchant Marine Act of 1920, section 33, but the Court in *Hughes vs. Alaska Steamship Company*, 287 Federal Reporter, 427, said that the court has no jurisdiction of a suit instituted under the Merchant Marine Act of 1920, section 33, providing that any seaman who shall suffer personal injury in the course of his employment may at his election maintain an action for damages at law; no intention being shown by section 33 to include in the new remedy any cases in so far as territorial jurisdiction is concerned, not covered by the Act of March 4, 1915, section 20.

Ship Liable for Negligent Care of Seaman

IN the case of *Unica vs. United States*, 287 Federal Reporter, 177, the libelant seeks to recover damages, not because of the injury sustained when he accidentally fell into the hold of the vessel, but because of the negligence of the master in not getting him into a hospital sooner, so he could receive proper surgical attention. The Court said that the ship owes the seaman the duty of maintenance and care when he is seriously injured and if there is no surgeon on the vessel, it is the duty of the master to have him taken to a hospital at a port which would have resulted in but slight deviation from the vessel's course or, if the seaman waived his right to be taken to that hospital, the master was negligent in failing to have him removed to a hospital at the ship's destination for six days after the arrival of the ship in that port. Where such negligence exists the ship's owner is liable in damages.

Charterer Liable for Demurrage

WHERE a charter party required the vessel to be delivered at designated port between specified days, charterer to deliver cargo alongside and to load and discharge in five weather working days, or failing to do so to pay demurrage, lay days to commence from the time the captain reports ready to receive cargo and loading was delayed because of limited port facilities requiring vessel to wait its turn, the charterer was liable for demurrage, as it knew or should have known of the conditions and custom of loading at such port and contracted with reference thereto. The Court further states, that under charter parties requiring the charterer to pay demurrage after the expiration of the loading time agreed on and fixing lay days as commencing from the time the captain reports himself ready to receive or discharge cargo, the commencement of the lay days is at the expiration of such period after the service of notice of arrival by the master as the ship would require in the exercise of due diligence to haul to her wharf or pier, if the same were then provided. *The Lake Yelverton*, 288 Federal Reporter, 92.

A NEW DRYDOCK, 160 feet long, 44 feet beam, to accommodate vessels up to 175 feet long and weighing 5,000 tons, was opened on June 25 by the Riley Drydock Company, foot of Mechanic Street, Buffalo, N. Y.

* Attorney at Law, Baltimore, Md.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Formula for Bow Wave Length and Contour

Q. (1,201).—Can you give me a formula for the determination of the bow wave length and contour for a moving boat or ship?

A. (1,201).—Admiral Taylor, in "Speed and Power of Ships," Volume I, pages 73 to 76, discusses Wave Resistance generally. On page 74 he states that, if V is the speed of the ship in knots, the length of the bow wave from crest to crest is $0.5573 V^2$.

On pages 108 to 111 he discusses squat and change of trim. The following is quoted from pages 110 and 111:

"Squatting is often thought to be a cause of excessive resistance. As a matter of fact, it is simply a result of large bow wave resistance. At $\frac{V}{\sqrt{L}} = 1.1$ to 1.2 the first hollow of the bow wave

is somewhere near amidships and the second crest somewhere forward of the stern holding it up, as it were. With increase of speed the crest moves aft clear of the stern and the hollow moves aft toward the stern. The stern, of course, drops into this bow wave hollow, causing the squatting or rapid change of trim noticed. As speed is increased the hollow in turn moves beyond the stern and the vessel advances on the back of its own bow wave, as it were. The higher the speed, the longer the bow wave, and the closer the vessel is to the crest.

"It is perfectly true that marked squatting generally means great resistance, because it is the result of an excessive bow wave with a first deep hollow. With no bow wave there would be no squatting, and with slender models having small bow waves squatting is much less marked than for short full models. In every case, however, it is a symptom rather than a cause of resistance."

With very short boats driven at very high speeds the second crest is far aft of the stern, so that the boat itself is on the back of its own bow wave, but very close to its crest.

It is probably impracticable to derive the wave contour of a given boat theoretically. Perhaps a reasonable approximation to it might be made by developing a trochoidal wave of the length given by the above formula and a reasonable proportion of height to length.

It is noticeable in tests that while for a given model the ratio, length to height of bow wave, seems fairly constant with varying speeds, this ratio varies widely from model to model depending upon the type of the forebody. Hence, the selection of the proper value for this ratio would depend upon observation of either models or boats of the type contemplated.

Clearances for Pins and Journals

Q. (1,202).—Could you give me some rule by which I could determine the amount of clearance to allow on bearings and pins on different types and sizes of marine engines? I noticed a rule given by Dyson in his handbook, but this does not seem to hold good; also, could you recommend a book on this subject that would be suitable for merchant ship engineers? J. W. A.

A. (1,202).—The best information on this subject with which the writer is acquainted is tabulated below and is taken

from the section on "Reciprocating Engines" prepared for Sterling's Marine Engineers' Hand Book by Wayne T. Dimm, B.S., assistant chief engineer, Newport News Shipbuilding and Dry Dock Company.

Satisfactory Clearances for Pins and Journals

Clearances in Inches for Pins		Diameter in Inches	Clearances in Inches for Journals	
Max.	Min.		Max.	Min.
0.005	0.002	5	0.005	0.0025
0.008	0.004	10	0.010	0.005
0.012	0.006	15	0.015	0.0075
0.015	0.008	20	0.020	0.010
0.018	0.010	25	0.025	0.0125

Bearing Clearances in Inches for Large Engines in Good Alinement

Crosshead pin brasses.....	0.006 to 0.007
Crank pin brasses.....	0.008 to 0.009
Main bearings.....	0.009 to 0.010
Eccentric straps.....	0.010 to 0.015
Crosshead slippers.....	0.010 to 0.012
Thrust shoes.....	0.005 to 0.007

Permissible Clearances on Lignum-Vitæ Bearings

Diameter of Journal in Inches	Minimum Clearance in Inches for New Bearings	Wear in Inches at Which Bearings Should Be Removed
8.....	0.050	$\frac{1}{4}$
10.....	0.060	$\frac{1}{4}$
12.....	0.075	$\frac{1}{4}$
16.....	0.100	$\frac{3}{8}$
20.....	0.125	$\frac{3}{8}$

Lignum vitæ must be well water soaked before being bored out.

Efficiency of Surface Propellers

Q. (1,203).—How does propulsion by surface propellers, as exemplified by the Hickman drive, compare in efficiency with that of the ordinary submerged propeller?

A. (1,203).—This is a large subject and one which has not yet been thoroughly investigated. The surface propeller and the vane propeller, now being developed in England, are both propellers which are designed to operate at partial submergence. The hub of the surface propeller is just above the surface of the water when the vessel is under way. Only the blade tips of the vane propeller act on the water. It results that the resistance of the shafting and struts or bossing is eliminated when either the surface or the vane propeller is used. This resistance amounts to from 5 to 10 percent of the bare hull resistance of twin screw vessels of moderate speed length ratio. In faster vessels it may be still greater.

Certain experimental basin tests indicate that a propeller, when not behind a hull, is more efficient when working as a submerged than when working as a surface propeller. This superiority is of the order of 6 to 8 percent.

The experience gained with a small vessel equipped with vane propellers shows a gain in propulsive efficiency of from 20 to 30 percent as compared with the same vessel fitted with submerged propellers.

Both the vane and surface propellers involve large diameters and low revolutions as compared with the submerged propeller designed for the same power. The result is slow turning machinery or the introduction of gearing. In either case, increases of weight and space are involved.

Accordingly, it would appear that both surface and vane

propellers merit the careful consideration of the designer. The exact value relative to that of the submerged propeller and the services or types of vessel to which they are particularly adapted are yet to be accurately determined.

Use Area of Largest Section in Calculating Prismatic Coefficient

Q. (1,204).—In calculating the value of the prismatic coefficient for a vessel whose largest sectional area is not at her half length should the area of the largest section or that of the section at the half length be used?

A. (1,204).—The area of the largest section is always to be used regardless of its fore and aft location. For purposes of design the value of the prismatic coefficient lies in the conception which it conveys to the designer of the longitudinal distribution of the vessel's displacement. The most important features of this distribution are the fore and aft location and value of the area of the greatest section. Upon these two features largely depend the shapes of the curves of sectional areas both of the fore and after body. This knowledge is of great importance in powering ships. The area of the section at mid length has little bearing upon resistance or power except (as is generally the case) when it is the section of greatest area.

PERSONAL MENTION

FRANK I. THOMPSON, commissioner of the United States Shipping Board, has been reappointed as a Shipping Board commissioner for a six-year term.

J. J. DWYER, special assistant to the passenger traffic manager of the United States Lines, has been appointed manager of the third class department of the company.

MORRIS MALKIN has resigned as head of the chartering department of the United States Shipping Board to rejoin the staff of Daniel Bacon, agent of Elder Dempster and Company, Ltd.

BERT E. HANEY, a lawyer of Oregon active in democratic politics, has been appointed a member of the United States Shipping Board, succeeding former Senator George E. Chamberlain. Mr. Haney is a member of the law firm of Joseph, Haney and Littlefield, which specializes in the practice of business and commercial law.

HARRY E. DEVOY has been appointed manager of the New York office of the J. H. W. Steele Steamship Lines succeeding B. M. Flippin who has retired after serving for the past four years as vice-president, traffic manager and head of the New York office of the company. Mr. Devoy was formerly Mr. Flippin's assistant.

WILLIAM LAMBIE, a Scotch naval architect and yacht designer, has established headquarters at Los Angeles harbor, Cal., where he is designing pleasure yachts and service power boats. During the World War Mr. Lambie was naval architect for the Southwestern Shipbuilding Company at Los Angeles and had charge of the construction of twenty-five steamers built at the plant for the Emergency Fleet Corporation and private interests.

CAPTAIN A. T. HUNTER, for the past three years operating manager of the General Steamship Corporation, San Francisco, has been appointed marine superintendent of the United States Lines with headquarters in New York. Prior to joining the General Steamship Corporation Captain Hunter was with the Pacific Mail Steamship Company. At the outbreak of the World War he joined the troopship *Northern Pacific* as commander and, under his direction, the vessel made a record in transporting troops across the Atlantic.

CAPTAIN H. H. BIRKHOLM, formerly northwest manager of the General Steamship Corporation, has been appointed operating manager of the corporation succeeding Captain A. T. Hunter.

DANCHERT SMITH, of Arnesen, Christensen and Smith, naval architects and consulting engineers, Christiania, Newcastle-on-Tyne and Cardiff, a firm which has a large clientele among Scandinavian

Danchert Smith

shipowners, has recently been created a Doctor of Science with highest honors, at the Technical University of Danzig. This degree was awarded on Dr. Smith's important paper, "Ueber die Drehfestigkeit der Schiffe (Torsional Strength of Ships)," based on scientific researches which have, after exhaustive laboratory tests of steel ship models built for the purpose, resulted in establishing a complete theory for calculations of vessels' strengths, relating to torsional stresses, which no doubt will be of great universal interest and assistance to shipbuilders and naval architects, and beneficial to shipowners.

REAR ADMIRAL LOUIS R. DE STEIGUER became commandant of the Boston Navy Yard on June 14, succeeding Rear Admiral Henry A. Wiley, assigned to command a division of the battle fleet of the navy with the rank of vice admiral.

CAPTAIN HERBERT HARTLEY, commander of the *Leviathan*, was born in Oswego Falls, N. Y., 1875, and began his seafaring career as a cadet on the frigate *Saratoga*, loaned by

Captain Herbert Hartley

the United States Navy to the State of Pennsylvania as a training ship. During his two years' service aboard the *Saratoga*, Cadet Hartley was instructed in seamanship by two young officers then rating as ensigns, but who since have won international fame as naval officers. These two men were Admiral William S. Sims and Captain William H. Fletcher. In 1895 Commander Hartley entered the service of the American Line as a cadet and continued steadfastly with that line until his recent appointment as commander of the *Leviathan*. The greater part of Captain Hartley's career was spent on board the *S. S. St. Louis*. During the World War this vessel, renamed the *Louisville*, was active in transport service and was the first armed American merchant ship to cross the German submarine zone. During the war Captain Hartley earned for himself many honors, including the Navy Cross for his exceptional devotion to duty and bravery. After the war Captain Hartley commanded various vessels flying the American flag until he received the appointment as commander of the *Leviathan*.

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

Specifications Out for Clyde Ships

BIDS on approximately \$4,000,000 worth of work, involving the construction of two new passenger and freight ships for the Clyde Line are expected to be opened early in July, according to latest reports. Plans and specifications for the construction of two large vessels and providing for an alternate proposition covering two smaller vessels have been issued by Theodore E. Ferris, naval architect, and a decision on this contract is looked for next month.

It is understood that the larger type vessel will have a length of about 410 feet between perpendiculars, 55 feet beam, 32 feet 9 inches depth to hurricane deck with a load draft of about 18 feet. The ships will be driven by turbine engines, steam being supplied by 4 Scotch boilers burning oil for fuel. They will probably be required to develop a speed of 15 knots.

Navy to Seek 15 New Vessels From Incoming Congress

IT has been learned that at the coming session of Congress the Navy Department will present a building program of eight cruisers, four river gunboats and three cruiser submarines, to the Budget Bureau and Congress.

The General Board has been instructed to consider plans which will give the navy the most efficient vessel of the cruiser type within the limitation of the Four Power Naval Treaty, since that treaty limits cruiser tonnage to 10,000, according to Secretary Denby. The eight new ships will probably follow closely the design of the Detroit class, now in progress of delivery.

The four gunboats will be for the Chinese river patrol as a recent inspection of the old vessels now engaged in that patrol indicated that they must be replaced as quickly as possible. In this connection, Secretary Denby said: "In view of the situation in China and the vast amount of trade at stake, the department feels it is most imperative that small modern gunboats be immediately authorized by Congress."

Tug and Lighter Planned

THE Southern Pacific Company, Pier 49, North River, is planning the construction of a steel harbor tug and a wood or steel harbor steam lighter. The tug will have a length of about 95 feet and it will be equipped with a compound condensing oil

American Marine Congress Called for November 5-10 to Be Greatest United Move for Merchant Marine

THE Board of Directors of the American Marine Association has authorized the calling and holding of an American Marine Congress, during Marine Week, November 5-10, 1923, in New York City. It will be called by the American Marine Association in collaboration with the United States Department of Commerce, and other government departments and a great number of marine and allied organizations, including manufacturers, commercial, export, trade, transportation, farm, and labor groups.

POLICIES

The policy of this Congress will be one of self-defense for American shipping, and will function along the following lines:

(1) To urge, sponsor and recommend the modification or repeal of statutory restrictions or laws which tend to burden the world-wide competing capacity of American ships, but at the same time to maintaining or establishing all necessary restrictions as pertain to the safety of passengers and crews, protection of goods, and protection of rights, quarters and living standards of American crews.

burning engine, while the lighter will be about 112 feet in length and also equipped with an oil burning engine. Plans and specifications are expected to be issued to bidders in about a week or ten days.

Western Farmers and Manufacturers Conferred June 28-29

INVITATIONS were accepted by the American Steamship Owners Association, the Shipping Board, the Council of American Shipbuilders, the United States Ship Operators Association, the National Merchant Marine Association, and the Foreign Trade Council to attend a meeting of the Middle West Farmers-Manufacturers Conference held in Gibson Hotel, Cincinnati, June 28 and 29. This gathering, which is a very encouraging sign because of an awakening interest in marine affairs by farmers and others in the interior, had for its purpose the discussion of a means for stimulating foreign trade by the use of American flag ships.

The conference believes in the establishment of a powerful national merchant marine without subsidy, and representatives of the various shipping groups, as well as Senators from twenty middle Western states and twelve Atlantic and Gulf coast states had been asked to be prepared with suggestions for a plan looking to this end which can be formulated into a bill for presentation to Congress.

(2) To recommend the adoption of such new legislation as will increase the world wide competitive capacity of American ships.

(3) To recommend and urge such necessary modifications and changes in the steamship code as may be advantageous.

(4) To develop and recommend such aid as will permit of an advantage in favor of building and repairing in American shipyards, with American labor, and materials.

(5) To recommend such standardization of construction and operation as will tend to reduce operating costs and increase competitive capacity.

(6) To recommend and urge the repeal of such legislation as permits of government agencies (such as navy yards) competing with private enterprises (such as private ship yards).

(7) To consider and make recommendations concerning government owned ships or lines competing with private ownership.

(8) To consider the advantages of reciprocal agreements with foreign lines on both outgoing and incoming shipments.

The Honorable Herbert Hoover, Secretary of Commerce, expressed the belief that this was the best effort he had yet heard of in the marine field, and that he would assist and co-operate to the utmost, and that the entire services of his department were at the association's disposal.

ORGANIZATION

The organization of the American Marine Congress will be as follows:

Administrative Committee

The working organization, in which is vested the authority to negotiate, arrange, direct and execute all plans, or in other words the machinery of the Congress:

Walter M. McFarland, Chairman;
Frank J. Shipman, Vice Chairman; K. Warren Heinrich, Secretary; Charles F. Scott, James Plummer, Edward A. Colson, Frank W. Sterling, Fred B. Webster. All representing American Marine Association.

All communications should be addressed to the Secretary, who will route them to the proper party for action.

Central Committee

This committee will determine policies subject discussions, sectional meetings, speakers, papers, etc., and is to work in close co-operation with the Administrative Committee. The President of the American Marine Association to always be Chairman of this Committee.

The personnel of this Committee is not yet complete, but present plans contemplate

Outboard Profile of Passenger Steamers Proposed for California-Australia Service

that the President, or an officer of each of the following organizations will comprise the Committee: American Marine Association, American Steamship Owners Association, Secretary of Commerce, U. S. Ship Operators Association, Maritime Association of the Port of New York, New York Tow Boat Exchange, Atlantic Coast Shipbuilders Association, Council of American Shipbuilders, Society of Naval Architects & Marine Engineers, American Bureau of Shipping, National Marine Engineers Beneficial Association, Masters, Mates & Pilots, U. S. Chamber of Commerce, National Foreign Trade Council, South Atlantic States Association, American Manufacturers Export Association, National Association of Manufacturers and (Proper Farmers Organization).

GENERAL COMMITTEE

This committee will be honorary, but from which various committees will be drawn. It will have no special duties and is to be composed of officers and Executive Committee members of American Marine Association, government officials of all departments, officers of all associations co-operating, and all other prominent individuals whose activities warrant their appointment on this committee.

Sectional Committees, whose function it will be to assist the Administrative and General Committees in anything they possibly can in their own districts will be formed at once for the following:

- (1) New England District.
- (2) Port of Greater New York, Hudson and inland waterways.
- (3) Delaware River District.
- (4) Hampton Roads—Baltimore to Norfolk.
- (5) South Atlantic States and Gulf.
- (6) Mid-West States and Mississippi River District.
- (7) Great Lakes District.
- (8) Pacific Coast.

BENEFIT TO INDUSTRY

Throughout the entire industry, from the companies who manufacture those things which go into ships to the groups who furnish the cargoes, there is a great need for UNITY OF PURPOSE, and a wonderful opportunity for CO-ORDINATION OF EFFORT, to the end that a definite shipping program may be produced.

It is reasonable and logical to assume that such a program can be carried out successfully, a marked improvement in the industry will result. The benefit derived from this Congress, either to the industry as a whole or to individual companies in it, is proportional to what they put into it.

Contract for \$5,000,000 in New Ships for Oceanic Steamship Company Awaits Favorable Action By Shipping Board

THE placing of contracts for approximately \$5,000,000 worth of new business, involving the construction of two passenger ships and their attendant equipment, may hinge on the action of Edward P. Farley, recently appointed as head of the Shipping Board to take office on June 12, according to information received by MARINE ENGINEERING AND SHIPPING AGE from Washington. The proposed ships have been designed for the Oceanic Steamship Company, of San Francisco, Cal., for the California-Australian service.

The company desires a ten-year mail con-

tract with the government and immediately on accession to its requests is ready to issue plans and specifications to American shipyards for the new steamers. Frederick S. Samuels, general manager of the Oceanic Company and assistant to its president, was in Washington recently and laid the proposition before the Postal and Shipping Board authorities. According to reliable information, Mr. Samuels set forth the facts that the ships would be 500 feet in length, driven by turbo-electric machinery and modernly fitted throughout. They would be built entirely of steel.

Assistant Secretary of the Navy Roosevelt has approved participation of the Navy in the forthcoming Congress and is taking steps to have National Navy Day for all parts of the country fall during the week of the Congress.

Admiral Benson has also given the move-

ment his hearty endorsement and co-operation, which latter is expected to be of special import to manufacturers and operators of Diesel engines, and Admiral Moffat, Chief of the Naval Air Service, will also take an active part, with an especial bearing on the delivery of mail to ships at sea.

Propeller Club of the Port of New York in Session, Whitehall Building, New York City, June 8, 1923.

At this meeting 150 members and guests listened to addresses by Colonel E. A. Simmons, President, American Marine Association; E. J. McCormack, of Moore & McCormack, and Matthew Hale, President of the South Atlantic Maritime Corporation.

Forty-five Boats to Be Constructed for Canal Service

THE construction of five steel power barges and forty steel tow barges from plans and specifications prepared by Kindlund & Drake, naval architects and marine engineers, of 17 Battery Place, New York, is expected to be started in the near future. The boats are to be built for the Interstate Vessel Owners, Inc., of Buffalo, N. Y., for the carrying of bulk cargoes through the state barge canal between Buffalo and New York City. The contract will be one of the largest of its kind ever brought out and the vessels will embody many new features developed by the architects.

Each of the boats will be approximately 100 feet by 21 feet 6 inches by 13 feet; the towing barges to be equipped with internal combustion engines, each developing 375 brake horsepower.

10-Carfloat Order Awarded New York Shipbuilding Corp.

AN order, said to be one of the largest of its kind given since the war, has been placed with the New York Shipbuilding Corporation, of Camden, N. J., by the Pennsylvania Railroad, for ten steel car floats, to cost approximately \$700,000.

This contract will place at the service of the rail line a fleet of modern barges each 350 feet long by 34 feet wide and nine feet in depth, for use in New York harbor. They are to have double tracks for freight cars, the center protected by a steel shed structure to permit handling of freight in all kinds of weather. Ten months is the contract time for completion but the work will be started very shortly and will be rushed to completion.

Newport News Yard Low Bidder for Steel Standard Oil Barge

THE Newport News Shipbuilding Company submitted the lowest bid for the construction of a steel self-propelled oil barge proposed for the Standard Oil Company of New Jersey, at the opening of tenders at 26 Broadway, on May 28. The vessel is to have a length of 220 feet, beam 38 feet, having a capacity of approximately 11,000 barrels of oil. Seven shipyards submitted quotations covering a variety of types of equipment.

Bids Received at Florence, Ala., for New River Towboat

THE United States Engineer Office, at Florence, Ala., received bids on June 11 for the construction of a steam driven stern wheel towboat, as follows: Charles Ward Engineering Works, \$204,000 and Dravo Contracting Company, \$208,000, with an alternative proposition, using stock engine, of \$192,400. Award has not yet been made.

Bids Open July 16 at U. S. Engineer Office, Nashville, Tenn., for Construction of 136-Foot, Steel, Stern Wheel Towboat

THE United States Engineer Office, at Nashville, Tenn., will receive sealed proposals until 11 A. M., on July 16, for the construction of a 116-foot steel hull stern wheel towboat to be delivered at Paducah, Ky. The proposed vessel is to have a length overall of 136 feet 7½ inches, length molded 116 feet, breadth molded 29 feet, mean draft 3 feet 7 inches and is to be built to the American Bureau of Shipping rules. The longitudinal system of framing will be used and the boat will be steered by two rudders.

BOILERS

The main boiler is to be of the marine watertube cross-drum type, with a heating surface of approximately 2,000 square feet and designed for a gauge pressure of 235 pounds per square inch and 150 degrees of superheat. It is to be fitted for burning coal.

PROPELLING ENGINES

The propelling engines are to be of the surface condensing tandem compound type,

Ellicott Machine Corporation Is Low Bidder for Dredge

THE Ellicott Machine Corporation, 1111 Bush Street, Baltimore, Md., with a price of \$288,730, submitted the lowest tender for the construction of the steel hull 6-cubic yard grapple dredge *Wissahickon* when bids were opened by the Department of Wharves, Docks & Ferries of the City of Philadelphia, on May 31.

City of Norfolk Bids \$4,000,000 for Government Supply Base, Including Two Piers, Warehouses and Equipment

NORFOLK, Va. (Special).—The City of Norfolk was the only bidder when bids on the Norfolk Army Supply Base were opened at the War Department on May 22. Four proposals were submitted by the city through City Manager Charles E. Ashburner and Port Director Arthur G. King.

The city submitted a bid of \$4,000,000 for the entire property and offered \$3,950,000 for the property exclusive of the "Barrett tract," on which stands the residence of the commanding officer of the base. A bid of \$3,975,000 was entered for the property with the delayed delivery of certain portions, including a tract of six acres of land and one warehouse the government proposes to reserve for five years for the storage of certain war materials.

A bid of \$5,000,000 was submitted for the whole property, including cranes, locomotives, repair parts, cars and fire apparatus owned by the government, stipulating that payments for the property should be carried over a period of thirty years with interest at 4 per cent, but the interest not to begin until January 1, 1926. This bid specified that the government keep the property in repair until that time.

The War Department has reserved de-

cision on the sale of the property for two days. They are to be designed for a working pressure of 250 pounds per square inch, 150 degrees of superheat at the boiler and a vacuum of 26 inches, the cylinders to be 10½ inches and 18 inches in diameter, respectively, with a common stroke of 72 inches. The condenser is to be cylindrical in shape, two passes with a cooling surface of 800 square feet measured on the outside of the tubes.

The paddle wheel is to be of the radiating fixed paddle type, 16 feet in diameter over buckets, with thirteen buckets 24 inches wide by 18 feet long.

Vacancies for Draftsmen

The United States Civil Service Commission, Washington, D. C., announces the following competitive examinations:

Ship Draftsman. Receipt of application will close July 24, examination to fill vacancy in the Coast and Geodetic Survey, entrance salary of \$130 a month, plus increase of \$20 a month, and vacancies in position requiring similar qualifications.

Design Draftsman (Structural). Applications will be rated as received until August 31, to fill two vacancies at the Naval Operating Base, Pearl Harbor, Hawaii, one at an entrance salary of \$6.80 a day, and the other at an entrance salary of \$8.80 a day, and vacancies in similar positions.

Full information and application blanks may be obtained from the United States Civil Service Commission, Washington, D. C., or the secretary of the board of U. S. Civil Service Examiners at the Post Office Customhouse in any city.

For several weeks the general impression has prevailed that the city would have opposition in bidding for the purchase of the Army Base. The specifications issued by the War Department require that the purchaser pay for the property in twenty-five years, and the city's proposals, with the exception of the \$5,000,000, provided for payment within this time at 5 percent interest.

The property consists of approximately 639 acres of land. There are two covered concrete and steel piers, over 1,300 feet in length, eleven warehouses, 2,079,000 square feet of open storage, fifty miles of track, railroad yards and a score of miscellaneous buildings and other appurtenances.

The Army Base cost about \$23,000,000 built during the war, and the Government estimate of replacement value is in the neighborhood of \$16,000,000. The city's estimate, however, is somewhat below this figure.

The city is ready to finance the purchase of the property. The Port Commission does not feel that the city would be justified in paying a greater price for the property because there would be some doubt as to the ability to pay its own way for the present

Webb Institute of
Naval Architecture
Holds Commencement

THE twenty-seventh annual graduating exercises of the class in naval architecture and marine engineering of the Webb Institute was held in the assembly hall of the college at University Heights, New York, on Thursday, June 7. Commander Stevenson Taylor delivered the opening address in which he compared the present time to that at the end of the Civil War. "There was apprehension then as there is now and in your particular work, although shipbuilding is at a low tide, there is bound to be a turn." The education received at Webb Institute, he pointed out, has been put to good advantage in other lines than shipbuilding by former graduates. It would probably be necessary, he said, for some of this year's class to enter other occupations at least temporarily. It is the usual thing at commencement exercises, Mr. Lewis Nixon declared, to advise the graduates not to make the mistakes that we were advised not to make but to avoid. It is very unusual on the other hand that a class of men entering the profession of shipbuilding is given such splendid encouragement as was furnished by Mr. Winthrop L. Marvin, vice president and general manager of the American Steamship Owners' Association.

OUR SHIPPING TRADITION

We should like to print his address in full but have felt it essential to devote a large part of our space this month to the *U.S.S. United States* which places America again in the enviable position, after a great many years, of owning the largest, the safest and the swiftest ocean liner in the world. These graduates enjoy the remarkable coincidence of the fact that they start their active work at the same time as this vessel begins her career as a passenger liner under the American flag. Shipping has been nationally neglected for a long time and many there are who have come to believe that we can never make good on the sea. If the facts set forth by Mr. Marvin could be broadcasted over the land, this belief would be dispelled once and for all. Some of them are as follows: "Shipbuilding was the very first form of ambitious and successful mechanical effort pursued by the pioneers of our race in the new World. "For years shipbuilding was the most attractive trade which coast-born lads could turn. "Though the British Cunard Company was the oldest on the Atlantic, it did not build its first iron hull until 1855, and it did not launch its first screw steamship until 1862. "Some of the stout iron screw steamers built in American yards 50 years ago are still afloat, so excellent were their materials and workmanship. "The *Ohio*, *Indiana*, *Illinois* and *Pennsylvania*, built by Cramps' shipyard in 1872 and 1873 broke the record for speed then held by the *City of Brussels*.

OUR GREATEST ACHIEVEMENT

"This hasty review brings us down to the present time—to the stupendous achievement of emergency ship construction of 1,400 steel liners—the most remarkable mechanical undertaking the world has ever seen—because in many instances the yards had to be converted to build the ships. "A nation whose naval architects, engineers and builders were unprogressive could never have performed this exploit."

S. S. United States, Reconditioned for Passenger Service on the Great Lakes

S. S. United States
Refitted for Lakes
Passenger Service

REFITTED as a passenger steamer for service on the Great Lakes, the *United States* recently left the Tebo plant of the Todd Shipyards Corporation with forty passengers. She is probably the first vessel

Company. She has been refitted by the Todd Shipyards Corporation from designs prepared by Henry J. Giesow, naval architect, new staterooms, accommodating about 100 passengers, having been added. Considerable deck space has been provided and four dining rooms arranged in the forward part of the vessel.

ORIGINAL SERVICE

Originally built by the Manitowoc Shipbuilding Company, of Manitowoc, Wis., in 1909, to carry passengers between Milwaukee and Grand Haven, the *United States* was elaborately fitted with forty-six staterooms, each named after a state in the Union. The large public rooms were decorated with a series of historical paintings depicting stirring episodes in the nation's history. After six years the vessel was purchased from the Crosby Navigation Company by Col. E. H. R. Green for about \$500,000. The contract for rebuilding the vessel according to the new owner's plans was awarded to the Robins plant of the Todd Shipyards Corporation.

HULL LENGTHENED

About forty feet were added to the hull amidships and the entire interior of the vessel rebuilt. Col. Green desired to retain all home comforts in the new designs and consequently many nautical features were done away with. All overhead beams were concealed and the new rooms laid out on a much larger scale and furnished with remarkable examples of very elaborate period furniture. The living room on the main deck was very spacious, being 26 by 28 feet in size and containing an enormous open fireplace in the after end. The gymnasium was also located on this deck, with suites of Turkish, vapor and shower baths adjoining.

Typical Stateroom

to carry passengers from New York to ports on the Great Lakes. As the steam yacht *United States*, owned by Col. E. H. R. Green, son of the late Hetty Green, this vessel was the largest and one of the most palatial steam yachts in the world. She is 256 feet in length, 41 feet in beam and 16 feet in depth. For the last few years she has been berthed at the Tebo Yacht Basin in Brooklyn. Several months ago she was purchased by the Peninsular and Northern Navigation

Foreign Shipping and Shipbuilding Activities

New French Line Passenger Steamship Cuba

New French Turbine Liner Cuba to Go on St. Nazaire-Havana-Vera-Cruz Route

PARIS, France (Special).—The Compagnie Generale Transatlantique (French Line) has taken delivery of the new passenger vessel *Cuba* built by Messrs. Swan, Hunter and Wigham Richardson at Newcastle-on-Tyne. This twin-screw liner is 476 feet long, 59 feet 9 inches beam, 39 feet 4 inches deep; her deadweight is 6,375 tons on 24 feet 7 inches draft. Her approximate gross tonnage is 8,850 tons.

The propelling machinery consists of two sets of Rateau steam turbines driving the propeller shafts through double reduction gearing. Owing to the inconveniences experienced in service with several vessels equipped with ordinary double reduction gearing in the course of the last year, the owners decided that in lieu of Parsons gearing, as was originally designed, Westinghouse gearing with floating frame should be fitted, and the *Cuba* is the first vessel equipped with this design of gearing in this country.

Quill shaft drives have thus been adopted between turbines and first reduction pinions as well as between first reduction wheels and second reduction pinions. The nickel steel pinions were manufactured by Messrs. Armstrong, Whitworth and Company. The power developed is 6,500 horsepower normal and 9,000 horsepower maximum.

Steam is supplied by eight boilers. The oil burning plant was supplied by the Wallsend Slipway Engineering Company. The boilers are capable of being rapidly converted to coal burning if necessary. Arrangements have been made for the ship to bunker at Havana where in spite of the rate of exchange the cost of oil fuel is considerably lower than the prices current in French ports.

The *Cuba* has been built to the highest class of the Bureau Veritas, the French ship classification society. She has been designed to comply with the regulations on safety at sea laid down at the 1914 International London Conference although these new reg-

ulations have not so far been definitely ratified by French Parliament and are not yet enforceable.

Passenger accommodations are provided for 8 de luxe, 273 first class, 50 second class, 76 third class passengers, 176 cabin emigrants and 504 emigrants in posts. The total of the passengers thus works out to 1087.

The decoration of the *Cuba* has received special attention from the owners and she will rank among the finest modern passenger vessels in this country. The decorative work has been carried out by three well-known French firms of ship decorators (Billard et Rousseau, Leglas Maurice et Jamin, and Marc Simon). The leading feature of the decoration of this vessel is an example of the French modern art, and this explains why reproductions of several pieces of furniture and decorative work of this steamer have been shown at several important art exhibitions in Paris.

The *Cuba* ran her speed trials on April 12: a maximum speed of 17 knots was attained and the service speed of the ship is expected to be about 15.75 knots.

The *Cuba* is to run on the Saint-Nazaire, Coruna, Havana, Vera-Cruz route, together with the two other liners *Espagne* and *Flandre*. She sailed on her maiden trip on May 5.

Turbine Blades of Monel Metal

LONDON, England (Special).—At the recent conference at Sheffield on the subject of corrosion, a number of the industrial uses of monel metal were discussed. In regard to turbine blading, it was suggested that any troubles experienced with monel metal were not due to any inherent inability of the metal to withstand the stresses to which it is subjected. If the preparation of the alloy and the heat treatment is right, it was asserted that users could rely that metal specially prepared for turbine blades would have a tensile strength of 40 tons per square inch and an elongation of 26 percent. Moreover they would have the additional advantage that at temperatures as high as 750 degrees Fahrenheit the metal would not suf-

fer to any appreciable extent in tensile strength and modulus of elasticity.

A Five-Bladed Propeller

LONDON, England (Special).—It has been recently learned that a five-bladed screw propeller has been manufactured by Bull's Metal and Melloid Company, Yorker, England, to the order and specification of a Continental firm of engineers. It is not known for what purpose this propeller has been made but it is a solid wheel 18 feet 5 inches in diameter and it weighs 9 tons 15 hundredweight. The propeller has been made from the firm's special metal.

Single Reduction Geared Turbines for S. S. De Grasse

PARIS, France (Special).—I reported in my article which appeared in the May issue of MARINE ENGINEERING AND SHIPPING AGE that the French Line were considering the adoption of turbo-electric drive for their passenger vessel *De Grasse* which is under construction at the yards of Messrs. Cammell, Laird, at Birkenhead, and will be placed in service on the Havre-New York line.

This scheme has now been definitely rejected by the owners for several reasons: the chief reason lies in the fact that France has had so little experience with the electric drive, there being only two French vessels so equipped. Second: Very few French marine engineers are acquainted with this mode of ship propulsion and it would be necessary to provide special training for them. Third: The French Line considered it not advisable to make a first experiment of this mode of propulsion on a vessel placed into service on the mail line between Havre and New York.

It is thus likely that the adoption of turbo-electric drive will be reserved for vessels engaged in services which do not involve so much reliability in the running of vessels

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Steamer Drydocked, Chester, Pa.—The steamship *io* has been drydocked at the Sun Shipyard, Chester, for miscellaneous repairs.

Ferryboat Docked, Portsmouth, Va.—The ferryboat *Porpoise* has been docked at the Portsmouth Navy Yard for necessary repairs.

Overhauling, Toledo, Ohio.—The steamer *H. S. Wilkinson*, damaged in collision in the Great Lakes, has been taken to Toledo for extensive repairs.

Tug Overhauling, Portland, Ore.—The *F. A. Douty* has been drydocked to have a new wheel fitted and undergo annual inspection.

Steamer Repairs, Ashtabula, O.—The steamer *May*, with about six damaged plates, has been docked for repairs at the Ashtabula yard.

Steamer Repairs, Detroit, Mich.—The steamer *Conneaut*, which lost her shoe and rudder recently, has been drydocked at Detroit for repairs.

Tanker Drydocked, Chester, Pa.—The American tanker *Sun*, owned by the Sun Oil Company, has been drydocked at the Sun Shipbuilding Company, Chester.

Repairs, Portland, Ore.—The crippled schooner *Red Baxter* was towed to Portland recently to be drydocked. She lost her propeller on her way up the coast.

Freighter Drydocked, Chester, Pa.—The Furness-Reserve freighter *Portuguese Prince* has been drydocked at the Sun Shipbuilding & Drydock Company for repairs.

Installation of Stern Frame, San Francisco, Calif.—The Norwegian motorship *Handicap* has been moved on the Bethlehem ways to have a new stern frame installed.

General Overhauling, Buffalo, N. Y.—The passenger steamship *Tionesta* is in the Buffalo Drydock where her bottom painted and a general inspection and overhauling.

Overhauling at Navy Yard, Philadelphia, Pa.—The Pennsylvania State schoolship *Annapolis* will undergo annual overhauling at the Philadelphia Navy Yard.

Damage Repairs, Portland, Ore.—The steamer *Malta Mahony* has been lifted for repairs due to damage caused when she upset recently with too heavy a deck load.

Bids Requested, Philadelphia, Pa.—The Reading and Iron Company is asking bids for the barge *Alata*, now lying on the Maine coast, to be sold and where it is.

Steamer Drydocked, Superior, Wis.—The steamer *Island*, which hit the crib at the entrance to Neeshier Cut, has been placed in drydock at the Superior for repairs.

Turbine Gear Repairs, Philadelphia, Pa.—The contract for repairing the turbine gears of the Italian steamship *Tuscola* has been awarded to the John A. Leary Iron Works, Philadelphia.

General Overhauling, San Francisco, Cal.—The steamship *Agnes Dollar* was taken to the General Engineering yards for drydocking, general overhauling, and to have her tailshaft drawn.

Steamer Drydocked, Chester, Pa.—The British steamship *Tartar Prince* has been drydocked at the yards of the Sun Shipbuilding and Drydock Company, Chester, for painting and inspection.

Coast Guard Cutter Repairs, Oakland, Cal.—The United States Shipbuilding Company submitted the lowest estimate for repairs on the United States coast guard cutter *Cahokia*, with a price of \$1,178.

New Boilers, Portland, Ore.—The Commercial Iron Works received the contract for the removal of Scotch marine boilers aboard the government dredge *Clatsop* and will install new pipe boilers.

Fireboat Repairs, Jacksonville, Fla.—The city fireboat *John B. Callahan* has been hauled out on the Merrill-Stevens drydock for slight repairs, the Merrill-Stevens Company having submitted the lowest bid.

Steel Ship Launched, Chicago, Ill.—The new freighter *Herbert N. Heath*, of 120 tons, has been launched. She is of steel construction and steam power, is 65 feet long, 22 feet wide, and draws eight feet.

Tug Drydocked, Portland, Ore.—The tug *George H. Mendell* was recently placed on the Portland drydock to ship a new propeller and also to have her stern bearing inspected, cleaning and repainting of the hull.

Lighter Launched, Baltimore, Md.—Booz Brothers recently launched the second of an order for two harbor lighters for the Cottman Company, the dimensions being 80 feet long, 24-foot beam, and 7 feet 6 inches deep.

Repairs Completed, Canal Zone.—The tanker steamer *Miskianza* left the Canal Zone early last month after the completion of repairs amounting to about \$13,000. The ship is being operated by Walker & Daly, New York.

Steamer Repairs, San Francisco, Cal.—At the opening of bids for the repairing of the steamer *West Chochea*, operated by Struthers & Barry, the Crowley Shipbuilding Company, of San Francisco, Cal., was low bidder with a tender of \$1,470.

Low Bidder, San Francisco, Cal.—With a price of \$835 Smith & Scanlon was low bidder for voyage repairs on the Pacific Mail intercoastal carrier *Ecuador*. Other bids were: United Engineering, \$945; Bethlehem, \$1,025; Moore's, \$1,098, and Crowley's, \$1,250.

Contracts Awarded, Mobile, Ala.—The Alabama Drydock & Shipbuilding Company was awarded the following contracts: steamship *Hulaco*, for inspection, painting, drydocking and overhauling; and the bay steamer *Crescent City*, for cleaning and painting bottom.

Low Bidder, Oakland, Cal.—At the opening of tenders for voyage repairs to the Swayne and Hoyt government-operated freighter *West Jappa*, the Hanlon Shipyard submitted the lowest bid. The prices were: Hanlon's, \$2,688; Moore's, \$2,738, and Bethlehem, \$2,775.

Overhauling and Repairs, Buffalo, N. Y.—The Oldman-Magee Boiler Works has transformed the steamer *Usono*, belonging to White-Gratwick & Mitchell from a trunk-hatch type into a five-hatch type, giving her at the same time a general overhauling and repairs.

Tug Overhauling, Staten Island, N. Y.—The tug *Howard C. Moore*, of John E. Moore Company, is undergoing a general overhauling at the Staten Island Shipbuilding Company's Port Richmond yard. Foster waste heat type superheaters for 75 degrees superheat will be installed.

Shipyard Activities, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation received the following contracts: Matson steamer *Mau* and the American-Hawaiian steamer *Ohioan*, for cleaning, painting and drydocking; the *Idaho*, *Water Nymph*, *Pennsylvanian* and tug *Payson*, for miscellaneous repairs and painting.

Diesel Dredge Launched, Portland, Ore.—The Portland Shipbuilding Company recently launched the first Diesel electric dredge yet floated in waters of the United States, so far as records are known to the Long-Bell Lumber Company. The dredge is the *Texas*, a wooden-hull type.

Bids on Windlass, Staten Island, N. Y.—Sealed proposals were received by the Superintendent of

Lighthouses, 3rd District, Staten Island, N. Y., on June 11, for one steam capstan windlass, to be delivered at tidewater at Key West, Fla., accessible to the tackle of a lighthouse tender.

Estimate on Engines, Portsmouth, Va.—The Bureau of Engineering has designed a new type of gasoline engine, a detailed description of which has been furnished the navy yard with the request that the yard submit detailed estimates as to time and cost for manufacture of fifty of them.

New Ferryboat Planned, San Francisco, Cal.—The officials of the Northwestern Pacific are reported as planning to build a ferryboat, to be 280 feet long and 72 feet beam, and of the latest type. Several shipyards are now engaged in drawing plans for submission to the Northwestern Pacific Company.

Miscellaneous Repairs, Buffalo, N. Y.—The Ashtabula & Buffalo Dock Company has finished installing a new tank top in the steamer *Venus* and has placed new furnaces and made other repairs on the steamers *Tarus*, *Hemlock* and *Conopus*, all belonging to the Interlakes Steamship Corporation.

Steamers Drydocked, Great Lakes.—After having grounded near Bailey harbor, the steamer *Alex B. Uhring* was placed in drydock at Milwaukee with twenty-nine damaged plates, five of which will be renewed. Steamer *Back Bay*, formerly the *Burlington*, has been docked at Cleveland for repairs to bottom damage.

Miscellaneous Repairs, Chester, Pa.—The Atlantic Refining Company's tanker *J. E. O'Neill* has been drydocked at the Sun Shipbuilding and Dry Dock Company for miscellaneous repairs. The Merchants' and Miners' Transportation Company's passenger steamship *Ontario* has also been drydocked at the same company's yards.

Steamship Conversion, Brooklyn, N. Y.—The *Montpelier*, one of the steamers operated by the United American Lines, has been taken to the Crane Drydocks, Brooklyn, for reconditioning as an oil-burning ship, after which she will be placed in the recently established service between Pacific coast ports and Europe.

Contract Awarded, San Francisco, Cal.—The General Engineering and Dry Dock Company received the contract for voyage repairs to the Pacific Mail liner *President Wilson*, at a price of \$4,018. The other bids received were: United Engineering, \$5,177; Crowley's, \$5,342; Moore's, \$5,400, and the Bethlehem Shipbuilding Corporation, \$5,596.

Scout Cruiser Passes Trial, Puget Sound.—The second cruiser to leave the Tacoma plant of the Todd Shipyards Corporation, the United States scout cruiser *Milwaukee*, recently passed a successful trial trip, making a speed of 35 knots or 40.3 statute miles per hour. During the trial the *Milwaukee*'s engines developed 97,000 shaft horsepower.

Contracts Awarded, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company has been awarded the following contracts: Steamship *Edgefield*, chipping, scaling, painting, tail shaft examination and other miscellaneous repairs; tug *Buzzard*, drydocking and installing new propeller; tug *Nimrod*, boiler repairs, and United Fruit Company's steamship *Venator*, repairs.

Shipyard Activities, Oakland, Cal.—The Moore Drydock Company has been awarded the following work: Installing of a new tailshaft on the steamer *Dewey* and various repairs on the transport *Dix*, ferryboat *Cazadero*, motorship *La Merced*, the latter being equipped with new masts and other general reconditioning preparatory to departing in the off-shore trade, and the schooner *Fox*.

Repair Contract, Kearny, N. J.—A contract for the drydocking and general repairs and the putting into condition of approximately thirty vessels of the Submarine Boat Corporation, operated by the Transmarine Corporation, in connection with the Port Newark development, has been awarded to the Federal Shipbuilding Company, of Kearny, N. J. It is

understood that the contract will involve over \$50,000 and the vessels are to be taken to the yard at the rate of one per week.

New Steamer, South Jacksonville, Fla.—George W. Gibbs, Jr., president of the Gibbs Gas Engine Company, has announced that the company has obtained the contract for the construction of a new steamer for the Virginia-Carolina Chemical Company, of Wilmington, N. C. The steamer will be 65 feet long, have two decks, and will be equipped for passenger and freight service. It will be used at Richmond, Va.

Shipyard Activities, Oakland, Cal.—The Coast Guard cutter Golden Gate is being repaired by the Hanlon Shipbuilding and Drydock Company, at a price of \$281. The yard was also low bidder on repairs to the West Prospect, operated for the Shipping Board by Struthers & Barry, the bid submitted being \$739. The lumber carrier Helen P. Drew and the pilot boat Gracie S. are at the Hanlon yard for general overhauling.

Ship Repair Contract, San Francisco, Cal.—The General Engineering and Dry Dock Company, San Francisco, Cal., received the contract for miscellaneous repairs on the Pacific Mail liner President Lincoln. The following tenders were received: General Engineering & Dry Dock Co., \$3,316; Moore Dry Dock Co., \$3,554; Bethlehem Shipbuilding Corp., \$3,810; Hanlon Dry Dock & Shipbuilding Co., \$3,857; United Engineering Co., \$3,945.

Extensive Repairs, Manitowoc, Wis.—The steamer Ann Arbor No. 4, which went to the bottom at the entrance to Frankfort harbor last February has been placed in drydock at Manitowoc. She has eighty-nine shelf plates and twenty-six deck plates damaged, her bottom being shoved up 10 inches from bilge to bilge for fifty feet. The steamer is to be at the shipyard for about five weeks and repairs will cost approximately \$100,000.

Repair Contracts, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was awarded the following repair work: Standard Oil tanker K. R. Kingsbury, overhauling; the Chiore, final adjustment preparatory to speed test; the La Purisima, general overhauling; tanker Levant Arrow, to have a new furnace installed in her boilers; the Mystic and freighter American, both of the American-Hawaiian fleet, for general repairs and cleaning.

Contracts Awarded, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation tendered the lowest bid for drydocking, cleaning, painting and general repairs to the army transport Meiggs, the following bids having been received: Bethlehem, \$3,925, and Moore Drydock Company, \$4,140. The Bethlehem Company was also low bidder for the general overhauling of the Associated Oil tanker W. S. Porter, with a bid of \$2,395, the Moore Company submitting a tender of \$2,424.

Ship Repairs, Kearny, N. J.—At the opening of tenders for the work of general repairs on the Montebello, the Bethlehem Shipbuilding Corporation was low bidder. The bids were: Bethlehem, \$11,803; Hanlon's, \$13,649; General Engineering, \$13,923; Moore's, \$14,651, and the Main Iron Works, \$15,699. On the Shipping Board steamer Bearport the bids were: Bethlehem, \$11,803; Hanlon's, \$13,649; General Engineering, \$13,923; Moore's, \$14,951, and the Main Iron Works, \$15,699.

Shipyard Activities, San Francisco, Cal.—The Crowley Shipyard was low bidder for carrying out miscellaneous repairs and cleaning of the Swayne & Hoyt Government operated steamer President Harrison and the quarantine tug Albatross. The bids submitted on the President Harrison were: Crowley's, \$175; General Engineering, \$211, and Bethlehem, \$250. The tenders on the Albatross were: Crowley's, \$635; General Engineering & Drydock Company, \$688, and William Cryer, \$702.

Construction Contract, Portland, Ore.—The contract for the construction of the hull for a new Snake river sternwheel steamer for the O. W. R. & N., of Portland, Ore., has been awarded to Supple & Martin. The new vessel, which is to replace the steamers Lewiston and Spokane, destroyed by fire last year, is to represent an outlay of about \$65,000 and will be 160.2 feet long, with a beam of 35 feet and depth of hold of six feet. Machinery saved from the burned steamers will go into the new vessel.

Radio Contract, San Francisco, Cal.—District Manager Linton of the United States Shipping Board in Seattle has advised A. Y. Tuel, manager of the San Francisco offices of the Federal Telegraph Company, that permission to install a Kolster radio compass and position finder on the Admiral-Ortalian liner President McKinley had been received and it is stated that if the installation proves suc-

cessful after a round trip to the Orient all of the 535-type vessels out of Seattle will be similarly equipped.

Shipyard Work, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company, Mobile, has been working on the following contracts: Steamship Berterton, extensive turbine and condenser repairs, etc.; steamship Bayou Chico, stern tube rebushed, rivets renewed and other minor repairs; steamship Tauhate, minor work about boilers and deck winches; U. S. D. B. Boat L-58, renewal of bad planking, caulking all seams and renewal of entire copper sheathing on bottom and rolling chocks and rudder; and the steamship Quabbin, necessary repairs.

Vehicular Ferry, New York.—The Pennsylvania Railroad has placed in commission a ferryboat reconditioned to handle exclusively the vehicular traffic between New York City and Jersey City. The railroad has gradually converted its entire ferryboat fleet of eight boats into what is termed "double team gangway boats," on which the lower deck is reserved for vehicles and the upper deck for passengers. This reconditioning has doubled the vehicular carrying capacity so that sixty passenger automobiles can be accommodated on each trip across the river.

Yacht Refitted, Brooklyn, N. Y.—The steam yacht United States, owned by Col. E. H. R. Green, has been refitted as a passenger ship to carry passengers from New York to ports on the Great Lakes. The vessel is 256 feet long, 41 feet beam and 16 feet depth, and was one of the largest and most palatial steam yachts in the world. About forty feet have been added to the hull amidships and the entire interior of the vessel has been rebuilt. Several months ago she was purchased by the Peninsular & Northern Navigation Company. She has been refitted from designs prepared by Henry J. Gielow, naval architect, by the Todd Shipyards Corporation, new staterooms accommodating about 100 passengers, having been added.

Conversion Jobs Pending.—It has been learned that the O'Boyle Lighterage Company is figuring on taking the McIntosh & Seymour Diesel engine out of their wooden oil tanker J. F. Penrose, purchasing a Lake-type steel cargo boat from the Shipping Board and installing the engine therein. The Lake-type boats are of 3,500 deadweight tons capacity. The carrying out of this contract depends upon a satisfactory settlement with the Shipping Board with regard to price. Other reports in marine circles indicate that a large shipping company, whose stock is owned mainly by foreign interests, has definitely decided to convert several Shipping Board vessels to motorships, but so far has not been able to reach satisfactory agreement with the Shipping Board.

Extensive Repairs, Mobile, Ala.—The steamship Sapulpa, to be renamed the Cape Ann, has been placed on the docks of the Alabama Dry Dock & Shipbuilding Company. She was recently purchased by the Pure Oil Company. The work to be done on the vessel includes the following: Cleaning, painting bottom from keel to deep load line, examination of tail shaft, top sides scraped and painted, etc.; the inside work including testing out and repairing entire electric, telephone and fire alarm system and renewal of all defective fixtures, boilers cleaned, main and auxiliary condensers tested out, tubes cleaned and proven tight, refrigerating system thoroughly cleaned, charged and tested, ice machine thoroughly overhauled, and various other miscellaneous repairs.

New Fireboat, Los Angeles, Cal.—The Los Angeles Harbor Commission and Chief Ralph J. Scott are laying plans for added fire-fighting equipment at Los Angeles Harbor, both land and water apparatus. A new fireboat and engine company are to be located on the Wilmington waterfront, the center of the port's industrial growth. Chief Scott has also announced that fireboat No. 1, now stationed on the main channel at the harbor, will be remodelled. The gas engine, at present propelling the craft, will be replaced by a 300-horsepower full Diesel engine of the latest type, at a cost of approximately \$33,000. A tower will be constructed on the boat, so that the crew of the craft may be able to fight steamer and dock fires with maximum efficiency, the boat's two pressure heads being joined to a single line, operated from the top of the tower.

Floating Equipment, Wilmington, N. C.—The United States Engineer Office, Wilmington, N. C., received bids on June 4 for the construction of twenty-eight steel hulls to replace certain floating equipment now used by the Federal Government in local river and harbor improvements and mainte-

nance work. One of the vessels to be built for the Engineer Department is a new hull for the snag boat H. G. Wright, now used for removing obstacles from local waterways, two will be barges for conveying water and materials for dredges and other craft engaged in Government work on the river, and twenty-five will be catamarans for the suction dredge Henry Bacon, at work on the lower Cape Fear. The catamarans are to be small floats for supporting a large steel pipe through which mud and material pumped from the river channel by the dredge Bacon is conveyed to shallow water near the river bank. These floats are to replace worn-out catamarans of wood.

SHIPYARDS AND DRYDOCKS

Shipyard Purchased, Oakland, Cal.—David Blankenhorn, Los Angeles business man and member of the syndicate acquiring the industrial property, announced the purchase of the Liberty Shipbuilding Yards in Oakland, containing more than 170 acres. The title on the land was obtained from the Shipping Board by a group of Los Angeles and San Francisco financiers, including Mr. Blankenhorn, president of David Blankenhorn, Inc., investments; William F. Humphreys, attorney and president of the Old Mission Portland Cement Company in San Francisco; Henry Rosenfeld, executive of the Insurance Exchange and Firemen's Fund Insurance Company of the northern city, and James Tyson, president of a number of lumber concerns, including the Consolidated Lumber Company. During the war the yards were under the management of the Emergency Fleet Corporation, and many large sea-going vessels were constructed there. It is proposed to divide the yards into units and to sell them for industrial purposes to organizations who intend to locate in that section.

NEW INCORPORATIONS

The Nautilus Steamship Corporation of Manhattan has increased its capitalization from \$700,000 to \$800,000.

The Gaston, Williams & Wigmore Steamship Corporation, a Delaware corporation, has surrendered its authority at Albany.

The Lancaster Steamship Corporation of Manhattan, owning the steamer Lancaster, has increased its capitalization from \$300,000 to \$350,000.

Banks Rigging Company, of Brooklyn, ship riggers, capital \$10,000, chartered at Albany. Incorporators: T. M. Reid and E. M. Banks.

The International Salvage Corporation, of Brooklyn, incorporated under Delaware laws, has increased its capitalization from \$200,000 to \$500,000.

The General Marine Salvage Corporation, capital \$750,000, incorporated under Delaware laws. Corporation Trust Company, of America, registrars.

The New York, Atlantic City and Philadelphia Steamship Company, capital \$2,000,000, incorporated in New York. The beginning of this line will give Philadelphia two services to New York.

The Mexican, American Fruit & Steamship Corporation, capital \$12,000,000, organized under Delaware laws. Incorporators: F. J. Porter, Montgomery B. Angell and Otis T. Bradley, of New York.

PORT IMPROVEMENTS

Ferry Docks, Windsor, Ont.—Detroit & Windsor Ferry Company plans to extend and improve docks at Windsor, wood pile, concrete and timber. \$200,000.

Harbor Improvement, Olympia, Wash.—Thurston County voted on June 26 on improving harbor, including channel 35 feet deep, at low water, with turning basin, also tidelat and fill.

Dredging Bids Rejected, New York, N. Y.—Commissioner of Docks, Pier "A," North River, rejected bids for dredging between West 97th and West 99th streets. Contract 1799. Will re-advertise.

Levee, Stockton, Cal.—Western-Pacific Railroad, Mills Building, San Francisco, awarded the contract for a two-mile levee south of Stockton, 175,000 cubic yards, to W. A. Betchel, 625 Market street, San Francisco.

Sca Wall, Vicksburg, Miss.—Sealed proposals will be received until July 2, at City Hall, for a concrete wall along river front. Miller-Butterworth Company, 624 Southern Trust Building, Little Rock, Ark., engineers.

Rebuilding Dock, Superior, Wis.—Pepard & Fulton, 217 Board of Trade Building, was awarded the contract for rebuilding ore dock No. 2, here, by the Great Northern Railway, Railway Building, St. Paul, Minn.

Harbor Development, Los Angeles, Cal.—City voted \$15,000,000 bonds for development of harbor, including docks, wharves, warehouses, elevators, piers, railroad terminals, channels, breakwaters, jetties, dikes, etc.

Grain Elevator, Sarnia, Ont.—A grain elevator, steel and concrete, is planned on waterfront, here, by Hunt Brothers, Ltd., care of C. R. Hunt, Nightingale avenue, London, at \$1,500,000. Prices are wanted on material and equipment.

Pier, etc., Boston, Mass.—The City of Boston awarded the contract for rebuilding piers, bulkhead and dolphins for East Boston ferry, 100,000 feet more or less of piles and timber, to Rendle Stoddard Co., Main street, Chelsea. \$31,700.

Contract Awarded, Meridian, Cal.—The contract for making 141,313 foot ditch and lateral excavation, 18,000 foot main canal excavation, etc., was awarded to H. T. Reupke, Box 421, Los Banos, by Reclamation District 70. Price, \$33,222.

Piers and Wharf, Pearl Harbor, H. T.—Specification 4799. Bids will be received by the Bureau of Yards and Docks, Navy Department, Washington, D. C., for reinforced-concrete concrete piers and wharf at Submarine Base, Pearl Harbor.

Ferry House, New Orleans, La.—The Board of Port Commissioners, New Court Building, is having plans prepared for a reinforced-concrete ferry house, Canal street, New Orleans. \$100,000. A. Owen, Interstate Bank Building, architect.

Grain Elevator, Montreal, Que.—Harbor Commissioners awarded the contract for an extension to grain elevator "B" at Windmill Point, providing additional handling capacity of 1,272,000 bushels, to E. G. M. Cape Company, Ltd., 10 Cathcart street.

Contract Awarded, Eudora, Ark.—Eudora Western Drainage District of Chicot County awarded the contract for 3,543,000 cubic yards of excavation and 9.1 mile channel clearing, Schedule D, to McWilliams Company, Inc., Exchange Building, Memphis, Tenn.

Elevator, Indianapolis, Ind.—Perins Mills, Inc., Emerson avenue and Pendleton Pike, plans five-story, 150 by 500 feet, and 1-story, 120 by 200 feet elevator, reinforced-concrete, Pendleton Pike. \$50,000. Engineering Investment Company, care of Guyer, engineers.

Contract Awarded, Detroit, Mich.—Public Lighting Commission, Atwater street, awarded a contract for constructing a wharf and dock, reinforced-concrete, at side of proposed lighting plant, to Greil Brothers, 100 Bulkhead E, Walnut street, Green Bay, Wis., \$417,400.

Dredging, Oakland, Cal.—The Alaska Packers' Association, Wells Fargo Building, San Francisco, awarded the contract for dredging in Oakland Estuary, 1,000,000 to 1,500,000 cubic yard excavation, to American Dredging Company, 255 California street, San Francisco.

Dredging, Manitowoc, Wis.—The contract for dredging Manitowoc River has been awarded to Simmons & Connell Dredge Company, 10 South La Salle street, Chicago, 23,000 cubic yards of dredge pan, \$2.30 per cubic yard and 70,000 cubic yards of softer material, \$0.44.

Woodwork for Shed, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, at their office, Suite 200, New Court Building, on June 28, for furnishing and erecting woodwork for the Market street shed. Requisition E. D. 13450.

Levees, Yuba City, Cal.—Reclamation District No. 40, care of State Reclamation Board, Forum Building, Sacramento, awarded a contract to Callahan Construction Company, City National Bank Building, Wichita Falls, Tex., for constructing levees, Yuba City, at \$500,000 or more.

Levee, etc., Prairie du Chien, Wis.—Crawford Company Levee and Drainage District, Court House, had plans prepared for 1,498,000 cubic yards of river levee work, 1,265,000 cubic yards bluff diversion, 278,200 cubic yards of drainage ditches, 22 miles transmission lines, pumping plant, etc.

Belt Conveyor, Memphis, Tenn.—Sealed proposals will be received at the office of the Mississippi River Commission, First and Second Districts, 1006 McCall Building, Memphis, Tenn., until 11 A. M., July 10, 1923, for furnishing and delivering one (1) belt conveyor. Further information on application.

Dock Front, etc., Conneaut Harbor (Conneaut, P. O.), Ohio.—Bids were received at the office of H. T. Porter, chief engineer, Bessemer & Lake Erie Railroad, Greenville, Pa., on June 25, for a reinforced-concrete dock front and dredging channel between present dock front and new dock front, etc., here.

Levee, New Orleans, La.—Louisville & Nashville Railroad, 10th street and Broadway, Louisville, Ky., and Southern Pacific Railroad, 165 Broadway, New York City, plan levee along Mississippi River, near New Orleans. \$100,000. G. R. Smiley, 10th and Broadway, Louisville, Ky., chief engineer of construction.

Freight Shed, New York, N. Y.—J. H. Delaney, Commissioner of Docks, Pier "A," foot of Battery Place, awarded the contract for a new freight shed on pier at foot of Roosevelt street, East River. Brooklyn Bridge Improvement, Manhattan Borough. Contract 1809, to McHarg Barton Company, 1328 Broadway, \$82,000.

Contract Awarded, Brooklyn, N. Y.—J. H. Delaney, Commissioner of Docks, Pier "A," foot of Battery Place, North River, New York, awarded the contract for dikes and dredging channel between Mill Basin and Paerdegat Basin, Jamaica Bay. Contract 1797, to Arundel Corporation, foot of Fulton street, \$172,220.

Woodwork for Grain Elevator Plant, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans at their office, Suite 200, New Court Building, on June 14, for furnishing and erecting woodwork for the grain elevator sacking plant shed and bins. Requisition E. D. 13517.

Pier, Charleston, S. C.—Sealed proposals were received by the Port Utilities Commission of Charleston, S. C., at its office, Room 712, People's Building, on June 14, for constructing with creosoted piles a pier at Market street, and a wharf at Columbus street, Charleston, S. C. Further information on application.

Pier, Charleston, S. C.—Sealed proposals were received by the Port Utilities Commission of Charleston, S. C., Room 712, Peoples Building, until noon, June 1, 1923, for constructing a pier (exclusive of earth fill) on Town Creek, Charleston Harbor. Further information on application. H. M. Gallagher, general manager.

Pier Development, Sanford, Fla.—W. T. Donnelly, consulting engineer, of 17 Battery Place, New York, has issued plans and specifications for pier development at Sanford, on behalf of the city. Bids returnable June 18. The work is expected to cost about \$70,000, being part of a scheme to ship Florida fruit by water from inland points to New York.

Creosoted Timber, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Orleans Court Building, on June 7, for furnishing approximately 520,000 feet board measure creosoted timber, and 1,228 creosoted piles in 70, 75, 80 and 85 foot lengths. Requisitions, ED-13518 and ED-13519.

Reconstruction of Wharf, New Orleans, La.—The Board of Commissioners of the Port of New Orleans, Suite 200, New Court Building, received sealed proposals on June 7 for the reconstruction of the Celeste Street Wharf and for the raising and rat-proofing of the remainder of the landing in rear of the same. Requisition, ED-13471. J. H. Walsh, general manager.

Dredging, Toms River, N. J.—Bids are desired by the Board of Commerce & Navigation, State House, Trenton, for (1) finishing incomplete contract for dredging canal, 75-foot bottom width, edge of Manasquan River; (2) removing remainder of material to make canal of 100-foot bottom width; (3) dredging channel Manasquan River, 100-foot bottom width, as far as funds will permit, \$70,000. V. Gelineva, director.

Wharves, etc., Beaumont, Tex.—The Houston Construction Company, 3102 McKinney avenue, Houston, was awarded the contract for 75,000 cubic yards of dredging and fill, \$16,500; 4,500 square yards of porous backing, \$2,700; 45 cubic yards of mass concrete, \$810; 1,400 lineal feet of wharf platform, \$119,000; 1,500 lineal feet of bulkhead, \$127,500, and 300 tons of stone riprap, \$900; total \$267,410.

Bond Issue, Fort Pierce, Fla.—The Board of County Commissioners called an election on a proposed \$220,000 bond issue for improvements to the Fort Pierce inlet, on June 25. The proposed inlet improvements include the deepening of the channel to a depth of fourteen feet and extension of both north and south jetties easterly and westerly to provide sufficient protection from the action of the waves and storms.

Sheet Metal Work, etc., New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Court Building, on June 21, for one contract for furnishing and erecting sheet metal work and glazing, and another contract for furnishing and erecting downspouts at the new sacking plant of the public grain elevator. Requisitions ED-13542-downspouts, and ED-13543-sheetmetal work and glazing.

Earthwork, St. Louis, Mo.—The La Crosse Dredging Company, Plymouth Building, Minneapolis, Minn., was awarded two contracts by the Mississippi River Commission, 1311 International Life Building, as follows: 645,000 cubic yards of earthwork in Iowa River-Flint Creek Levee District 16, Iowa, and 300,000 cubic yards of earthwork in Louisiana County Levee District 15, Iowa; \$0.28 per cubic yard, total \$180,000, and \$0.1875 per cubic yard, total \$56,250, respectively.

New Warehouse, Tampa, Fla.—According to recent announcement, work is to start on July 1 on the new warehouse of the Swann Terminals. The building is to include every modern facility used in terminal warehouses, to be five stories high, contain more than 300,000 square feet of floor space and will cost approximately \$500,000. Space will be provided for permanent tenants in various wholesale lines. The building will have ample dock, wharf, and railroad facilities.

Dredging, Canada.—The Department of Public Works, Ottawa, Ont., awarded the following contracts to Soo Dredging and Construction Company, Saulte Ste. Marie, Ont., dredging at Saulte Ste. Marie, Ont., \$18,200; Randolph-MacDonald Company, Crown Office Building, Toronto, Ont., at Bowmanville, Ont., \$6,500; Frontenac Dredging Company, Kingston, Ont., at Port Hope, Ont., \$6,500; Dufresne & Marchelidon, Three Rivers, Que., at Nicolet, Que., \$10,000, and St. Pierre, Que., \$8,000; Lachance, Ltd., 99 Dalhousie street, Quebec, Que., at Riviere du Loupe, Que., \$6,000.

Steel Framing, etc., New Orleans, La.—Sealed proposals will be received by the Board of Commissioners of the Port of New Orleans, at their office, Suite 200, New Court Building, until 3:00 P. M., July 5, 1923, for furnishing and erecting at Poland Street Landing under two separate contracts: A—Structural steel framing for shed, approximately 216 tons (Requisition E. D. 13534); and, B—Steel rolling doors, approximately 4,560 square feet (Requisition E. D. 13555). Requisitions E. C. 13554 and E. D. 13555.

GOVERNMENT WORK

Dredging, Bids Rejected, Baltimore, Md.—U. S. Engineer, Baltimore, rejected bids for dredging in Chabonne Harbor.

Superstructure, Detroit, Mich.—U. S. Engineer, 337 Federal Building, rejected bids for superstructure on west center pier, St. Marys Falls Canal.

Dredging, San Diego, Cal.—U. S. Engineer, Central Building, Los Angeles, received bids, June 2, for dredging in San Diego Harbor, 480,000 cubic yards.

Dredging, Providence, R. I.—U. S. Engineer Office, Providence, received sealed proposals on June 20 for dredging and rock excavation in Black Rock Channel, Buffalo, N. Y.

Dredging, Wilmington, N. C.—Sealed proposals were received by U. S. Engineer Office, Wilmington, N. C., on June 19, for dredging in Scuppernon River, North Carolina.

Jetty Repairs, Galveston, Tex.—Sealed proposals were received by U. S. Engineer Office, Galveston, on June 22, for repairing, building up and extending the West Jetty at Sabine Pass, Tex.

Stone, Chicago, Ill.—U. S. Engineer, 537 South Dearborn street, has awarded the contract for crushed stone or gravel in Calumet Harbor, to L. D. Smith Stone Company, Sturgeon Bay, Wis., \$9,660.

Contract Awarded, Wilmington, Del.—U. S. Engineer Office awarded the contract for dredging Tucker Creek, N. J., to Delaware Dredging Company, 139 South third street, Philadelphia, Pa., \$9,180.

Bids on Buoys, Tompkinsville, N. Y.—The Superintendent of Lighthouses, Third District, at Tompkinsville, Staten Island, received sealed proposals on June 18 for furnishing and delivering a total of nine buoys.

Steel Oil Barges, Cincinnati, O.—Sealed proposals were received on June 22, by U. S. Engineer Office, Cincinnati, for the construction and delivery of two 1,800-barrel steel oil barges, 100 feet by 30 feet by 6 feet.

Steel Hull, New York, N. Y.—Sealed proposals were received by U. S. Engineer, Room 710, Army Building, 39 Whitehall street, New York, on June 21, for constructing and delivering one steel hull for quarter boat.

Superstructure, Dunkirk, N. Y.—U. S. Engineer, Federal Building, Buffalo, awarded the contract for a stone superstructure on breakwater at Buffalo, to Central Dredging Company, Bangor Building, Cleveland, Ohio. \$58,860.

Sale of Condemned Material, Newport, R. I.—A sale of condemned material belonging to the United States Navy will be held at the Naval Torpedo Station, Newport, R. I., on July 3, at 11 A. M. (daylight saving time).

Stone, Wilmington, N. C.—Sealed proposals, in duplicate, were received at the office of the U. S. Engineer, Wilmington, N. C., on June 15, for furnishing and delivering stone, f. o. b. Wilmington, N. C. Proposal No. 1877.

Dredging, etc., Richmond, Cal.—Bids were received June 1, at the office of the U. S. Engineer, Custom House, San Francisco, for dredging 910,000 cubic yards and building 2,000 lineal feet of retaining wall in Richmond Harbor.

Steel Piling, Addison, Ky.—U. S. Engineer, P. O. Box 72, Louisville, awarded the contract for furnishing 435 tons of steel sheet piling, for Dam 45, Ohio River, Addison, f. o. b. Louisville, to Bethlehem Steel Company, Bethlehem, Pa. \$26,000.

Dredging, etc., Chicago, Ill.—U. S. Engineer, 537 South Dearborn street, awarded the contract for dredging and pier removal in Calumet Harbor and River, Illinois and Indiana, to Fitzsimmons & Connell Dredge & Dock Company, 10 South LaSalle street, \$70,614.

Dredging, New Orleans, La.—Grant, Smith & Company, Raceland, received the contract awarded by the U. S. Engineer, 329 Custom House, for dredging Intracoastal Waterway between Bayou Black and Bayou Terrebonne, 333,000 cubic yards, \$0.23 per cubic yard.

Sluice Gates, etc., Florence, Ala.—U. S. Engineer Office, Florence, Ala., received sealed proposals on June 23 for furnishing and delivering 13 sets of sluice valves, operating mechanism for the same, riveted steel pipe and other appurtenances for the sluice section of Wilson Dam.

Proposals for Iron Chain, Tompkinsville, N. Y.—The Superintendent of Lighthouses for the Third District at Tompkinsville, Staten Island, will receive sealed proposals until 2 P. M., on July 5, for iron stud link light vessel chain and iron open link buoy chain. Further information upon application.

Two Steel Oil Tanks, Memphis, Tenn.—Sealed proposals will be received by U. S. Engineer Office, Mississippi River Dredging District, Post Office Box 1017, Memphis, Tenn., for constructing, delivering and erecting two steel fuel oil storage tanks at U. S. Dredge Depot, until 9:30 A. M., July 19. Further information on application.

Dredging, Los Angeles, Cal.—The San Francisco Bridge Company, Nevada Bank Building, San Francisco, Cal., was awarded the contract for widening Los Angeles Inner Harbor entrance channel—Area 3, \$419,226; and F. C. Franks Construction Company, American National Bank Building, San Fran-

cisco—Areas 4, 5 and 6, \$337,953, by U. S. Engineer Office.

Dredging, New York, N. Y.—The contracts for dredging in New York and New Jersey Channels, Area 1 to Great Lakes Dredge Company, 17 State street, \$229,425; Area 4, to Morris & Cummings Dredging Company, 17 State street, \$226,152; Areas 5 and 6, to Taylor Dredging Company, foot of Communipaw avenue, Jersey City, N. J., \$330,534, have been awarded by U. S. Engineer, 2nd District, Army Building, New York.

Lumber, Louisville, Ky.—U. S. Engineer Office, P. O. Box 72, has awarded the following contracts: furnishing 100 pieces 3 and 4 by 10 inches by 30 feet rough oak; 125 pieces 12 by 12 inches by 12 feet oak; 120 pieces 2 and 6 by 12 inches by 14 feet oak, and 35,000 feet long leaf yellow pine, to Marsh & Truman Lumber Company, 332 South Michigan avenue, Chicago, \$3,368, and Hayden & Westcott Lumber Company, 80 East Jackson Boulevard, Chicago, \$1,606.

New Storage Yard, Florida.—It has been announced from Florida that historic Fort Norfolk, a show place preserved for a century, will be razed and turned into a storage yard for buoys by the lighthouse service unless some unforeseen powers step in to prevent. Application has been made by the lighthouse department to the U. S. Army District Engineer for permission to construct piers, warehouses and storage places for vessels and buoys on the section allotted to that service recently by the Government.

Anchorage Improvement, Norfolk, Va.—Enlargement and improvement of the anchorage grounds off Craney Island and Lambert's Point in the Norfolk harbor has been tentatively approved by the Chief of Army Engineers. Authority for survey and preparation of the project has been received by Major D. D. Pullen, U. S. Army district engineer here, from the Chief of Engineers, with instructions to proceed immediately with compilation of figures to show the costs, the amount of work to be done, and the results to be attained.

Earthwork, New Orleans, La.—U. S. Engineer, 4th District, Custom House, awarded the following contracts in connection with 1,907,100 cubic yards of earthwork in Atchafalaya and surrounding districts: to D. B. Hearin & Son, New Raymond Building, Baton Rouge, St. Cloud Levee, \$18,810; to O. O. Ogden, Roumain Building, Baton Rouge, Nina Levee, \$77,400; to Lafourche Basin Levee Board, Donaldsville, Live Oak Levee, \$20,700; to H. A. Schoenberger, Triumph, Ballay Levee, \$4,025; Lee Rice Levee, \$4,370; Crombie Levee, \$2,208, and Bicks Levee, \$3,910; to Lower Coast Construction Company, Ltd., 122 Chartres street, Bowden Levee, \$18,720.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

A Real Saving

THE Fuel Conservation Committee created by Mr. Joseph E. Sheedy, vice-president of the Emergency Fleet Corporation, has accomplished a real saving in the amount of fuel consumed on Government ships. In spite of the increase of ship-miles covered by Shipping Board vessels and the material advance in the price of oil, the monthly expenditure for fuel has been kept at a constant figure. It is significant that, during the life of the committee, practically every other operating cost has, due to the higher prices of material and labor, been materially increased. This gratifying showing is due apparently to advantageous fuel oil contracts and also in considerable measure to the work of the Fuel Conservation Committee.

Fuel is the largest direct operating cost and the logical place to make the greatest saving. With this in mind the fuel committee had estimates made of the number of miles every Government ship in operation ought to make on a ton of fuel. When these figures were furnished to the chief engineers there was an immediate improvement in efficiency for they were an incentive for every engineer to do his best. They gave him a mark to shoot at and they also gave him the knowledge that someone was taking an interest in his personal work. It is human nature for good men to do their best when they know that credit will be given honest efforts.

Of course there were cases where the efficiency obtained was not what it should be and in such instances a thorough investigation was made to determine the cause. A notable

case where a great improvement was accomplished was on the *America* where changes in the boilers effected very large savings.

In addition to this, the Fuel Committee organized a school for engineers through the courtesy of the Navy Department at the testing plant of the Philadelphia Navy Yard. Here an intensive five-day course in the art of burning oil has been carried on since November. It has been open to engineers of both Government and privately-owned ships. The greatest endorsement that can be given to this school is the fact that the graduates have spread the news of the benefits that they have derived from taking this course to such good effect that it has been necessary to double the number of the classes.

Economy is the ideal of all true engineers. The avoidance of waste is one of Secretary Hoover's pet hobbies. Getting the business is important, freight rates are important but it is also true that those who have made the greatest success in shipping are those who have paid the best attention to reducing costs. Those who like their work will do it efficiently.

Two More Fast Ships Needed

IT is very gratifying to note the interest that the general public has taken in the *Leviathan*. Her reconditioning into a premier ocean liner has been accomplished with such skill that every American ought to be proud of the work of the Newport News Shipbuilding and Dry Dock Company and, judging from the amount of newspaper publicity that has been given to this great ship, something resembling that pride which our ancestors took in shipping has been revived in the public at large.

But the *Leviathan* has not and will not have a fair chance to make a financial success unless and until two more ships capable of making at least twenty knots are built and placed on the berth with her. This fact is well known to our foreign competitors, especially those who are at present prepared and do furnish a weekly express service.

Passengers cannot be expected whether going or returning to wait three weeks for a particular ship and, as to the forwarders of express freight, who are given a weekly service by English vessels, it will be out of the question no matter how patriotic they may be to expect them to disrupt their business and interrupt the fast delivery of their products in order to favor the *Leviathan*.

It is unfortunate that the age of the *Agamemnon* and *Mt. Vernon* and the cost of reconditioning them are such that the Shipping Board has felt it necessary to condemn the project of returning them to service. Whether or not they would

make a financial return on their conversion cost, they would at least fill a gap until they could be replaced with new ships and they might, in this way, be the means of deciding the destiny of one of our two great American transatlantic steamship lines.

Our great fleet of freight ships cost us many times what the Shipping Board would be only too glad to accept for them now. We hear a lot about the cost of their construction, but we hear very little about what these ex-German liners saved us in transporting troops. We would have paid to the owners of the *Leviathan* alone, if she had been under foreign control, something like \$42,000,000 for the passage money of the soldiers that she carried.

In other words, the ex-German liners have a credit balance for actual services on the ledger which ought amply to justify the construction of two new vessels. Naval experts know the actual need for such ships under American control, which is decidedly more urgent since the Disarmament Conference, and shipping experts know that they are absolutely necessary as running mates for the *Leviathan*. We must and will get these ships and, when we do, we will be just as proud of them as we are of our premier ship today.

Marine Insurance Dull

MARINE underwriters are viewing the business let-down of the last few weeks with misgivings. They are wondering whether it is merely a seasonal reaction, or an ominous attestation of the commercial decline of which one hears so much these days. Beyond question, the prevailing scale of prices in the United States, due to high costs of production, puts Americans at a considerable disadvantage in the export of manufactured goods. Dull foreign trade means dull marine insurance. It is the general opinion that underwriters made no money during the first half of 1923. Losses have been heavy and premiums have scarcely equaled the volume for the corresponding period of last year. The summer months are bringing little relief. The likelihood of profit in 1923 is steadily growing more and more remote. It seems certain that our export of manufactured products will continue to decline in comparison with the export trade of other countries, and the more progress Europe makes in getting on her feet, the more competition will this country feel in her export trade of manufactured merchandise. The bright side of the apparent cloud lies in the reflection in our raw products' trade, such as copper, cotton, grains, etc., of future orders from abroad when European nations get more upon their feet and undertake an expansion of their business. This is the time for sound sense and the best brand of courage we can all command.

Writing the Rum-Runners

MARINE underwriters are frequently queried concerning the liability for damage to vessels and cargoes arising out of the activity of that class of bootleggers known as rum-runners. And not without reason. From time to time reports reach shore of collisions with mysterious craft and of damage done vagrant vessels and legitimate carriers alike; and the source of this injury is

clouded and obscure. Too often the rum-runner is in the offing and to blame for the disaster. What are the rights of all concerned in this case, so far as their insurance protection goes?

The legality of the venture is one of the implied warranties of marine insurance. This, naturally, precludes recovery under American policies for damage to vessels engaged in rum-running, or to their cargoes. Under the laws of misrepresentation and concealment, it would appear to be incumbent upon the party seeking insurance to make known to the insurer the character of the business in which the applicant is engaged. Damage to a vessel engaged in legal trade, due to collision with a smuggler, is, of course, recoverable under the American policy. However, there would not be much difficulty for an American to obtain insurance in Great Britain covering smuggling operations, because the United Kingdom does not recognize the laws of a foreign nation to the extent of permitting such laws to invalidate contracts made in Great Britain when the contract is within the British law. It would appear, therefore, that any protection desired in this form of activity must be sought outside the United States.

Deviation Charges

IT is not always clear to shippers why they should be charged extra for a deviation from the set route at sea.

They complain to their underwriters that they have not profited by such a change of course and ought not to have to pay on account of it. There is good and sufficient reason, just the same. When the insurer makes up his rate he takes into careful consideration every hazard involved in sailing from one given point to another, along an agreed course. The moment the voyage is altered and additional harbors are made there arise numerous hazards that he had not taken into account. No vessel can enter and leave a harbor without running increased risk of collision and stranding, not to mention perils involved in the opening of hatches for coaling or cargoing the vessel, one of the most dangerous of which is fire.

Illustrations abound in substantiation of this attitude of the underwriter. A short time ago a large Lamport & Holt liner went aground at Bermuda when entering the channel off Hamilton, and her position, for a time, threatened to prevent the entrance of a regular steamer of call. She was bound to New York from South America, and although the bill of lading may not have construed a stop at Bermuda as a deviation it most certainly was such by the terms of the insurance policy. Fortunately the steamer was floated in time to save the insurers a heavy loss, but it might easily have cost the New York insurance district thousands of dollars. The Pacific Coast, several months ago, supplied a still more dramatic illustration of the perils involved in deviations. The *Welsh Prince* went aground in an attempt to deviate for extra cargo at Portland, Ore., and became a total loss. The underwriters were called upon to foot the bill, which ran into a round million dollars. Is this not a hazard worth an additional rate? And the charge is trifling—only from five cents to seven and a half cents per hundred dollars. It can scarcely be considered exorbitant.

Leviathan Awakens America's Interest in Shipping

Race with Majestic Would Stimulate Favorable Public Opinion—Two More Ships Comparable in Speed Needed to Establish Weekly Service

By "Old Scotch"

TO the American marine public, torn with conflicting emotions as to our future and jaded with continuous depression in business the completion and official trials of the *Leviathan* came at a psychological time to stir up shipping sentiment as no other event has done in several years.

The attack of partisan journals on the so-called "joy ride at the tax-payer's expense" riveted public attention to this "Queen of the Seas" as nothing else could have done. Since the advent of the *Great Eastern*, over seventy-five years ago, no single ship has ever been so much in the public eye, not alone in this country but in every maritime country in the world. Chairman Lasker, professional advertising man as he is, could have devised no better means for putting this great ship on the map than the trial trip which he initiated, supervised and brought to such a successful ending. Threats of injunctions and Congressional investigations deterred him not, for he was assured by all experienced shipping men that he was pursuing a perfectly legitimate and necessary course. The small additional sum to feed the guests on board during the trial paled into insignificance in comparison with the financial returns which will accrue as a direct result of the wonderful amount of advertising resulting from the newspaper attacks.

What rival steamship line would not have pulled off a much more expensive trial, if they could have been reasonably sure of even one-half the gratuitous advertising which the *Leviathan's* trial received?

THE LEVIATHAN'S SPEED

The announced speed obtained meant just exactly what it stated, no more, no less. That it was made in the Gulf Stream, with possibly three or four knots favoring current, is known to all who are familiar with shipping. All the crack runs of rival ships, let it be noted, are given out on the eastbound trips, where the Gulf Stream is an advantage. Why have not rival ships given out record runs westbound? The answer is for the same reason as those obtaining for the *Leviathan's* run—advertising. The public at large little care for attendant circumstances. Americans for once out-advertised foreign competitors by taking advantage of a little more current than the other fellows.

RACE WITH THE MAJESTIC PROPOSED

As a really sporting proposition none of those "record runs" of rival greyhounds amount to anything in the minds of seafaring people. Conditions of wind, sea and currents vary so much at sea, that it is not alone impossible but inadvisable to consider seriously the record made by any ship which speeds alone on ocean lanes. Spasmodically we indulge in International yacht races, where all competitors are on an equal basis as to weather and tidal conditions. There, real class of vessel and skill of navigators are at stake. At his time the greatest sporting event on the ocean that the world has ever seen would be to put the *Leviathan* and the *Majestic*, for example, side by side off Ambrose Light, give them an even start and the first one to reach Daunt's Rock or Cherbourg Breakwater can well be proclaimed the better ship. Then all arguments about sea temperatures, favoring currents or weather conditions would be dispelled. It would be a battle royal between engineers and navigators of the United States and Great Britain. Needless to say every

available inch of passenger accommodations would be taken on both ships.

The ludicrous part of such a race would be the fact that America and England would be battling for transatlantic supremacy with German-built ships. Even so, they have both been overhauled and reconditioned by the best talent in England and America, and the test would be fairly indicative of the available skill in both countries, in shipyards and among sea-goers.

Such a race would attract the attention of every citizen in both countries no matter how remote they might be from the seaboard. All English speaking people go in for fair sports and, instead of engendering any ill-feeling between the two great Anglo-Saxon nations, the reverse would undoubtedly result.

The benefit to the American merchant marine would be incalculable. The farmers and cowboys of our great inland empire would no doubt be as much interested and excited over such an international contest as the people living along our seaboard. If perchance our pet ship should be whipped, it is dollars to doughnuts that we would go after the championship with renewed vigor, and the next contestant flying our flag would be a ship designed and built in our own yards, and manned by our own people throughout.

It is safe to say that the American merchant marine has already received more of an impetus from the great publicity attached to the *Leviathan* trials than it did from all the campaign of education which we launched during the consideration of the late-lamented shipping bill. All it needs now to put over the great idea of American ships is to stage a *Leviathan-Majestic* overseas race. From quoted expressions of British captains, they are willing to engage in such an encounter. Are we not just as good sportsmen, and have we ever before been unwilling to back up our own ships in any contest of this kind? Newspaper records with all the attendant bluffs get us nowhere. Let's be game!

PASSENGERS ENTHUSIASTIC OVER VESSEL'S PERFORMANCE

The fortunate guests who participated in the now famous trial of the *Leviathan* were as representative a body of Americans as have ever been gathered together in any ship under the American flag. Leading men in the shipping business, railroad presidents, great business men, prominent journalists, and well known citizens from all parts of the country mingled together and got a better idea of the possibilities of an American merchant marine than could be obtained in any manner ever devised. Their enthusiasm was unbounded, as is best evidenced by the spirit displayed in raising in a few moments a purse of six thousand dollars to be distributed among the engineering force, whom they readily saw were the portion of the crew to whom credit for the splendid performance was due. Incidentally, this is probably the first instance on record where favors and praise were bestowed on the right people for a creditable performance of a steamship.

A further evidence of the fine spirit developed, was the announcement of several very prominent business men who were on board, to the effect that hereafter their buyers, who make hundreds of trips annually to Europe, would be directed to patronize American ships exclusively. That development alone was worth more than the entire expenses of the trial trip. When we consider that over seventy-five per-

cent of all money spent in transporting persons and goods between the United States and Europe emanates from our own pockets, is it not time that we gave heed to keeping a fair proportion of this money at home?

THE LEVIATHAN GOES INTO SERVICE

The sailing of the *Leviathan* on Independence Day was witnessed by a crowd of over 15,000 people massed around her pier, and by countless thousands from the densely populated portions of the great city bordering on or in sight of the harbor. The weather conditions at the time may be, we trust, quite prophetic of the future of our shipping efforts. She started to back out from the wharf promptly at the appointed hour amid the din of steam whistles and the whirring of airplanes overhead, but the heavens broke loose with an inundation of rain which compelled every one to scatter for shelter. She started majestically down the harbor under dark, lowering clouds and an atmosphere through which it was most difficult to grope. Before reaching the open sea, the clouds had disappeared and the brilliant July sunshine made the spectacle of America's pride starting on her first voyage a marine spectacle long to be pleasantly remembered.

Although our merchant marine endeavors are now struggling with adverse conditions, who can or will say that these temporary clouds will not soon disappear, and that the warm sunshine of public approval and a determination to succeed will not eventuate in scattering the clouds of adversity which up to this time have tended to discourage us?

TWO MORE FAST SHIPS SHOULD BE BUILT

It will be difficult and, in fact, impossible to maintain adequate service under the American flag with but one first-class vessel like the *Leviathan*. Let us all get behind the Shipping Board's announced policy of asking Congress to appropriate money to construct two more comparable ships for the North Atlantic trade, so that Americans can travel to distant lands under our own flag. The Board has the

money and all that Congress needs do is to make it available for this new construction. Our yards are at present capable of turning out two ships which will lead the world for comfort, size and speed. In a few years under the present outlook, we will not have the necessary facilities and talent for building such ships.

Our national pride and the dictates of self defense and commonsense all demand that we should build two such ships. A trio of such fast and commodious vessels are absolute essentials in our program of national defense, and, for that purpose alone, the expenditure of the necessary money would be more than justifiable. With the proper national spirit behind them, such as has already been started by the advent of the *Leviathan*, there is but little question that they would be a good instrument financially, either in public or private hands.

Let us all unite in the toast "Hail *Leviathan* Redivivus, and may good luck attend you everywhere!"

AUXILIARY SAILING HOUSEBOAT LAUNCHED.—Mr. Fred S. Fish's auxiliary sailing houseboat *Moby Dick*, designed by Henry J. Gielow, Inc., New York, which was launched at the Harlan Plant of the Bethlehem Shipbuilding Corporation, Ltd., Wilmington, Del., on June 30 is an interesting example of a high grade craft of a type especially designed and adapted for shallow draft cruising in localities such as the Florida waters. It is the second of the same type to be launched this season at the Harlan Plant, the other being Mr. Keith Spalding's auxiliary schooner yacht *Goodwill*. The auxiliary power is furnished by a Diesel engine and ample accommodations have been provided for guests and crew, quarters being available for ten of the former and eight of the latter. The vessel is 120 feet long overall, 24 feet 8 inches molded beam, 10 feet 8 7/16 inches molded depth and will have a draft of 6 feet 10 inches.

S. S. Albert Ballin Nearing Completion at Blohm and Voss Shipyard, Hamburg, Germany

The Twin Screw Turbine Steamer Albert Ballin

New Hamburg-American Liner Fitted With Stability
Bulges and Anti-Rolling Tanks Placed on New York Berth

By Dr. Ing. E. Foerster

AFTER the great war, through which Germany lost practically its entire mercantile fleet, she has endeavored to rebuild at least those units which would enable the reorganization of some few main passenger lines crossing the North and South Atlantics.

With respect to the River Plate service, the most remarkable vessel now in that trade (the 21,000-ton triple screw liner *Cap Polonio*) was rebought by their pre-war German owners, after she had been delivered to the Allies according to the treaty of Versailles. This steamer, therefore, is representing the German passenger traffic in that trade together with some smaller liners of the same company and of the Hamburg-American Line.

On the North Atlantic practically all vessels of value were transferred, by the treaty, to British and American owners, the most significant ones being the *Vaterland*

(*Leviathan*) and the *Bismarck* (*Majestic*) both having been built by Blohm & Voss for the Hamburg-American Line.

With respect to passenger service, the Hamburg-American Line has reconditioned the former express liner *Deutschland* as a 17-knot freight and passenger steamer, and it has also built the *Thuringia* and *Westfalia*, all running in a special fixed agreement with the United American Lines. This latter progressive shipping concern bought from Holland the two formerly German River Plate liners *Resolute* and *Reliance* which in 1915 had been sold to the Royal Dutch Lloyd by the Hamburg-American Line. With these and other vessels the United American Lines and the Hamburg-American Line are running a regular service between the United States and Europe, the German partner aiming, however, at an improved representation in this combine, more in keeping with its traditions. The foregoing are, therefore,

View of Hull During Erection

the conditions which led to the building of the new Hamburg-American liner *Albert Ballin*.

One of the most striking novelties in this new vessel is the adaption of stabilizing bulges in the waterline, a proposal of the writer, who first recommended this method of local treatment of the question of stability" for River Plate steamers, in order to compensate by automatically increasing the stability of form for the loss of stability during the voyage, caused by the consumption of coal, oil, fuel, feed and fresh water, the maximum beam of the bulges, in this case, being in the "waterline of arrival."

In the case of the *Albert Ballin*, this principle has been adopted in order to save beam, meaning, that the beam necessary for the accommodations, was less than the beam which was necessary for stability. The latter was obtained on the principle of local bulges while the vessel's main beam (clas-

Performance Curves Based on Model Research Work

sification beam) remained on the practical basis of the lower figure. The *Cap Polonio* herself and a good deal of model tank research work in connection with the design of the *Albert Ballin* has proved the physical phenomenon, that the resistance of a given ship is, in higher speeds, diminished by adding bulges—and only very slightly, or practically not at all increased at lower speeds.

In combination with these bulges the new system of Dr. Frahm's anti-rolling tanks is adopted—a part of the bulges being used for this purpose and therefore communicating with the sea by openings in the outer hull.

The design of the superstructure is influenced by the merits of the bulges, showing a relatively high development especially of the bridge decks.

The *Albert Ballin* has been built by Blohm and Voss to the highest class of the Germanischer Lloyd of best mild

Siemens Martin steel, and conforms to all the rules prescribed by the American, British and German laws for this class and type of vessels, carrying passengers of three classes including emigrants.

With respect to safety appliances, including bulkheads and boats, the vessel is built and equipped according to the rules and recommendations laid down as a result of the *Titanic* conference for the protection of human life at sea.

PRINCIPAL DIMENSIONS

Length over all	627 feet 1 5/8 inches
Length between perpendiculars	599 feet 10 15/16 inches
Beam over inner frames	72 feet 9 inches
Beam over frames of bulges	78 feet 8 5/8 inches
Depth molded to first deck	55 feet 6 inches
Maximum draft	32 feet 7 13/16 inches
Carrying capacity, deadweight	12,796 Eng. Tons
Engine power	13,000 I. H. P.
Designed average speed	16 knots

The double bottom, representing a space of 2,300 tons, is used for fresh feed and ballast water in the usual way and for only 600 tons of spare oil fuel, the latter being principally carried in deep tanks above the tank top.

Outside of the double bottom feed and fresh water tanks of 1,000 tons capacity are provided.

The bunkers for oil fuel were carefully designed to pre-

vent leakages by deformation, caused by the bending stresses imposed by the waves. They have a net capacity for 2,730 tons of oil.

The cargo space contains 449,975 cubic feet measured to the lower edge of beams, the inner edge of frames and the tank top ceiling. In this figure, the refrigerated spaces of 3,038 cubic feet and miscellaneous spaces for provisions, paint, etc., of 3,815 cubic feet are not included. The plans show the general distribution of the space.

PASSENGER ACCOMMODATIONS

Amidships the vessel is arranged for the accommodation of the first class passengers. The second and third classes are distributed in the ends of the vessel as shown on the plans.

The total number of passengers that can be accommodated is as follows: First class, 127 cabins with 215 normal berths, 36 sofa-berths, 23 spare berths; second class, 103 cabins with 216 normal berths, 124 sofa-berths; third class, 186 cabins with 645 normal berths, 315 berths in compartments.

The first class has a dining saloon with 238 seats, a hall with 64 seats, ladies' saloon with 29 seats, smoking saloon with 100 seats, grill room with 36 seats, children's playroom with 22 seats, two deck-verandahs with 98 seats.

S. S. Albert Ballin: Midship Section

The second class has a dining saloon with 214 seats, a hall with 65 seats, smoking saloon with 72 seats, ladies' saloon with 76 seats and a deck-verandah.

The third class has a dining saloon with 345 seats, smoking saloon with 70 seats and ladies' saloon with 70 seats.

STEERING AND NAVIGATING APPLIANCES

The partly balanced rudder has been designed as a one plate rudder supported by welded arms. The rudder quadrant is installed on G deck. The steering engine is electrically driven. Two equal units are provided, one of them performing the service, the other being in reserve.

The Anschütz gyroscope compass combined with the self-steerer has been installed, enabling the vessel to be steered on a given course by the compass without a helmsman. This new principle, one of the most sensational inventions in shipping, is based upon the automatic work of a small motor in the compass box, which is controlled by the compass—this latter making the contacts for the working of the motor in

the one or the other direction. This motor is connected to the axis of the hand wheel of the telemotor by a Gall chain. The vessel has powerful submarine signalling and wireless installations, whose power is secured by an emergency motor generator in case of damage to the main engine or boiler plant.

There are four vertical steel masts and seven hatches, worked by twenty-one 5-ton Mannesmann-derricks and twenty-one steam winches. The provision hatches are worked by electric winches.

APPLIANCES FOR SAFETY AND LIFE SAVING

The vessel has 13 watertight bulkheads, which have no interruption whatever from the tank top up to the bulkhead deck.

The double bottom is raised at the sides in order better to cover the bilges.

The necessary openings in the bulkheads in the range of the engine and boiler plant are worked by an elaborate

Details of Reduction Gear

Sections Through One of the Propelling Units

Arrangement of Port Set of Four Ahead and Two Astern Turbines. Starboard Side Similar

hydraulic-pneumatic system developed and executed by the Atlas Works.

A further remarkable safety feature is the hydraulic-pneumatic system for closing the main scuppers after a collision, as these come below the water level. The illustration of this arrangement shows the principle of this important addition to safety, which excludes any water that may run into the vessel through scuppers below the bulkhead deck.

The number and size of lifeboats have been adjusted to the maximum number of passengers and crew on board.

All boats are placed under Welin quadrant davits. There are 28 normal lifeboats, diagonally built of oak, two of them being motorboats.

THE MAIN ENGINES

The main engines are two turbine plants of equal size, independent of each other but symmetrically arranged. Each set consists of four ahead turbines, and two astern turbines, driving one propeller by means of a single reduction gear through one large wheel gearing with two small pinions. The ahead turbine sets are composed of four cylinders. The pinion placed amidship is set in motion at its aft end by

New System Installed for Preventing Water Coming in Through Toilets and Washrooms In Case Vessel Sinks to Deeper Draft After Collision

Shaft Strut

the high pressure turbine, H.D.T. and at its forward end by the first intermediate pressure turbine M.D.I.T. The pinion next to the ship side, at its fore end by the second intermediate pressure turbine M.D.II.T. and at its aft end by the low pressure turbine N.D.T.

The principal advantage of this arrangement consists in subjecting the pinion to equal torsional strain from either side, to prevent a twisting inside the length of the pinion and to warrant an equal pressure on the tooth face. Further, this arrangement of the turbines avoids axial-thrust and balance-pistons inside the turbines. Therefore no thrust

parts, the second medium pressure turbine M.D.II.T. and the low pressure turbine N.D.T. are of pure reaction type.

The total power of the two turbine sets is 12,000 effective horsepower at about 2,100 revolutions. The astern turbines develop two-thirds of this amount, corresponding to the lower efficiency of the propeller blades.

Running astern, the inner pinion is driven by the high-pressure astern turbine H.D.R.T., the outer pinion by the low pressure astern turbine N.D.R.T., placed at the aft end of the pinion shafts. Both astern turbines are in the same casings as the corresponding ahead turbines. To avoid axial thrust of the astern turbines, they are designed as pure action-wheels with two rows of blades.

The two pinions of equal size engage with the large wheel, transferring the power to the propeller by the tunnel shafting. The propeller thrust is taken up by Michell thrust blocks, fastened to strong frames and foundations. The thrust block consists of a single thrust ring on the thrust shaft and the movable pads, 10 for going ahead and 10 for astern, each pad being adjustable by a separate set screw.

PROPELLERS

The two built-up propellers of 17 feet $0\frac{3}{4}$ -inch diameter and 17 feet $0\frac{3}{4}$ -inch pitch are composed of four bronze blades and cast iron bosses fitted with steel junk-rings. The two stern tubes are lined in the usual manner with lignum vitæ bushes.

The shafting is supported by 16 bearings, automatically lubricated by an oil circulating system. A thorough and copious supply of lubricating oil is essential for good working of the turbines. One duplex steam pump brings the oil up through a strainer to an elevated tank. From there it is distributed to all oil supplies, and flows back into a tank in the double bottom. Therefore all turbine, gear and thrust block bearings are supplied with oil of constant and uniform pressure. The gear's teeth get the oil over the whole width by distributing jets. The flow of oil and its temperature are under permanent control. To warrant sufficient lubrication of the whole plant before starting, an automatic valve is provided to shut off the main steam pipe, only allowing the steam to pass, when full oil pressure has been reached. It is designed as a double beat valve to be closed by a spring and counter-balanced by a piston, lifted by the pressure in the oil supply pipe. Should this pressure be diminished by any reason, the spring shuts the valve, cutting off the steam from the turbine.

In a similar way an explosion of the turbine-wheels, caused by a broken pinion shaft, is prevented by an emergency governor, placed at the end of each turbine shaft and set to act at a certain number of revolutions.

The ends of the turbines are made steam and air tight by labyrinth packings, consisting of solid dummy rings of soft metal, fastened in the stuffing box gland and the turbine spindle.

Running the plant ahead or astern, the stuffing boxes must be tight against pressures higher or lower than the atmosphere. Thus, in the first case, the escaping steam is led to the condenser by a suction pipe, while in case of vacuum, throttled steam may enter the stuffing box, preventing air leakage to the turbine.

The whole turbine set is controlled by two hand wheels, arranged on one table near the maneuvering platform together with revolution counters and manometers.

Special lifting arrangements, consisting of trolleys and pulley blocks are provided, affording an easy and accurate means of lifting and dismounting of casings and drums when required.

In order to obtain the shortest possible piping leads, the pumps and auxiliaries for engine and ship's service are placed together in groups. There are seven groups of machinery:

Steering Gear

bearings are provided, as the gearing itself, being right-handed and left-handed, fixes the position of the entire shaft.

The division of the turbine in four stages affords a very high steam efficiency, in spite of the relatively slow running turbines. Therefore a single reduction gear of 1:20 is sufficient to bring down the revolutions of the propeller to 110 per minute. By this system of gearing the difficult problem of combining turbine plant of high economy and small weight with an efficient propeller of low peripheral velocity has been solved.

By dividing the turbine, the heat stresses are reduced to a minimum, allowing tightness of flanges, dummy-rings and stuffing-boxes, which are of extraordinary small size, compared with the power developed. Better reliability and an easy overhaul of the plant are further advantages obtained. The high pressure turbine H.D.T. and the first medium pressure turbine M.D.I.T. consists of action and reaction

1. Condensing plant under the condensers at the aft engine room bulkhead.
2. Boiler feed plant at the forward engine room bulkhead between main engine plant and boiler room.
3. Pumps and apparatus for ship's service on either side of the engine room.
4. Refrigerating plant at the forward end of the tunnel next to the refrigerating rooms.
5. Appliances for fuel oil service at the forward boiler room bulkhead.
6. Electrical plant above the condensers.
7. Tanks and distribution boxes and branches in the engine room hatch and dummy funnel.

CONDENSERS

The aft condensers of pear-shaped section with a cooling surface of 6,458 square feet each, are placed athwartships, supported by the aft bulkhead of the engine room. The condenser tubes are of brass with an external diameter of $\frac{3}{4}$ inch and a thickness of 0.059 inch, the upper rows having a thickness of 0.079 inch.

Two circulating pumps with a capacity of 2,400 tons per hour at 250 revolutions per minute get their water from either side. The sea valves are fitted to the ship side close to the pumps, the cooling water pipes, therefore, are extremely short and handy. The cooling water is discharged above the condensers so that they will always be filled with water.

The air and condensate pumps are put underneath the condensers, in order to have short connecting piping.

Instead of the usual piston pumps for drawing off both air and water, the condensing plant is fitted with steam jet air pumps and centrifugal condensate pumps. This kind of condenser auxiliaries began to replace the piston pumps on board turbine ships during the past few years on account of the excellent results obtainable from steam jet air pumps on shore. On board of all ships, fitted with such pumps, all due expectations have been realized.

The steam jet air pumps are of the two stage type in combination with an intermediate condenser for condensing the working steam of the first stage, the second stage having only to draw off pure air. The exhaust steam of the second stage is condensed by a similar surface condenser. The condensate of the main condenser acts in both as cooling water, absorbing the latent heat of all the live steam. Only this new construction makes the system reliable and economical.

For each of the two condensers, there is installed a steam jet air pump having a steam consumption of 1,367 pounds per hour and, as spare, with a second one of 683.5 pounds per hour. Both pumps are fastened upon the intermediate condenser, and designed for a normal working pressure of 118 pounds per square inch, the large pump being able to draw off 103.6 pounds of air at 95 percent vacuum.

To allow sufficient low suction, a vertical design of centrifugal condensate pump was decided upon. The shaft is driven by a steam turbine, designed as an action turbine with two velocity stages. The rotor is fastened at the upper end of the shaft and the impeller of the centrifugal pump at the lower end. Both wheels are of the overhung type.

PUMP DATA

Capacity	64.4 tons per hour
Manometric head (including vacuum head)	75.5 feet
Revolutions per minute	250
Power absorbed	11 horsepower

TURBINES

Normal power	13 horsepower
Steam pressure	220.5 pounds per square inch
Temperature of steam	432 degrees F.
Back pressure	29.4 pounds per square inch

The condensate out of the main condensers is pumped into an elevated hot well fixed to the forward engine room bulk-

head. From there, the feed water flows down to the feed pumps.

FEED PUMPS

Two simplex pumps, constructed by Georg Niemeyer, Harburg-Elbe, and two turbine centrifugal pumps, by the A. E. G., Berlin, feed the boilers. To aid the suction to the centrifugal pumps, the feed water tank has been elevated. The shaft of the pump is supported by two oil ring bearings, the rotor of the turbine being fixed to the middle and the impeller on one end. The turbine casing and bearings are horizontally divided, giving easy access to the inner parts of the turbine and the bearings, after lifting the cylinder cover and bearing caps. The pedestals and lower parts of the casing are a solid casting, one end being flanged for fastening the pumps. The steam chest, with the by-pass valves, the nozzle block and the distributor are fastened to the turbine cover. The inlet connecting branch supports, the stop and throttle valve are combined in one casing. The first, being formed as safety shut off valve, may be closed by hand or governor. It is automatically put in action to prevent racing of the turbine when a pipe fracture occurs. The throttle valve, being controlled by regulating apparatus,

Steam Injector Pump for Auxiliary Condenser

regulates the output of the pump, corresponding to the necessary amount of water, by adapting the steam admission of the turbine to the pump's want of power. The suction pipe is flanged to an axial inlet connecting branch, while the tangential pressure connecting branch joins horizontally.

The turbine is constructed as a one stage action turbine, partially admissioned, with three velocity stages. It is fitted with nozzles, to be run as a non-condensing engine.

A feed water heater of 753 square feet heating surface raises the feed water temperature to 248 degrees Fahrenheit.

The auxiliary condensing plant is installed at the port side of the engine room. It consists of one circular shaped auxiliary condenser with 753 square feet of condensing surface, one simplex air pump and one circulating pump. The auxiliary condenser takes up the exhaust steam of the auxiliary engine, turbo generator, refrigerating machinery, winches, heating piping and galley apparatus. Several pumps for ship's service are installed at the same side of engine room.

EVAPORATOR

At the starboard side of the engine room, there is arranged a vacuum exhaust steam evaporator.

Other auxiliaries in the engine room comprise pumps and apparatus for oil service of the main turbines, for double bottom and bilge service, water supply to passenger accommodation and galleys.

The refrigerating plant is placed aft of the engine room

Arrangement of Oil Burners

and is composed of one double acting engine with a capacity of 200,000 kilogram-calories and a small one of 17,500, together with the necessary apparatus. Besides there are installed pumps and tanks for operating the watertight doors, an interesting innovation being the vertical differential pressure pump. Further aft, two sand filters and two simplex drinking water pumps are arranged.

BOILER PLANT

The boiler plant consists of four single ended and four double ended Scotch boilers, fitted with steam superheaters,

the heating surface of the boilers amounting to 32,300 square feet. The single ended boiler has three and the double ended boiler, six furnaces of the Morison type, of about 3 feet 9 $\frac{3}{8}$ inches diameter, the working pressure being 213 pounds per square inch. The superheaters, constructed as return pipes inside the smoke tubes, raise the steam temperature up to 662 degrees Fahrenheit. The uptakes of all boilers join together in one funnel.

Two fans, driven by steam engines and producing compressed air for the furnaces, are put above the bulkhead between the engine and boiler rooms, in order to draw off the hot air rising from valves, pipings and fittings on the bulkhead.

It may be mentioned that small steam turbines, to be started from the working passage, are provided for shutting off the boiler main stop valves in case of necessity.

The boilers are fitted with the Blohm & Voss oil burning system which affords economical and efficient combustion. The oil, atomized by the burners, goes into the furnace in the form of a conical spray. The burners are surrounded by a double ring of guide blades, in order to direct the air, coming from the blowing engine, tangentially into the oil cone, thus causing a quick rotating flame. By this method a perfect mixing of oxygen and oil particles is performed, producing ideal combustion, and at the same time preventing local superheating of the furnace.

The air blades are of different design, the first ring guiding the air to the outer zone of the oil cone, the second ring of blades being directed nearer to the cone's axis. Thus, even at the highest burner capacity of 529 pounds per hour, no unburnt oil particles will hit the furnace wall. Therefore, settling of coke inside the furnace, the principal drawback of many oil burning systems, is prevented, the boiler plant being adapted for the most trying conditions of oil quality and service.

In order to give an easy access to the furnaces and furnace chambers, it is possible to swing out the inner blade ring.

To prevent unequal heating or cooling of the furnace, inside brickwork is avoided everywhere.

OIL BUNKERING SYSTEM

To take oil on board, two filling stations with filters and control tanks have been installed. The oil flows from there

Section Through Oil Burning Furnace

Main Pump for Hydraulically Closing Doors in Watertight Bulkheads

into the oil tanks through the filling and circulating pipe, preventing excessive pressure or high temperature in the oil tanks caused by filling. A special reserve tank takes up the surplus of oil by means of an overflow pipe. Moreover this overflow pipe is used as a vent pipe, having its outlet at the top of the fore funnel. A simplex steam pump transfers the oil from the tanks on one side of the ship to those

Main Pump for the Fuel Oil

on the other side or to the settling tanks, which separate water from the oil before using it. From there the oil is drawn off by an oil feed pump through an interchangeable duplex suction strainer and then forced into the burner supply pipe through a steam oil heater and an interchangeable duplex discharge strainer. By the heaters, the oil temperature is raised up to 248 degrees Fahrenheit. The burner supply valve by-passes the surplus oil to the settling tanks or to the suction pipe. The piping is fitted with air receiver, to ensure uniform pressure in the burner tips. A second complete oil feed plant is installed as a stand-by.

The amount of oil in the bunkers, settling tanks and over-

Oil Fuel Pump

Lubricating Oil Pump

flow tanks is indicated by means of pneumercators, which show the height of the oil levels.

All pumps and apparatus for oil burning service are arranged together at the fore boiler room bulkhead, to ensure simple and easy handling.

SERVICE AND FIRE PUMPS

The deck wash and fire extinguishing pipes starting from the main distributing branch in the engine room are led as main lines inside the engine and boiler room hatches and from there in two lines through the whole ship.

Cold sea water is provided for all baths, toilets, lavatories and galley, cold fresh water for all first class wash stands, galleys, suite-de-luxe and hospital baths, and on each deck at many tapping points. Warm sea and fresh water is provided through circulating piping, having heaters in the engine room and tanks in the dummy-funnel. Warm sea water is led to all baths, toilets and lavatories, while warm fresh water is only provided for the wash stands of the suites-de-luxe, first class barber shop, and hospital baths.

The main stop valves for sea and fresh water piping are placed in the engine room hatch; there each deck may be shut off separately.

VENTILATION

First class inside cabins, all second class cabins, as well as crew accommodations get artificial ventilation, while in the third class, the gangways only are ventilated. Suction of air is fitted from all baths and lavatories. Artificial ventilation is also provided for galleys, provision and refrigerating rooms. Saloons, dining and smoking rooms receive an ample supply of fresh air; 21 discharge and 19 suction fans with electrical motors are arranged on deck or in special rooms. Five more fresh air fans are installed for ventilating the engine rooms and both stokeholes.

HEATING

Live steam, taken from the auxiliary steam piping, is throttled down to 59 pounds per square inch pressure for deck heating, and to 44 pounds per square inch for galley purposes.

Two main steam distributing branches are fastened in the engine room hatch, the heating branch being divided in such a way as to allow separate control of heating for crew and passenger rooms and baths. The different positions in each deck are under separate control by special distributing branches, the exhaust piping being similarly constructed. To prevent water hammering, the exhaust steam piping is inclined towards the engine room.

Copper coils, to be shut off at the steam inlet and outlet, are used as heaters in the cabins, supply and exhaust pipes being laid behind paneling.

THE ELECTRICAL EQUIPMENT

The main generating equipment consists of three 220 kilowatt turbine driven generators and the emergency equipment of two 25 kilowatt oil motor driven generators. All generators are direct current with a terminal voltage of 115 volts. The three turbine driven generators are connected in parallel to the same bus bars, but generally only two are running and the third is principally for stand-by service.

On the ship nearly all auxiliary machines are driven by electric motors. Consequently it was necessary to insure non-failure of bus bar voltage under all circumstances. This was taken care of by the patent of Carl Meyer, which properly equalizes the load even though one of the generators should unexpectedly cease to function.

The switchboard in the emergency dynamo room may be fed as well by the turbine driven generator as by the oil motor driven emergency generators. On this switchboard are the circuits for the emergency lighting plant, for the emergency

equipment of the steering engine, the wireless plant, the position lights, the Anschütz gyrocompass, the alarm and telegraph installation. The two oil motor driven generators also run in parallel, but on a separate system from that of the turbine driven generators.

AUXILIARY POWER PLANT

The power plant consists of 104 motors having a combined horsepower of 900. Electric drive is used for the steering engine, the warping winches, the elevators, the ventilators, the pumps, the cargo winches and kitchen machinery. Only the specially built type of the electric driven steering gear will be described.

The rudder quadrant is driven by means of a self-locking worm by two steering engines, equal in size and fully independent, each driven by a separate electric motor. One of these two driving mechanisms is for stand-by service and the driving wheel of this machinery is not engaging with the toothed worm gear. In the steering engine room one change-over switch is provided for each of the two steering engines to connect them either with the steering wheel on the bridge or with the emergency steering wheel. In the first case the steering engine is driven by one motor generator by the Leonard system and in the second case by one normal tension switch with constant voltage and half slowed down speed. For working with the Leonard system two motor generators are arranged in the main generating station, one for stand-by service. Each of the two motor generators is connected with a steering lever on the bridge. The rudder motor turns back this steering lever to its starting point by electric synchronous transmission which is constructed according to our own patent system and replaces the old fashioned mechanical transmission.

ELECTRIC FANS

The electric ventilating system is worth mentioning. The fan motors are started from one central switchboard in the main generating station by electric transmission turning the levers of the self-acting starters beside the motors. The speed of the fans is controlled from the same central switchboard.

ELECTRIC HEATING

Electric heating in addition to steam is used for the first class passenger cabins. This circuit is separated from the electric heating, of several heating plates in the saloons, of the hot water boilers in the pantry and of baking ovens and toasters.

LIGHTING

The lighting plant is divided in all-day burning lamps, in switchable lamps and emergency lighting. The current for the distributing stations of the all-day burning and switchable lamps is conducted from the main switchboard by separate cables. The distributing stations for the emergency lighting are connected with the emergency switchboard, which is direct connected with the main switchboard but, if this connection is switched off, it gets the current from the emergency generators. The 600 lamps of the emergency lighting are distributed all over the ship, including all lamps of the engine and boiler rooms.

LLOYD'S SHIPBUILDING REPORT.—The decline in world shipbuilding has now reached new low levels, both in respect to orders placed and work actually under way, says a statement just issued by Lloyd's Register of Shipping, giving returns for the quarter ended June 30. While a gain was shown in the first quarter of this year in the work on which construction was progressing that gain was eliminated in the quarter just ended, and all the shipyards of the world have only about two and a half millions gross tons of orders.

Steamship America Becomes Largest Cabin Ship Afloat

Extensive Alterations at New York Navy Yard Convert Vessel Into High Grade One Cabin and Third Class Passenger and Cargo Liner

ON June 2 the steamship *America* of the United States Lines sailed from New York for Plymouth-Cherbourg and Bremen on her first voyage as a one cabin and third class passenger vessel, after being extensively reconditioned at the New York navy yard. The principal alterations were carried out to take care of the increasing demand for good accommodations and service at more moderate rates than those existing for very large first class liners.

This vessel, formerly the *Amerika* of the Hamburg-American Line, built by Harland and Wolff, Belfast, in 1905, was among those vessels seized by the Government after the declaration of war in 1917. After her war service as a troop transport the *America* was placed temporarily in the transatlantic service with accommodations for first, second and third class passengers. The vessel was withdrawn from that service at the first opportunity for general reconditioning and extensive alterations to be converted into a high grade one cabin and third class passenger and cargo vessel, with the result that the *America* is the largest and one of the best cabin ships in service, fully in keeping with the significance of her name.

The reconditioning of the vessel, which was accomplished in 78 consecutive days by the New York navy yard, comprised a complete overhaul of her machinery, the dry docking of the vessel for scraping and painting the hull and extensive changes in the passenger accommodations, some of the most striking of which are described in the following.

MAIN SOCIAL HALL

On "A" deck the space formerly occupied by the first class dining room has been converted to the main social room paneled with contrasting hardwoods in natural finish, chestnut, sycamore and mahogany on walls with chased bronze trimmings applied. The ceilings were painted and decorated in harmonious tints. Casement windows and a skylight covered with ornamental glass and mirrors give sufficient light in daytime, while numerous ceiling lights and wall brackets provide artificial illumination.

A teakwood parquet dancing floor covers about one-third the area of the room, flanked by rich carpet and rugs while rugs are also used on the dancing floor when it is not in use.

Comfortable furniture of mahogany and tapestry of a design to suit the period of the wall decorations has been provided and the effect, while simple, is harmonious and rich.

On this deck twelve new outside staterooms have been built in the space formerly occupied by the auxiliary dining room and men's and women's toilets were built along the centerline in order to increase the passenger accommodations.

Each of the new staterooms is equipped with one four posted bedstead with pullman berth over, one sofa berth with upper berth over, all of mahogany, two wardrobes and two lavatories with running water. The pullman berth, when lowered, rests upon the posts of the bedstead and hence is not dependent upon bulkhead fittings for support when occupied. The sofa berth, when unoccupied, may be made up as a comfortable settee. The whole arrangement has such flexibility that the rooms may be made to comfortably accommodate either one, two, three or four persons. The settees are upholstered to harmonize with the color scheme in these staterooms.

CABIN SMOKING ROOM

One of the features of this ship is the cabin smoking room which extends for two deck heights. The illustrations give an idea of the splendid general appearance of this room, the upper deck being, as shown, in the form of a broad gallery with an open space in the center, allowing light from the skylight overhead to illuminate both decks. This room is representative of a hunting room of an Elizabethan manor house, with solid oak hand carved woodwork.

CABIN DINING ROOM

The space on "D" deck now occupied by the cabin dining room was formerly used as a second class dining room and social hall. This space was completely dismantled and fitted up and equipped as the cabin dining room to accommodate 328 passengers in one sitting. It is about 90 feet long, extends the full width of the vessel, and is located just forward of the main galleys and pantries thereby insuring good service.

The design of the woodwork is Colonial, finished in soft colors. Casement windows conceal the airports without excluding the light. A well has been opened over the center of the room, giving a sense of height and space. Tables for two, four and six persons are used throughout. Handsome electric light fixtures adorn the ceiling and walls and silver candelabra table lamps have been provided for each table. The deck is covered with rubber tile of marble pattern. A

Interior Views S. S. America: (1) Upper Smoking Room, (2) Library, (3) Corner of Ladies' Lounge, (4) Fireplace in Smoking Room, (5) Grand Staircase, (6) Lower Smoking Room, (7) Stairway Leading from Lower to Upper Smoking Room

Interior Views of S. S. America: (8) Children's Playroom, (9) Ladies' Lounge, (10) Dining Room, (11) Social Hall, (12) Dancing in the Social Hall, (13) One of the Roomy Staterooms

glass partition at the after end separates the stair lobby from the dining room.

The dining room was designed by Messrs. Walker and Gillette, architects, New York City, who also selected the electric light fixtures and hangings and furnished the color scheme. Messrs. J. C. Knipp and Sons, Baltimore, Md., were the contractors for the woodwork and finish of this room.

GALLEYS AND PANTRIES

After a careful study the galleys and pantries were rearranged and refitted in accordance with the best marine practice and are now so arranged as to give excellent service.

The cabin galleys and pantries are directly aft of the cabin dining room. The third class galleys and pantries have been rearranged and are now adjacent to the cabin galleys and pantries and the third class dining room is directly aft of the third class galleys and pantries.

Particular care has been taken to exclude all woodwork, as far as is practicable, from the galleys and pantries. This detail has been carried out even to table tops and shelving which in most cases are metal.

The third class dining room has been enlarged, altered and refurnished to bring this room strictly up to the United States Line standards and now accommodates 360 passengers in one sitting. The old benches have been removed and comfortable swivel chairs installed.

SUPERSTRUCTURE STIFFENED

Approximately 60 tons of steel were worked into the forward portion of the vessel's superstructure in the form of new deck plating, house plating, doublings, fashion plates, all with a view to providing additional stiffening to the superstructure where it was found to be required.

The ventilation systems, both mechanical and natural, have been thoroughly modernized and the air changes are in accord with the very best marine practice. Twelve new mechanical ventilation sets were installed and the old sets over-

hauled and extended. The natural ventilators were thoroughly overhauled.

NEW WIRING INSTALLED

The ship was rewired throughout with lead and armored cable. New electric lighting fixtures were fitted and wired with the loop system with lights in staterooms controlled by three and four way switches. A new telephone system, of the Magnavox type, was installed. A new annunciator system, of the Cory reset type, was installed with a reset button at each stateroom door. The switchboard was remodeled. Reversite circuit breakers were installed on each generator feed. Power bus bars were separated from lighting bus bars. The speed of the dynamos was reduced 45 revolutions per minute and the field coils of each generator lowered one-eighth inch to compensate for the slower speed.

All main subdivision bulkheads have been thoroughly gone over and made absolutely watertight. Wherever practicable, watertight doors in main subdivision bulkheads have been permanently closed. The main watertight doors are operated from the bridge by the Stone-Lloyd system.

All piping systems were reconditioned and extended to suit the new arrangement.

The aero fire alarm system is fitted throughout the passenger and crew accommodations while the Rich system has been installed in the cargo spaces.

The entire work was carried on under the direction of Captain R. D. Gatewood, manager, Maintenance and Repair Department, United States Shipping Board. Plans and specifications, which were noteworthy for their completeness and conciseness, were prepared by the technical staff of the United States Lines, under the supervision of Mr. Carl E. Petersen, naval architect of the United States Lines, and Mr. A. D. Woods, naval architect of the United States Shipping Board, both of whom also supervised the work of reconditioning. Mr. B. D. Pender, assisted in the reconditioning work, having charge of all furnishings and stewards equipment.

Only Ships Best Meeting Requirements Are Efficient

Navy Design Methods, Allowing Several Basic Solutions,
Could Be Used Advantageously in Merchant Marine Practice

By James L. Bates*

A NUMBER of years ago Rear-Admiral W. L. Capps, then Chief Constructor of the United States Navy, gave this advice to the writer: "Young man, it is better to be conservative during the design period than to be sorry on the trial trip." Doubtless the idea thus expressed is familiar enough. In fact, its very familiarity testifies to the general prevalence of dangerous optimism in design. However, in spite of the appreciation of the serious consequences involved, recurring instances prove that over-confidence, lack of thoroughness, even ignorance, are far more prevalent among us who design and build ships than we care to admit.

The following seven instances, all occurring within very recent years and in many cases coming under the personal observation of the writer, will serve to illustrate the nature of these shortcomings.

CASE NO. 1

A vessel intended for a familiar service, one in which hundreds of vessels have successfully operated for years, recently went on her trials and realized about $\frac{1}{2}$ her designed

speed. Investigation showed a very poor form of hull for driving, very light, high speed machinery for the kind of service, propellers of inadequate diameter and area, and an underbody form and shaft location which rendered a material increase of propeller diameter very difficult, if possible at all. Her performance was ultimately improved after changes had been made in machinery and propellers; but this improvement was realized at considerable expense to the owners, both because of the actual cost of the changes and because of the loss in income due to the vessel's enforced idleness.

CASE NO. 2

After successfully running for some years, a vessel was taken out of service to be fitted with a new and much heavier machinery installation. Deep longitudinal girders were built into her hull, and everything was nearly ready for the actual placing of the machinery when it was discovered that several of the heaviest longitudinal strength members were cut in the vicinity of the forward quarter point. An investigation showed that at this point an excessive concentration of stresses might be anticipated, particularly when being driven into a head sea. Compensation

*Author of Basic Design; in Charge of Basic Design Section, Bureau of Construction and Repair, Navy Department, Washington, D. C.

was designed and fitted with satisfactory results, but at the cost of much worry and some expense and delay.

CASE No. 3

An oil tanker was built, standard in type and in nearly all features of construction, but she had great beam and nearly twice the metacentric height usual in vessels of her type and size. This vessel at sea developed a complete period of roll of from 7 to 8 seconds. After several seasons in service the ship's structure showed signs of serious racking.

CASE No. 4

A cargo vessel was built, slightly larger than her predecessor also built in the same yard. In service she showed insufficient stability. Consequently, she has carried during her entire life a large amount of permanent ballast, a dead loss in cargo capacity.

CASE No. 5

A vessel was designed for passenger service. When the plans were well advanced and construction actually begun her prospective owner decided to put on an additional complete deck in order to increase her accommodations and, incidentally, their own income. The additional deck was fitted, but no change made in the original underbody. In service the vessel was very tender, nearly always requiring water ballast and the most constant attention to keep her upright.

CASE No. 6

A completed vessel went on her trials and failed to make her speed. The contract provided a money penalty for such failure. A careful investigation, which was undertaken to ascertain the reasons therefor resulted in the discovery that the trial had been run in shallow water, which in itself put the vessel at a disadvantage, and that the form of hull aft was such as to render the propellers very inefficient. Of course, the trial could be run again under proper conditions, but the hull form could not be altered. Therefore, the inefficient hull must be driven during her entire period of service.

CASE No. 7

An expensive yacht was built of materials unsuited to service in salt water. This vessel literally fell to pieces, becoming a total loss.

Such mistakes not only increase the original money outlay, but frequently decrease the ship's earning power throughout her life. They are generally chargeable to faulty design. In some of the above cases the naval architect, and in others the marine engineer, was the culprit. Different reasons could be given for such failures. Poor judgment or lack of knowledge is sometimes the cause. Sometimes an unwillingness on the part of the business men involved to secure expert advice because of the added expense, or an anxiety to hurry the job into production at the earliest moment is responsible. Attempts to utilize previous unsuitable designs as the basis for the new, or to crowd too much into limited dimensions, are sources of trouble. The important facts are that such serious failures, and many more like

them, have occurred, and, knowing them, we should do our best to prevent their repetition.

GIVE MORE TIME TO EARLY STAGES OF DESIGN

The writer believes that more time given and more attention paid to the early stages of design will assist materially in increasing the efficiency of our shipping because it will guard against mistakes such as those above described. Such a claim appears reasonable enough when one reflects that this, the preliminary design period, is the period in which type, size, power, dimensions, etc., are fixed, and that the work of detail design subsequently carried out is, to a large extent, a matter of routine which, with moderate care and intelligence, will be satisfactory. By devoting relatively more time to the consideration of these principal features and their proper relation one to another, not only is more rapid progress during the detail design period assured, but a greater assurance that the final result will be satisfactory is obtained.

FORMER NAVY METHOD

The development in the preliminary design of ships which has taken place in the Bureau of Construction and Repair, Navy Department, during the past fifteen years will serve to illustrate these points. When the first of our all-big-gun battleships was designed it was the practice to select type and dimensions and proceed at once to prepare a general arrangement layout to a scale of $1/16$ inch = 1 foot. This layout was made in considerable detail, including profile, deck and platform plans and type sections. All the main structural and many minor bulkheads were shown. The assignment for the use of the principal compartments was indicated. Boat stowage was worked out. Gun positions for both main and secondary battery were fixed. An approximation to the weight and center of gravity was prepared. If this showed satisfactory results, the plans, together with the necessary descriptive matter, were forwarded to the Department for examination, comment and approval. The considerations of strength, cruising radius, and even speed and power were somewhat superficial being largely left for a later date. The data presented were carefully considered by the Department and returned to the Bureau. The comment made, as might have been expected in view of the character of the information furnished, was in great detail, frequently covering such minor items as the location and arrangement of offices, pantries, etc. In other words, both in the Bureau and the Department, much time and attention was given to detail at a period in the design when all the consideration should have been given to features of more general importance. The result was that but a very few solutions to a given design problem could be worked out with the time and force available, and that but a small portion of the possible field could be adequately covered.

PRESENT NAVY METHOD

At the present time the problem is attacked with the idea of developing the possibilities of a number of different designs and presenting them in comparable form so that

These methods and suggestions, valuable as they have proven in the work of the Navy Department, where so many types and sizes of vessels must be investigated that it is necessary to employ certain men almost constantly for the purpose, may not prove of such value to private concerns where the problems which require such investigation are less numerous. Nevertheless, the naval architects of these concerns and as many of their assistants as necessary should be thoroughly familiar with these principles and the methods of applying them efficiently so as to be able to perform this work when required. Organizations which are not warranted in employing regularly a force qualified for such work will serve their own best interests by securing competent advice when needed.

a design may be adopted, not merely because it has been prepared and meets the requirements, but because it has been shown by comparison with a sufficient number of others to best meet the requirements.

The work is carried out in a logical series of steps.

First, a displacement suited to the type of ship and the armament, protection, and machinery contemplated is selected.

Second, a length suited to the speed and displacement is adopted.

Third, a depth sufficient for a satisfactory strength girder and a proper arrangement of decks is selected. Suitable midship scantlings are also outlined.

Fourth, a beam which will insure adequate stability and a reasonable period of roll is picked.

Fifth, a suitable form of underbody is chosen and an estimate of the power for the desired speed worked out.

Sixth, a small scale plan (from 1/50 inch to 1/100 inch = 1 foot), showing general arrangement of the principal features and giving the principal characteristics in tabular form, is prepared.

Seventh, a preliminary body plan for use during the preliminary design stage and suitable for the preparation of a model for towing in the experimental basin is made.

Eighth, an approximate estimate of weight in the several conditions of loading is made.

The above is as accurate a statement of the usual procedure as can be made. As a matter of fact, it is usually necessary to take some of the steps simultaneously in order to insure maintaining a proper relationship between them.

STANDARD FORMS USED

Standard forms have been prepared for use in connection with the above steps so as to secure a proper order of procedure and minimize the possibility of omitting any of them.

Special compilations or arrangements of data have been prepared so that these various steps may be taken with a minimum of effort and with minimum danger of error.

The seventh step is sometimes omitted or only partially carried out if the urgency of the case demands that it be taken into consideration.

When the sketch plan and the data connected therewith are complete all the information available is tabulated upon standard sheets so that it is readily comparable with similar information previously tabulated for other vessels of the same type and similar size. Such comparisons are very valuable in the discovery of inconsistencies and in bringing out points of difference.

Under this system it is possible to prepare data for submission to the Department upon very short notice, and these data are much more complete and reliable insofar as basic considerations of importance are concerned than were those submitted under the old method. Moreover, the effect of the present method is to center attention on the more important features and to relegate to their proper time and place matters of detail arrangement and construction.

RESULTS OBTAINED WITH THIS METHOD

An idea of the character of the results obtained in the design of naval vessels by the use of these methods may be obtained from the following instances:

A battleship had been tentatively outlined as to displacement, dimensions and power. As the result of investigation, her length was materially decreased, her draft increased and her power slightly increased, these changes combining to effect a reduction in the required displacement of nearly 5 percent without the sacrifice of any important feature as a consequence.

A submarine which had already passed through several

different stages of investigation was altered in her curve of sectional areas, and her waterline forward was changed so that her speed was increased about 7 percent without any increase in power.

A vessel of a given displacement and fairly well outlined design was given careful consideration from the standpoints of form of underbody and arrangement of strength members and of scantlings. The changes made resulted in increasing the ship's battery by 25 percent without sacrificing other features of value.

APPLICATION TO MERCHANT MARINE

The application in principle, at least, of the previously described ideas should prove beneficial to many design organizations. In order, however, to realize the fullest benefit therefrom there should exist a clear conception of the essential differences between the general and the detail considerations of design; a realization of the number of solutions possible for any design problem, and an appreciation of the facilities offered by properly worked out preliminary design methods for bringing out the salient features of the different solutions in their proper relations.

A competent technical staff trained to the viewpoint of the preliminary designers should be available. This is not so simple a requirement as it might at first seem. It is frequently difficult, sometimes impossible, to educate the man, who has spent years in acquiring an accurate knowledge of the details of ships, to ignore them temporarily in order to deal with the general features such as type of ship, hull form, power, etc.

VALUE OF EXPERIMENTAL MODEL BASINS

There must also exist an appreciation of the value of and a willingness to utilize the facilities of experimental model basins, testing laboratories, etc., or at least to secure advice and information from representatives of such organizations or other experts relative to features or appliances not previously handled and definitely understood.

Each organization will increase its efficiency by carefully arranging all its available data in convenient form for ready reference, as well as by utilizing published data closely applicable to the problems of the especial field which they cover.

In the Bureau of Construction and Repair, Admiral Taylor's "Speed and Power of Ships," Professor William Hovgaard's "Structural Design of Warships," the writer's "Basic Design of Modern Vessels," published as part of the "Shipbuilding Cyclopaedia," as well as numerous articles published in the technical press or read before technical societies, are constantly used for reference in the solution of problems to which they apply.

Liability for Personal Injury Fixed by Maritime Law

IN *Payne vs. Jacksonville Forwarding Company*, American Maritime Cases Vol. 1, page 524, the libellant was chief engineer of the *S. S. Harrish*, which had run aground, and was injured while voluntarily assisting the crew of a tug in making fast a line to the *Harrish*. The tug surged ahead, the line broke and libellant was injured. He filed a libel against the owner of the tug charging negligence. The Court said, that since this is a maritime tort respondent, liability is fixed by the maritime law and not by the Hazardous Employment Act of Florida and therefore this being a suit by a seaman for damages and not for maintenance and cure and wages, the negligence of the master is no ground for recovery, as section 20 of the Seamen's Act of March 4, 1915, does not make the shipowner liable for the master's negligence.

Typical Standard Oil Tanker

Notes on Efficiency in Operation of Oil Tankers

Proper Design for Specific Trade, Upkeep and Eternal
Vigilance Over All Divisions of Operation, the Vital Factors

By Townsend J. Smith*

OF the various types of ships which make up the American Merchant Marine, the oil tanker is the type at present having the greatest percentage in service. Any economies, therefore, which may be attained with these vessels will have a proportionate influence on the whole. In a broad sense, the efficient and economical building or operating of tank steamers offers the same problems as does any other fleet, but there are certain points which require particular attention, due primarily to the kind of cargo carried and the short periods allowed in port for overhaul, running repairs, reception of stores, etc.

As a first consideration, it is well to have a clear understanding of what it meant by "economy." Economy is defined in the dictionary as "thrifty and careful administration," and "management without loss or waste." This describes exactly the ideal of every builder and operator, but the actual obtaining of the condition, where there is no loss or waste, is still in the future.

Economy is not necessarily a minimum money expenditure, although many a famous and prosperous steamship company has been managed so that one shilling has worked overtime and done the work of two, but economy can best be promoted by a careful watchfulness that expenditures are only made for items which have a present or future value. Thus it is the best of economy to have spare steering gear worms or segments in stock, as these parts, from experience, are found to require renewal at times, but it would be very poor economy to keep a spare bed plate for the same engine, a part which is generally good for the life of the ship.

In the search for true economy, we may divide the subject into three sections:

1. First cost,
2. Repairs and maintenance,
3. Operation.

PROPER DESIGN ESSENTIAL

As has been often stated the real economy in first cost is found where the vessel is carefully designed for a certain

trade and built as large and as powerful as the trade demands, but no larger and with no great excess of reserve power; power which will seldom be needed. In tank steamers the result of experience must go hand in hand with the best guess as to the future; for guess it must be to a large extent, with old oil fields and areas constantly going dry and new fields in distant parts of the world opening up daily. One way to anticipate these changes is to design the vessel so that alterations may easily be made, should occasion arise to put the ship in another service from that originally planned. In some cases it is well to provide extra large heavy duty pumps and heater coils for heavy cargo although gasoline may be the oil generally carried. Each oil company has its idea as to how far to provide for future contingencies, as each has its preference for type and size of ship.

To enter into the relative advantages of Diesel and steam driven tankers is to enter a discussion which can not be definitely answered now. Here again preference, or its half-brother prejudice, may enter in. So far it would seem that the human factor operating has as much or more to do with results than mechanical refinements.

Consumption of fuel down to .304 pound per indicated horsepower hour, of lubricating oil to .00255 pound per indicated horsepower hour, and a cost of fuel and lubricating oil down to 5.63 cents per 1,000 ton-miles, as recently reported for a 15,000-ton tank motor vessel, appears very attractive if these figures tell the whole story of expense entailed with motor operation.

As a practical question we need not be greatly concerned as to the kind of power outfit of new tank ships as the world seems well supplied at present.

The conversion of steamers to motor drive is a special condition requiring particular consideration for each case.

TONNAGE MEASUREMENT

A point sometimes overlooked in this country, perhaps not so much in recent years as formerly, is the tonnage measurement, a fee which is a fixed charge as long as the ship is

*Standard Transportation Company, New York.

navigated and may even form a basis for taxation when the vessel is laid up. Any reduction possible here in structure or arrangement, even if it requires alteration and read-measurement after building, is well worth looking into.

With the competition in American yards as keen as it is at this writing, any suggestions as to cutting down prices are apt to draw out remarks "not only loud but deep." However, it would seem that the cost of auxiliaries and their repair parts are out of line (as the stock brokers have it), with the cost of other component parts. This point has recently come to the fore in British yards also. There is a wide range in the first cost due to the various standards of owners with regard to outfitting, extra parts carried, reserve stores, etc. These are often overestimated and if the ship trades to ports with ordinary sources of supply and with ordinary repair facilities, much may be done to cut down expense here.

The form of hull and disposition of machinery has become, if not standardized, close to it, not so much from theoretical considerations as from experience. The present day practice of locating the machinery aft has much to recommend it and leads to a fairly good distribution of strain in the loaded vessel. The necessity of removing the thrust block and possibly an eccentric, when drawing the tail shaft, together with rather restricted handling room, are the detailed objections.

REPAIRS AND MAINTENANCE

Proceeding on our second line of inquiry, economy in repairs and maintenance, we find the following sub-divisions, all fluctuating widely at different times, with different owners, and with different types of ships:

- a. Ordinary upkeep.
- b. Bottom painting and under water care.
- c. Attention to "damage and accidents."
- d. Insurance surveys, and governmental examinations.
- e. Carelessness.
- f. Obsolescence.

ORDINARY UPKEEP

Any structure exposed to the elements is bound to suffer wear and corrosion, the principal cause of wastage in a steel structure must be guarded against. Paint of a good quality is the usual retarding agent employed but it is more than wasted unless the surfaces to which it is applied are dry and free from scale. Scaling in itself is not an attractive job and unless someone with good eyesight is employed to follow up this work, corners and backs of reverse bars, clips, surfaces above a man's reach, etc., are very liable to be brushed over without regard to the condition, and corrosion still goes on unchecked.

The preservation of wood decks by recalcing after a year in service and the paying of the seams with a proven composition is of greater value than merely the saving on the wood, as once water finds its way through the seams, the plating below starts to corrode.

Although it would seem unnecessary to call attention to this, the keeping free of wildcats, valves, roller chocks, goose-necks, etc., is an important point as the failure of these to function means just so much first cost locked up without a return in service.

UPKEEP DEPENDS LARGELY UPON PERSONNEL

Ordinary upkeep is a matter partly in the hands of the shore staff but the actual work is largely in the charge of the ship's officers, so that a fresh coat of paint may cover many a fault or it may be the sign of a most intelligent superintendency and care.

Up to the present no satisfactory paint or solution has been found which can be used on the interior surfaces of a cargo tank. Many oils are corrosive in action; especially those containing sulphur, so that in tank vessels, corrosion

and scale are generally found on both sides of the shell and bulkhead plating. With a vessel continually in "heavy" oil service this scale forms more slowly and is not so detrimental as when it is on the surfaces of "light" oil tanks where particles or slabs of rust dissolving may cause a cargo to be off color; or if not dissolved, may find its way under valve seats and discs causing "mixed cargoes," reports of leaky valves and pipe lines. In general it will be found that straight way brass mounted gate valves, with renewable discs, hand holes, etc., give the best service here, although the British have a strong leaning toward the globe valve with its more tortuous passage but more easily ground in seat.

Pipe lines are generally found to go first outside at the threaded ends and here a rust proof mixture will prolong the life somewhat. Another scheme where lines have rusted due to drainage lying in the bottom is to turn the pipes 180 degrees, but it is questionable if the saving in doing this is worth while.

BOTTOM PAINTING AND UNDER WATER CARE

The question of dry docking and painting under water body is the same with tank steamers as with other vessels. Where certainty of route can be assured, once in eight months makes a schedule frequent enough to allow examination of under water fittings, etc. Renewal of the protective zinc slabs will probably be necessary then. These have proven their worth and, even with steel or iron propellers, should be fitted to combat the action of the couple set up by steel of hull, tips of blades and brass in stern bearing. Bronze studs in sea chests are worth the expense, but it is questionable if entire bronze strainers are worth while.

Painting at night is a very uneconomical performance for many reasons and is only resorted to under great stress.

ATTENDING TO "DAMAGES AND ACCIDENTS"

One item which may need close attention, in fact generally receives it, may be classed as those miscellaneous damages caused by tugs, lock walls, bridge abutments, barges alongside, etc. If serious they are generally surveyed and permanently repaired but if not, especially if the owner's agents are responsible, the repairs, due to shortness of time in port, are "put off until next trip." Generally any damage near an oil tight bulkhead, sea connection or scupper is repaired. In course of time these damages taken all together may amount to a very considerable item.

This brings in the question of steaming and cleaning tanks, a very expensive operation, the cost of which may run up to double or quadruple the direct cost of repairs. However work should never be taken in hand until the tank in need of attention and the one each side of it has been certified. The drainings from pipe lines, valves and pumps should be disposed of or these parts blanked off while repairs are in progress. So important is this that the authorities in many British ports require a chemist's test to be made and certificate to be issued each working day. As is well known the liquid cargo is comparatively harmless when open to the air but the gas generated is highly explosive, lodging in the corners, behind brackets, valve pockets, under loose scale, etc. No amount of care can be considered excessive.

Some of the tank cleaning superintendents have become so expert that they have been reported to have struck a match in the tanks so that the chemist would have a good sample. No better display of self-confidence can be imagined.

INSURANCE SURVEYS AND GOVERNMENTAL EXAMINATION

The classification survey is another division where economy is best served by care in the original design as to accessibility, minimum of structural parts and attention to the immediate making good of small damages, etc. The drawing an examination of tail shaft, opening up of pumps, sea valve and the machinery survey in general, follow the usual line. The testing of tanks if the rules are followed literally

a time and money consuming operation, but the societies accept the filling of alternate tanks with cargo as a bulkhead test and are generally liberal in their interpretation of the rules with bona fide owners, recognizing that the time element is most important. The survey periods on many tankers were entirely disorganized during the war, but there is no record of more than normal wastage in this period, which speaks well for their previous upkeep and condition.

With British ships the Board of Trade, while careful of the safety factor and seaworthiness of the ship, is not concerned with details and ordinary good practice may be assumed as receiving their sanction.

The United States Steamboat Inspection Service requirements, while not directed so much as to the cargo in tank vessels, are particularly explicit as to requirements for the bunkers and oil burning equipment, so that not many special economies can be made in the original installation and duplication of heaters, strainers, etc. It is not good economy to aim at simplifying the piping by too much interchangeability of pump services, especially should bilge and fire lines be independent of cargo piping, with no cross connections.

The United States annual steamboat inspection ruling that the cargo should be out of the vessel when undergoing inspection works a particular hardship on tankers. The original motive behind the requirement was probably to determine the condition of the ship's interior structure, but this is usually impossible on account of gas remaining from the cargo. The fact that the bulkheads are spaced so much closer than with other cargo vessels insures seaworthiness and this empty ship ruling might well be rescinded.

CARELESSNESS

It is safe to say that 50 percent of the accidents to personnel, auxiliaries, cargoes, etc., are due to carelessness, pure and simple. This is a matter which is partly controllable but with ever-changing crews not possible to eliminate. Accidents are unavoidable but errors of the same kind must not be repeated by the same people. The great danger lies in the mixing of the cargoes from various tanks through wrong manipulation of valves. It is usual to paint hand wheels of valves for different services distinctive colors and it has been suggested as a further precaution for night handling that they be of different shapes; hexagonal, square, offset vertically, etc. A very definite line of demarcation as to the duties of deck and engine room crews must be insisted on in all matters pertaining to pumping cargo.

In speaking of carelessness we can go one step further and include sabotage, which, while not very often experienced, should be borne in mind.

OBSOLESCENCE

This term includes not only physical deterioration but more especially the condition arrived at after several years' hard service or when trade conditions have changed. This means in a tanker that the pumps and pipe lines are too small, loading and discharging facilities limited, speed below modern requirements and cargo capacity too small for up-to-date shore receiving and storage plants. Types too are superseded. From the original tank ship until recently the poop, bridge and forecastle ships were used, but now only shelter deck ships are considered in the larger types. These in turn may be replaced by another style in the future. The whale-back is in the classic example of a fad, which, while not by any means a failure, was not suitable to survive in competition with more normally formed hulls.

OPERATION

Arriving at our third division, operation, here we have an intangible target to shoot at, as no standard can be laid down as absolutely the point of 100 percent efficiency. The following sub-divisions as recently stated give normal figures for operation excluding corporate overhead and taxes:

	Percent
Depreciation (5 percent of value)	6.7
Interest (5 percent of value)	6.7
Insurance (at 3.75 percent of value)	5.1
Repairs	11.6
Wages	21.2
Subsistence	4.2
Fuel	33.6
Stores and equipment	9.4
Miscellaneous	1.5
Total	100.0

That these percentages are fixed for any one ship or fleet for any considerable time is open to question.

Various standards of efficiency have been proposed when putting ship against ship, such as ton-mile cost, tons carried per year, maintenance of repair cost per deadweight ton, etc., etc., many of which depend on the personal opinions of the compiler. Any comparison embracing net tonnage is of no use whatever, as net tonnage is an arbitrary thing with no real relation to the size of "ableness" of the vessel.

The elaborate theoretical tables and formulæ sometimes developed which give a numerical index of performance are not to be depended upon, as they require figures and costs seldom available in a form to be used in combination with technical matters and it is hopeless to expect the purely actuarial and engineering divisions to agree on the relative importance of each other's points or data, even should time allow an extended analysis. The action of the U. S. Shipping Board in building up a staff of research and trial experts is a move which might well be followed by private companies, provided the result of such inquiries were promptly put into practice and not made merely the contents of some enthusiast's data book.

The two largest items in the cost sub-division above are wages and fuel. The costs in both cases are set by general conditions over which the operator has small control and his only hope for economy is in using his labor to the best advantage with his fuel at a minimum, viewed from every angle.

The subject of careful fuel burning with both coal and oil has received much intelligent attention and experiments of all kinds are constantly in hand. The literature here is very extensive, so much so that many of the fuel oil advertising catalogues might well be used as text-books in thermodynamics. With few exceptions any of the good fuel burning systems will bear comparison with any other.

The same spirit of inquiry has been shown lately with regard to economical handling of feed water heaters, superheaters, electric auxiliaries, etc., improvement in any one of which is a subject too large for this article.

In tankers, the cargo pumps may be considered the heart of the outfit and the pipe lines the arteries. Compound pumps have not found extensive favor in spite of their lower steam consumption in theory. Up to the present 12 inches is the most convenient pipe size for main lines in a large ship with 8 by 10-inch discharges. One detailed source of loss both in fuel burned and in material wasted occurs when the insulation of deck piping is carried away by seas. This damage the shelter-decker escapes. Ordinary covering is short lived and with a double pipe arrangement the effect is often just the opposite to the designer's intention, due to water-lodging in the outer casing. This is only one point of the many that will occur to any one who has ever dealt with this class of ship.

To repeat what was stated at first, there is no easy road to economy and with every care one year's showing may be very poor when matched against another's, since absolute standards are impossible and a thousand factors enter the problem. It is a subject not taught in the books although books may show the path.

To sum up: Eternal vigilance is the price of liberty—from extravagance and a deficit.

Applications of Arc Welding to Ship Construction—II

Details of Welding Construction—Repairs to ex-German Liners — System for Designating Types of Work

By E. H. Ewertz*

THE Electric Welding Company, Gothenburg, Sweden, constructed in 1920, the first electric arc welded ship in that country. This was a tugboat 52 feet 6 inches long, 13 feet 6 inches molded breadth and 7 feet molded depth, having a draft of 3 feet 6 inches. The construction

*General Manager, Moore Plant, Bethlehem Shipbuilding Corporation, Ltd., Elizabeth, N. J.

Fig. 22.—Profile and Half-Plan of Dairyo Maru

was in accordance with Lloyd's rules for riveting but welding was used throughout, eliminating practically all riveting. No recent report is available as to her performance.

About the time this tug was built in Sweden by the Electric Welding Company, a similar size tug was constructed by licensees of the Kjellberg system in Caen, France.

From the shipyard of Kyle & Purdy, City Island, New York, N. Y., a torpedo boat was launched in December, 1920, called the *Sea Hornet*. She was really a motorboat, 58 feet long, with a 600 horsepower engine having a speed of about 35 knots and a cruising radius of 800 miles. This boat was constructed of No. 10 gage steel plates, having 1 inch by 1½ inch angle frames. Bulkheads were fitted so as to make her practically non-sinkable. Electric arc welding was used throughout for all joints, the shell being all butt welded so as to leave a perfectly smooth surface. Thousands of miles have been covered by this motorboat up and down the Atlantic Coast in all sorts of weather and after ten months' service no defects were found.

Fig. 24.—Watertight and Partial Bulkheads of Caisson

Fig. 25.—Repair by Arc Welding of Difficult Break on First Intermediate Pressure Cylinder on S. S. Pocahontas (ex-Princess Irene)

In Japan we find the electric arc welding used extensively in new construction as well as in ship repairs. The Mitsubishi Dockyard and Engine Works at Nagasaki are licensees of the Kjellberg arc welding system, and in a paper read by Mr. M. Haramiishi, general manager of the Kobe plant, before the Japanese Society of Shipbuilders, we find that in 1920 they undertook the conversion of the steam trawler *Dairyo Maru* into an oil lighter, capable of carrying about 300 tons deadweight.

HOW RECONDITIONING WAS DONE

This trawler was 95 feet long with a beam of 26 feet, and a depth 12 feet 6 inches. The wood deck, longitudinal bulkheads, bunker, casings, engine and boiler foundations as well as deck houses, funnel, mast, deck and engine machinery, piping, shafting, etc., were removed and six new oil tight bulkheads, forming two cofferdams and five oil compartments, with an expansion trunk extending the full length of the oil compartments were installed. New bulkheads were fitted, floors and reverse frames were removed and new bulk-

heads welded to the frames with a continuous weld to the shell and bulkhead on one side and tack welded on the other side. Deck plating was butt welded both on the ends and sides of the plating. Also the original stringer bars were cut out, the holes welded up and stringer plates welded to the shell plating. Reinforcing angles were fitted on the underside of the stringers between frames.

The expansion trunk side plating was connected to the deck with angles having full welds, heel and toes. Stiffeners of flat iron were welded on edge to the side plates. The trunk top plating was riveted to the beams and full butt welded at seams and butts. Oil hatchways were formed by angles having corners cut out and bent to form the square. This bar was welded heel and toe, and the hatch cover hinges and fastenings were tack welded on the edges, no holes being used, thereby eliminating any possible trouble of leaks. Bulkheads were welded much the same as deck plating. After completion, the tanks were tested with a 6 foot head, and some slight leaks were found where overhead welding had been used but these leaks were made

Fig. 27.—Section of Naval Capital Ship, Showing Bulge

tight by calking. All the work performed on this boat has proved entirely satisfactory to the owner of the vessel.

ELECTRIC WELDED CAISSON

Another very interesting construction where electric welding was used for practically all joints was the steel self-floating caisson for the 460 foot dry dock at Hikoshuma Dockyard. Brackets for frames and beams were butt welded. The hold stringer plates were tack welded to the shell and frame and web frames butt riveted to the beams. Deck

Fig. 29.—Boiler Tubes and Flues Welded to Tube Sheet

Fig. 30.—Setting Patch in Firebox Flush

stringers were fastened in the same way as the hold stringer except where watertightness was called for, in which case, angle bar connections were used to the shell with the seams

Fig. 28.—Doubling Plate in Way of Opening in Ship's Side on a Riveted Vessel and an Approved Method of Compensating for a Similar Opening by Welded Doubling Pieces

Fig. 31.—Details of Welding for Oil Fuel Tanks

Fig. 32.—Arrangement and Details of Welded Condenser

and butts welded. In order to facilitate laying of the wood deck, all plating was butt welded leaving a flush deck. Bulkhead plating was fitted horizontally and it was lapped and full welded on the upper edge with tack welding on the lower edge. Bounding bars were full welded to the bulkheads but riveted to the shell. Trunks were plated vertically with corners and the butts were welded. All anglesmith work was practically omitted by the use of angles having corners cut out and welded either with or without filling in the corner of the cut flange. Doubling plates around manholes and

other stressed places were full welded along the edges with no holes for rivets. Floating plates and diaphragm plates were welded direct without the use of angles. All rail stanchion sockets, steps, eye pads and similar fittings were placed in position and tack welded. Fastening bolts for wood fenders were welded to the shell plating without penetrating the shell. All welded laps of plating were the width of a single riveted lap.

The report from the Dockyard is to the effect that the

Fig. 33.—Part of Boiler Furnace Cut Out and New Piece Welded In. Several Cracks V-ed Out and Welded

Fig. 34.—New Plate Welded in Combustion Chamber Back and Crack V-ed Out and Welded

Fig. 35.—Water Storage Tank

"caisson is working very well without giving any trouble at all."

WELDED PONTOON FOR CRANE

The Kobe plant has constructed an all electric welded floating crane pontoon 65 feet long, 35 feet molded breadth, and 8 feet molded depth, having a rectangular form in cross sections and deck plan with the bottom plating at both ends curving upwards with a 30-inch radius. The plating is $\frac{5}{16}$ to $\frac{1}{4}$ inch thick, all joints being butt welded. Plating is stiffened by flat bar frames $3\frac{1}{2}$ inches by $\frac{3}{8}$ inch spaced

Fig. 36.—Flanges for Pipes

Fig. 39.—Applications of Arc Welding to Ship Construction

Fig. 40.—Applications of Arc Welding to Ship Construction

30 inches apart, and tack welded to the plating. Fore and aft as well as athwartship bulkheads are used for additional stiffening. Insofar as possible, overhead welding was avoided by building up large sections on the ground, and

Fig. 41.—Interior of Welded Engine Room Skylight

Fig. 42.—Exterior of Welded Engine Room Skylight

Fig. 43.—System of Designating Types of Welds

Fig. 44.—Type of Joint: Strap Weld

A strap weld is one in which the seam of two adjoining plates or surfaces is reinforced by any form or shape to add strength and stability to the joint or plate. In this form of weld the seam can only be welded from the side of the work opposite the reinforcement, and the reinforcement of whatever shape must be welded from the side of the work to which the reinforcement is applied.

BUTT

SYMBOL 

Fig. 45.—Type of Joint: Butt Weld

A butt weld is one in which two plates or surfaces are brought together edge to edge and welded along the seam thus formed. The two plates, when so welded, form a perfectly flat plane in themselves excluding the possible projective caused by other individual objects as frames, straps, stiffeners, etc., or the building up of the weld proper.

LAP

SYMBOL 

Fig. 46.—Type of Joint: Lap Weld

A lap weld is one in which the edges of two plates are set one above the other and the welding material so applied as to bind the edge of one plate to the face of the other plate. In this form of weld the seam or lap forms a raised surface along its entire extent.

then erecting. Mention is made of their difficulty to entirely avoid buckling of the light plates but that a copper-smith's skill of judging where cuts should be made to relieve stresses enabled them to eliminate these buckles and leave a smooth finished job.

Many other ships, all or partially welded, could be mentioned here, such as the 52-foot barge built by the S.O.S. Welding Corporation of Brooklyn, N. Y., or the 172-foot battle towing target constructed at the Norfolk Navy Yard, but we believe the data given will be sufficient to form a proper background to build on.

The use of electric arc welding in ship construction, aside from joining what is known as main strength members, such as shell and deck plating, keelsons, stringers, main bulkheads, etc., is very extensive and shipbuilders are familiar with such work, at least, to a limited extent.

MACHINERY REPAIRS ON EX-GERMAN LINERS

One of the most spectacular electric arc welding jobs was the repair of the main propulsion machinery on the German ships taken over by our Government when war was declared

FILLET

SYMBOL 

Fig. 47.—Type of Joint: Fillet Weld

A fillet weld is one in which some fixture or member is welded to the face of a plate, by welding along the vertical edge of the fixture or member (see "welds" shown and marked "A" on illustration). The welding material is applied in the corner thus formed and finished at an angle of 45 degrees to the plate.

PLUG

SYMBOL 

Fig. 48.—Type of Joint: Plug Weld

A plug weld is one used to connect the metals by welding through a hole in either one plate (Fig. "A") or both plates (Fig. "B"). Also used for filling through a bolt hole as at (Fig. "C"), or for added strength when fastening fixtures to the face of a plate by drilling a countersunk hole through the fixture (Fig. "D") and applying the welding material through this hole, as at (Fig. "D"), thereby fastening the fixture to the plate at this point.

on Germany. The machinery had been demolished by the crews of the ships with the hope, at least, of preventing their immediate use, and it was in general the opinion of our engineers estimating on the repairs that it would require about twelve months' time to put the machinery in service. However, under the direction of the late D. H. Wilson of the Wilson Welding and Metal Company, repairs to the various castings were accomplished by the use of electric arc welding.

After the broken out parts were cut out and edges cleaned, steel studs were fitted on the edges of the original castings and broken out parts were replaced by steel castings with edges so beveled to form a V in the original castings, and these V's were filled in with welding material. Then welding was continued from the edge of the inserted pieces to the studs previously referred to; in this way reinforcement was obtained of sufficient strength to withstand the stresses to which these parts are exposed. Due to this method of repairs the former German ships were again in service only a few

Fig. 49.—Type of Joint: Tee Weld

A tee weld is one where one plate is welded vertically to another as in the case of the edge of a transverse bulkhead (Fig. "A") being welded against the shell plating or deck. This is a weld which in all cases requires exceptional care, and can only be used where it is possible to work from both sides of the vertical plate. Also used for welding a rod in a vertical position to a flat surface, as the rung of a ladder (Fig. "C"), or a plate welded vertically to a pipe stanchion (Fig. "B"), as in the case of water closet stalls.

Fig. 50.—Design of Weld: Single "V"

Single "V" is a term applied to the "edge finish" of a plate when this edge is beveled from both sides to an angle, the degrees of which are left to the designer. To be used when the "V" side of the plate is to be a maximum "strength" weld, with the plate setting vertically to the face of an adjoining member, and only when the electrode can be applied from both sides of the work.

months after they had been taken over by the Government. The submarine activities prompted the British Government to fit bulges of steel construction on the outside of the shell plating at and below the water line on a large number of capital Navy ships, and these structures were to a large extent constructed by the use of the Quasi-Arc welding system.

A book could be written on the many important jobs performed during the Great War by the use of electric arc welding. Yet much more could have been accomplished had it been possible to compare data on work performed in the various shipyards as was later found by comparing work done by electric arc welding in the San Francisco plant of the Bethlehem Shipbuilding Corporation, under the guidance of Mr. J. J. Tynan, and work performed by the same company at the Fore River plant through the activities of the general manager, Mr. W. S. Wakeman. Reports and photo-prints of work performed at the various shipbuilding and

Fig. 51.—Design of Weld: Double "V"

Double "V" is a term applied to the "edge finish" of two adjoining plates when the adjoining edges of both plates are beveled from both sides to an angle, the degrees of which are left to the designer. To be used when the two plates are to be "butted" together along these two sides for a maximum "strength" weld. Only to be used when welding can be performed from both sides of the plate.

Fig. 52.—Design of Weld: Straight

Straight is a term applied to the "edge finish" of a plate, when this edge is left in its crude or sheared state. To be used only where maximum strength is not essential, or unless used in connection with strap, stiffener or frame, or where it is impossible otherwise to finish the edge. Also to be used for a "strength" weld, when edges of two plates set vertically to each other—as the edge of a box.

Fig. 53.—Design of Weld: Single Bevel

Single bevel is a term applied to the edge finish of a plate, when this edge is beveled from one side only to an angle, the degrees of which are left to the designer. To be used for "strength" welding, when the electrode can be applied from one side of the plate only, or where it is impossible to finish the adjoining welding surface.

ship repair plants as well as from the welding equipment manufacturers show a wonderful opportunity for this simple method of construction, and the illustrations embodied in this paper give a general idea of what can be accomplished.

SHIP REPAIR WORK

In ship repair activities there is an unlimited field for the use of electric arc welding and work has been performed by welding that would have been impractical without it. Converting a coal burning ship to an oil burning ship and fitting and making oil tight compartments for carrying the fuel oil is an extremely costly and difficult undertaking should

Fig. 54.—Design of Weld: Double Bevel

Double bevel is a term applied to the edge finish of two adjoining plates, when the adjoining edges of both plates are beveled from one side only to an angle, the degrees of which are left to the designer. To be used where maximum strength is required, and where electrode can be applied from one side of the work only.

Fig. 55.—Type of Weld: Reinforced

Reinforced is a term applied to a weld when the top layer of the welding material is built up above the plane of the surrounding material as at Fig. "A" or Fig. "B" above, or when used for a corner as in Fig. "C." The top of final layer should project above a plane of 45 degrees to the adjoining material. This 45 degrees line is shown "dotted" in Fig. "C" above. This type is chiefly used in a "Strength" or "Composite" kind of weld for the purpose of obtaining the maximum strength efficiency, and should be specified by the designer, together with a minimum number of layers of welding material.

Fig. 56.—Type of Weld: Flush

Flush is a term applied to a weld when the top layer is finished perfectly flat or on the same plane as on the adjoining material as shown at Figs. "D" and "E" above or at an angle of 45 degrees when used to connect two surfaces at an angle to each other as at Fig. "F" above. This type of weld is to be used where a maximum tensile strength is not all important and must be specified by the designer, together with a minimum number of layers of welding material.

Fig. 57.—Type of Weld: Concave

Concave is a term applied to a weld when the top layer finishes below the plane of the surrounding material as at Fig. "G" above, or beneath a plane of 45 degrees at an angular connection as at Figs. "H" and "J" above.

To be used as a weld of no further importance than filling in a seam or opening, or for strictly calking purposes, when it is found that a minimum amount of welding material will suffice to sustain a specified pound square inch pressure without leakage. In this "type of weld" it will not be necessary for the designer ordinarily to specify the number of layers of material owing to the lack of structural importance.

we have to rely on riveting and calking alone, but such conversions are relatively simple today with the use of electric arc welding as was clearly demonstrated when Messrs. Armstrong, Whitworth and Company converted the Cunard company's great passenger ship *Aquitania* from coal to an oil burner.

To cut out by gas a damaged part of a ship, fit new parts or repair the parts cut out and then by welding restore it to its former place, retaining the original strength, is just what is done today by the use of electric arc welding and ship-owners are able to obtain more operating days due to cutting down the lay days necessary for repairs, by the use

Fig. 58.—Kind of Weld: Tack

A tack weld is applying the welding material in small sections to hold two edges together, and should always be specified by giving the space from center to center of weld and the length of the weld itself. No particular "design of weld" is necessary of consideration. A tack is also used for temporarily holding material in place that is to be solidly welded, until the proper alignment and position is obtained, and in this case, neither the length, space or design of weld are to be specified.

Fig. 59.—Kind of Weld: Calking

A calking weld is one in which the density of the crystalline metal, used to close up the seam or opening, is such, that no possible leakage is visible under a water, oil or air pressure of 25 pounds per square inch. The ultimate strength of a calking weld is not of material importance—neither is the "design of weld" of this kind necessary of consideration. The operator must be the judge in the number of layers needed for a tight weld, although the designer should specify a minimum amount of layers.

Fig. 60.—Kind of Weld: Strength

A strength weld is one in which the sectional area of the welding material must be so considered that its tensile strength and elongation per square inch must be equal at least 80 percent of the ultimate strength per square inch of the surrounding material. (To be determined and specified by the designer). The welding material can be applied in any number of layers beyond a minimum specified by the designer. The density of the crystalline metals is not of vital importance. In this form of weld, the "design of weld" must be specified by the designer and followed by the operator.

of electric arc welding. Many of the cuts and prints shown herein are of work designed for riveting, with welding substituted, while there are other cuts designed for welding, and it is by the use of the proper design that electric welding

Fig. 61.—Kind of Weld: Composite

A composite weld is one in which both the strength and density are of the most vital importance. The strength must be at least as specified for a "strength weld," and the density must meet the requirements of a "calking weld" both as above defined. The minimum number of layers of welding material must always be specified by the designer, but the welder must be in a position to know if this number must be increased according to the welder's working conditions.

Fig. 62.—Position of Weld

Flat position is determined when the welding material is applied to a surface on the same plane as the deck, allowing the electrode to be held in an upright or vertical position. The welding surface may be entirely on a plane with the deck, or one side may be vertical to the deck and welded to an adjoining member that is on a plane with the deck.

Horizontal position is determined when the welding material is applied to a seam or opening, the plane of which is vertical to the deck and the line of weld is parallel with the deck, allowing the electrode to be held in an inboard or outboard position.

Vertical position is determined when the welding material is applied to a surface or seam, whose line extends in a direction from one deck to the deck above, regardless of whether the adjoining members are on a single plane or at an angle to each other. In this position of weld, the electrode would also be held in a partially horizontal position to the work.

Overhead position is determined when the welding material is applied from the under side of any member whose plane is parallel to the deck and necessitates the electrode being held in a downright or inverted position.

construction will be found stronger and cheaper as well as less in weight as compared with a riveted construction.

In order to simplify the work of designating types of welds on plans in the designing of detail parts, there has been developed by Mr. H. E. Knox, ex-naval constructor, a system of marking of joints for various types of welding, and it is hoped that such a system will be followed in the making of plans of ships or other structures to be constructed by the electric arc welding process.

(To be continued)

During June Shipping Board steamers carried 63 percent of the cotton shipped from Gulf ports to foreign countries. The Shipping Board is now operating frequent sailings from Gulf ports to Continental Europe, United Kingdom, Mediterranean, Orient and Africa.

General Utility Power Smithing Hammer

A POWER-DRIVEN hammer intended particularly for use on forging work ordinarily performed under hand-swung sledges and too small to be done under steam hammers, is shown in the accompanying illustration. The hammer is termed a "mechanical helper," since it replaces the one or two men employed as strikers at each anvil. The same hand tools that the smith ordinarily employs are used with the hammer, without the need of special tools and dies. The hammer, which is stated to greatly increase the capacity and the output per anvil, has recently been placed on the American market by the Blacker Engineering Co., Inc., Grand Central Terminal, New York, N. Y.

The machine is rated to handle material up to 2½ inches thick, although even larger sizes can be cared for. The hammer itself is under the control of the smith, so that either a light or heavy blow can be struck. The force of the blow varies directly with the depression of the treadle extending around the anvil. It is stated that the maximum blow is about four times as heavy as that delivered by a human

Power Hammer for Forging Work

striker, and that the machine attains a rate of 140 blows per minute.

An important feature of the hammer is the lateral traverse motion that can be given to the hammer itself. This motion is controlled by a winged foot lever located at the right of the anvil and enabling the head to be traveled along the face of the anvil to the desired point.

An anvil and a block of special design to suit the hammer are furnished. The base of the anvil is planed and adjusting screws are provided on the stand, to enable the anvil to be moved forward or backward to get the proper position under the hammer.

The hammer requires only 1 horsepower to drive it. It can be run by means of a belt from a lineshaft, being furnished with tight and loose pulleys 15 inches in diameter for this work. A more compact unit is the one driven by an individual motor, as illustrated. The motor is mounted on a small stand on the base and geared to a large driving gear placed on the main shaft. The hammer alone weighs 1,300 pounds, the anvil 560 pounds, and the stand 336 pounds.

Competition for Ship Repair Contracts Keen Between British and Continental Shipyards

Labor Difficulties Hamper Work in the United Kingdom—
Repair Costs from 10 to 36 Percent Lower on the Continent

By W. H. Wendon

WITH the possible improvement in the general shipping position from now onwards—the middle months of the year are notoriously poor ones for shipowners—attention is being paid to the question of ship repairs, an elastic term which includes damage owing to weather or other “casualty,” survey commitments, or so on. In this connection the long-standing competition between United Kingdom and Continental ship repairers is again prominently to the fore. The fact is that, while the United Kingdom has recovered to a marked degree the work which, owing to lower costs in consequence of exchange difficulties, etc., Continental yards had been able to wrest from them, the position is still serious from the point of view of the United Kingdom ship repairing industry.

Apart from the rate of exchange, which is a fluctuating handicap, labor difficulties are the chief source of worry at the moment. The boiler makers, following on the attitude which resulted in the employers having no option but to lock them out, have been responsible for serious delay in repairing boats in the United Kingdom, with the consequence that vessels are constantly diverted to near-by Continental yards.

COMPARATIVE COSTS OF REPAIR WORK

Many instances have just come to light showing the extraordinary disparity between United Kingdom and Continental costs of repairs and periods in which the work can be performed. One of the most interesting is that of the *S. S. Spero*, a boat of 1,960 tons gross, which was damaged, and tenders for the repair of which were invited on account of the underwriters from two German firms, four Dutch firms, one Belgian firm and thirty-one British firms. The tender to specification of a German firm amounted to £17,500, the lowest Dutch tender was £19,500 and the highest £27,000, while the British tenders ranged from £25,800 to £34,500. The underwriters found the difference of £8,300 between the lowest British and German tenders more than their business instinct would stand, and awarded the contract to the German firm.

The placing of the work with a German firm instead of a British one had a most unexpected result. The owners of the *Spero*, the Pelton Steamship Company, of Newcastle-on-Tyne, were indignant that an ex-enemy firm should receive the contract and announced their intention of resisting the underwriters' action in placing the contract with Germans. While nothing more has been heard in regard to this unusual attitude, the incident has served to open up the whole question of repairs as affecting owners, repairers and underwriters.

A leading Lloyd's man gives an instance of the low Continental charges as compared with those quoted by British ship repairers. He states that, when tenders were called for by underwriters for the repairing of a steamer which stranded, nine tenders were received from British firms and two from abroad. The British offers were, with one exception, subject to the cessation of the boiler makers' lock-out, and the time required for the work was between 48 and 60 working days. On the other hand, the two foreign competitors offered to do the work in 32 and 28 days re-

spectively, at prices approximately 10 percent less than the most favorable, and 36 percent less than the highest, British tender.

BRITISH EMPLOYEES OBJECT TO OVERTIME WORK

One of the main factors in the trouble is that employees in the United Kingdom cannot be induced to work overtime, their main plea being that this policy would add to the ranks of the unemployed. It is pointed out to them, however, that when, owing to their action, work is diverted abroad, this entails a dead loss to this country, and it is believed that they are gradually seeing the force of this argument. Overtime is engaged in to an enormous extent in Continental yards, thus facilitating in the competition with British and other “foreigners.” There is another aspect, however, and that is that, while the Continental yards are, as I have indicated, still securing many contracts which, other conditions being equal, would find their way to United Kingdom plants, some of the prices which are being accepted abroad are such as to leave little, if any, margin for profit, so that the question arises: How long will these Continental repairers be prepared to carry on without making a reasonable profit?

Take, for example, one of the leading Dutch plants, Wilton's Engineering and Slipway Company. The directors of this concern remark that “contracts for repair work can only be secured in competition with British firms, and the prices which the company has been forced to accept have been absolutely unprofitable.” During the last financial year the company docked 367 ships, of 1,630,482 tons, while 45 ships, of 138,877 tons, were overhauled in the corporation dry docks. But, most important of all, the company was unable to pay a dividend on its ordinary shares.

The United Kingdom interests concerned are not unnaturally endeavoring to find a way out of the problem to their mutual advantage, and in this regard one prominent ship repairer emphasizes that “the British shipping industry is a trinity of factors that must support each other—the shipowner, the shipbuilder and the ship repairer—in all circumstances and difficulties.” This point has, of course, been made many times before, but there is still every absence of sign that the interests indicated intend to work in any close harmony. They would seem, on the surface, to treat each other's interests as antagonistic to their own. Or is it merely apathy?

VALUE OF STEAMSHIP TONNAGE

A guide, though rather an indirect one, has been afforded to the value of steamship tonnage by the sale by auction in London of seven Chinese-built “standard” steamers. Six of the boats were offered at one time and the other on a separate occasion. In the result, an average price of about £5 per ton on the deadweight was realized, against £36 per ton paid for the boats about four years ago while under construction. In drawing deductions from the result of this shipping sale it should be noted that the prejudice against boats of Chinese construction is understood to be reflected in the price to the extent of a depreciation of 5 or 10 percent as compared with the price of British-built vessels.

TRADE FACILITIES ACTS GUARANTEE

The guarantee, under the Trade Facilities Acts, to the Royal Mail Steam Packet Company, of a sum not exceeding £2,300,000 for expenditure in the United Kingdom on material for three ships to be built by Messrs. Harland and Wolff, Belfast, has led to the anticipated misconception in the minds of many that the guarantee is a "loan." As a matter of fact, it is nothing of the kind. The British Treasury has no power under the Trade Facilities Acts to grant loans, but only to guarantee them. The loan will be raised by the Royal Mail Company, and, to the extent to which it is guaranteed by the Treasury, will be spent by the company wholly in the United Kingdom. It is expected that the new vessels will entail an expenditure of three millions sterling, and the Government of Northern Ireland, under whose jurisdiction, of course, Belfast, where the boats are to be constructed, falls, is guaranteeing the remaining £700,000. One of the boats will be a cargo carrier of about 9,500 tons, while the others are to be passenger ships of about 20,000 tons gross, and will probably be fitted with Harland and Wolff-Burmeister and Wain Diesel engines of the new double-acting type. They are intended for the South American service.

CARRIAGE OF GOODS BY SEA BILL

The Carriage of Goods by Sea Bill, arising out of the well-known Hague Rules, is attracting enormous interest in shipping circles, both in the United Kingdom and all over the Continent. It is permissible briefly to recall that the new legislation proposes to make compulsory in certain contracts of carriage certain rules as to liability, and to make it a criminal offence to come to an agreement not in accordance with these rules. While shipowners, and traders generally, agree that some such proposal is long overdue, there is by no means unanimity as to the need for legislation to effect the purpose aimed at. Hence, the matter has been discussed at considerable length—at the annual meeting in Gothenburg of the Baltic and White Sea Conference, before the Joint Parliamentary Committee specially appointed in the United Kingdom to consider the question, and in other quarters. A leading British shipping authority, Sir Norman Hill, secretary of the Liverpool Steamship Owners' Association, giving evidence before the Parliamentary Committee, told them that the interests of the shipping trade would be best served by permitting the parties concerned to make their own contracts, without being singled out from other concerns, to carry on their business on conditions dictated by a State department. This expert contends that, as the rules regarding sea carriage have been agreed to among the commercial community, no legislation on the matter is necessary, and that, if the rules are not adopted, it will mean that no further international maritime congress can be held. Britain, he thinks, will have made a fool of herself and be laughed at by every other country. Sir Frederick Lewis, chairman of Furness, Withy and Company, endorses Sir Norman Hill's view, but holds that, if the present Bill, which with amendments "represents the greatest common measure of agreement which the business world is ever likely to reach upon this subject," can pass into law in its present form, there is every prospect that the other great maritime nations will without delay enact similar measures.

Opposition to the Rules, from quite a different angle, has been set up by Mr. Robert Temperley, the legal adviser to the Baltic and White Sea Conference. He has carefully examined the report of the Imperial Shipping Committee, and draws the conclusion that the inclusion of "tramp" ships in the scope of the Rules was entirely due to an oversight, and that only liners were readily intended to be within their operation. He agrees that for British shipowners the time for appeal has expired, they being bound in honor to support the Government in giving effect to a pledge to the Dominions. But the Governments of the Continental maritime countries

are, so far as he knows untrammelled by any such pledge, and are free to exempt from this statutory control the bulk cargo trades. Mr. Temperley's arguments certainly meet with approval in some quarters, but in others the question is asked if such action by foreign Governments would be in the interests of British trade and shipping. Mr. Temperley, be it noted, is one of the three witnesses "named" by the Chamber of Shipping of the United Kingdom to give evidence before the Parliamentary Committee, so that the rather remarkable tenor of his views has occasioned more than usual surprise.

Double Service Lantern Adapted to
Marine Service

A LANTERN, combining the functions of a red and white lantern in a single unit, has been made available for marine use by the V. & N. Lantern Company, 256 Broadway, New York. In addition to this feature, demonstrations have shown the lantern to be practically gale proof which makes it desirable as a riding light, a deck lantern, in fact, as a general emergency light for all manner of ship service. The wick control mechanism is such that the flame can be readily adjusted in any wind. The red

The Lantern as Ordinarily Used. Right, The Red Globe in Position

globe is arranged inside the white globe on a threaded metal ring and coiled spring which works inside the shell of the lantern. This ring is controlled by a clip by means of which the red globe may be raised into position when required, or lowered out of sight in the shell.

The lantern is made from cold rolled steel or brass in various finishes—nickel, gun metal, galvanized, etc. The lantern top and lower shell are drawn from a single piece of metal, thus eliminating seams. The guard rings and frames are of heavy construction, spot welded or brazed depending on the material used. The oil font in all cases is drawn from a single piece of brass. It is designed to slip easily into the base of the lantern in any position where, when it is in place, the wick control engages with the top of the well so that when the font is rotated from the bottom, the wick is adjusted up and down. This feature makes it possible to adjust the flame without exposing it to the action of the wind. The top is equipped with a large hinge having a removable cotter pin and locks in place with a heavy spring. The handle fastens directly to the guard frame and is designed to remain in an upright position, or as desired. Either signal oil or kerosene burners are used.

All amendments to the rules and regulations of the Steamboat Inspection Service restricting the age of applicants for license to 21 years have been rescinded.

The 8,000-Ton Medon Built for the Holt Blue Funnel Line

Royal Mail Orders Two 20,000-Ton Motor Liners

To Be Propelled by Burmeister and Wain, Twin-Screw, Double-Acting, Four-Cycle Engines—New Single Screw Motorships

By Our Special London Correspondent

UNTIL about six months ago, it was not generally anticipated in British shipping circles that the oil engine would make much progress in its application to the propulsion of large passenger liners. It was thought that its field would, for some time to come, be limited to cargo ships. A change of attitude has apparently occurred, with the result that owners are not merely considering the possibilities of motor passenger liners, but are actually inclined to favor this type, in preference to the geared turbine ship.

It was therefore not entirely a matter of surprise to those who knew something of these developments to learn that the Royal Mail Steam Packet Company had ordered two 20,000-ton motor liners, which it is believed, will eclipse in luxury any they now possess. No official details have yet been published regarding the dimensions and machinery of these interesting vessels, but the writer believes the following particulars may be taken as correct.

PROPELLING MACHINERY

The length will be about 630 feet, so that these two ships will be considerably larger than the motor liner now being built on the Clyde for the Union Steamship Company, of New Zealand, and which is 600 feet in length. Twin-screw machinery will be installed, and the total power developed will be in the neighborhood of 14,500 shaft horsepower. The vessels will be built by Harland and Wolff at Belfast and the engines will be of the new double-acting, four-cycle type developed by Burmeister and Wain, for which firm Harland and Wolff are the British licensees.

These motors will have the same cylinder dimensions as the two engines to be installed in a 17,000-ton motor liner

for the Swedish Amerika Line, but instead of having six cylinders, there will be eight. Therefore, if the Harland and Wolff engines ran at the same speed as those built by Burmeister and Wain, they would normally have an output of 9,000 brake horsepower. It may be remembered, however, that in the motors now under construction for the Swedish Amerika Line's passenger boats, the air compressors are not driven directly off the engines, but that three separate compressors are to be installed in the engine room driven by a 600 horsepower Diesel engine.

In the new Royal Mail liners, a more normal system will be employed, and the air compressors—two in number—will be driven off each engine. As a result of this, combined with lower engine speed than that adopted by the Danish builders, the output of each engine will be only about 7,250 brake horsepower. The diameter will be 840 millimeters, the stroke 1,500 millimeters and the piston speed will be kept down to about 1,100 feet per minute.

PISTONS TO BE OIL COOLED

There will be a very large electrical installation as all auxiliaries are to be electrically operated. It is understood that one of the most interesting features in the design of the engines, apart from the adoption of the double acting principle, is that oil cooling will be utilized for the pistons. To the engineer who has followed Diesel engine development during the past ten years, this seems somewhat like a retrograde movement, since oil cooling was adopted many years ago and afterwards abandoned in favor of fresh water cooling in some cases, and salt water in others.

The use of lubricating oil in these large engines is the re-

The 4,400-Ton Motorship Kolsnaren

sult of some very successful trials that have been carried out on the single cylinder 1,000 horsepower unit which Burmeister and Wain built for experimental purposes. It should be remarked, however, that the oil which circulates around the piston is not actually used for lubricating. A closed circuit is maintained and the oil is utilized for no other purpose than for reducing the temperature of the piston head. It is claimed that with this arrangement the temperature can be kept down to a normal figure so as to prevent carbonization, which was one of the original troubles, and, moreover, with an entirely closed circuit the loss will be extremely small.

MANY SINGLE SCREW MOTORSHIPS

The increasing confidence which is now felt in the oil engined vessel among all classes of shipowners is reflected

in the growing number of single screw vessels of this type which are now being commissioned. There is no doubt that hitherto the employment of twin screws has been almost wholly due to the fear of unreliability, since nine ship-owners out of ten, or perhaps even a larger proportion, are greatly in favor of the installation of one engine.

A somewhat unusual single screw ship has just been completed for Alfred Holt and Company, one of the largest ship-owning concerns in Great Britain. This vessel, the *Medon*, built on the Tyne, has a deadweight capacity of 8,000 tons, is 400 feet in length and is a duplicate of several steamers owned by the same firm, so far as power and dimensions are concerned. She is fitted with a 3,000 indicated horsepower Burmeister and Wain engine, this being the biggest motor of the long stroke slow speed type that has yet been constructed, operating on the four-cycle principle. It develops

Single Screw Motorship Sally Mærsk

its power at 85 revolutions per minute whereas the normal speed for 3,000 indicated horsepower, Burmeister and Wain engines is 115 revolutions per minute.

The eight cylinders have a bore of 740 millimeters and a stroke of 1,500 millimeters. Particularly noteworthy is the arrangement for supplying the compressed air for starting and maneuvering purposes, as it is a new system which it is understood will be standardized by Burmeister and Wain.

As is well-known, in most motorships a large electrically driven maneuvering compressor is fitted. In British motor vessels of 14,000 tons with 6,000 indicated horsepower twin-screw machinery, there are two such compressors, each driven by a 180 horsepower electric motor. This is a costly plant and the new method adopted in the *Medon* is to supply the maneuvering air from the engines driving the dynamos. There are three of these sets each of 100 horsepower and the injection air compressor normally fitted is enlarged so as to give a surplus output beyond that needed for injection on the engine itself. This surplus is stored in the air reservoirs, and no auxiliary air compressor is needed. Normally, the generating sets operate in the ordinary manner, and when it is desired to charge a starting bottle, a simple change-over device is operated. This seems to mark a distinct step in the development of auxiliary equipment of motorships.

Another single screw motorship which has just been completed is the 4,400-ton *Kolsnaren* for the Transatlantic Steamship Company of Gothenburg. She is 304 feet long overall, and is propelled by a 1,600 indicated horsepower Burmeister and Wain type engine built by Gotäverken. This

also is a long stroke motor which of course was developed specially for single screw propulsion. It is interesting to note that the *Kolsnaren* is a sister ship to the *Hjelmaren* in which a two-cycle Atlas Diesel engine of the same power was fitted. Curiously enough, it is stated that the four-cycle engine occupies less engine room space than the two-cycle type fitted in the *Hjelmaren*.

A third single screw motorship completed a short time ago is the *Sally Maersk*, a 5,200-ton vessel, in which a Burmeister and Wain engine of the same power as that fitted in the *Kolsnaren* is installed. The bore and stroke are 630 and 1,300 millimeters respectively, the normal speed being 90 revolutions per minute. On trials, the *Sally Maersk* which is 331 feet long overall, and has a guaranteed speed of 10 knots, showed a fuel consumption of 4.9 tons daily. The single screw ship seems to give slightly better results than twin-screw craft, the fuel consumption being almost invariably 5 percent lower. It may be added that the *Medon* appears to be an exceptionally economical ship since her consumption works out at under 9 tons daily. This is a very good result for an 8,000-ton vessel with an average speed of approximately 11½ to 12 knots.

The Holt Line has just taken delivery of another motorship, the *Tantalus*. This is a twin-screw craft carrying about 11,000 tons deadweight, and is one of the largest of recently built motorships. Two 3,000 indicated horsepower Burmeister and Wain engines are fitted but these are of the short stroke type running at 115 revolutions per minute. The *Tantalus*, which is 477 feet long, attained a speed of about 14½ knots on trials, and it is anticipated that the fuel consumption will not exceed 20 tons daily.

Automobile Carrying Fleet Developed on Great Lakes

**Forty-One Steamships in the Trade Carry Over 250,000
Cars Per Season—Total Freight Amounts to \$5,000,000**

By Alfred C. Jackson

A NEW transportation service, with a season's revenue of over \$5,000,000, has been developed on the Great Lakes by the automobile industry and with it the city of Detroit is regaining its title as a Great Lakes port which was lost 30 years ago when the Ward Line dwindled and died. This new business is handled by a fleet of 30 freight vessels, aggregating 95,722 gross tons, together with several tramp or "casual" vessels and 11 large passenger steamers. The total premium for the marine insurance placed on the cargoes of automobiles carried in a season is based on a value of \$380,000,000.

METHOD OF LOADING

Most of the steamers used for the transportation of automobiles are provided with 'tween decks and with one or two steam winch-driven elevators which lower the cars into the hold. The speed of loading depends upon the speed of the elevator but averages about 30 cars an hour. The rate of unloading is about the same as that of loading. Side ports are generally unsuitable, as to handle all models of closed cars they must be 8 feet high which is a greater height than is permitted by the classification societies on account of the resulting weakness in the vessel's structure. Less time is required to load a cargo of automobiles than is required for many other types of cargo.

Automobiles are shipped from Detroit docks to Cleveland, Buffalo, Ashtabula, Erie, Toledo, Duluth, Milwaukee,

Chicago, Ogdensburg, Montreal, etc., and from some of these ports to other Lake ports as well. The manufacturers drive the cars to the steamship docks where they are stored in fireproof warehouses built on the piers. From the warehouses the cars are driven up an inclined runway on to the deck of the vessel whence they are lowered to the 'tween decks or hold by the elevators. When in position, the cars are placed in low speed gear with the emergency brake set and in some cases they are further secured by wheel blocks.

A list of the automobile trade fleet from Detroit, its cargo capacity per trip and the routes is as follows:

Detroit and Cleveland Navigation Company, Detroit.

Passenger boats, daily to Buffalo, 85 cars a trip.

Passenger boats, daily to Cleveland, 200 cars a trip.

Tri States Steamship Company: Cleveland, Chicago, Detroit, Milwaukee and Buffalo service, four sailings a week.

Freighter *Polynesia*, 350 cars a trip.

Freighter *Lakeland*, 310 cars a trip.

Freighter *Westland*, 240 cars a trip.

Freighter *Clifton*, 200 cars a trip.

Total: eleven hundred cars per trip.

Universal Steamship Company: Chicago-Detroit run, three sailings a week. Package freight carried from both ports as well as automobiles. Chartered steel boats.

Freighter *Spokane*, 240 cars a trip.

Lake Freighter *Polynesia*, of 5,700 Tons Deadweight, Carrying Deck Load of Automobiles. This Vessel Is Fitted with 'Tween Deck, and Elevator Can Be Seen Just Forward of After Deck House

Freighter *P. Foster*, 170 cars a trip.
Freighter *E. Oglebay*, 220 cars a trip.
Total: 630 cars a trip.

Nicholson Transit Company: Detroit, Toledo, Cleveland, Erie, Buffalo, Chicago and Milwaukee.

Steel freighter *Sultana*, 350 cars a trip.
Steel freighter *Sonora*, 350 cars a trip.
Wood freighter *Fellowcraft*, 200 cars a trip.
Wood freighter *Roumania*, 200 cars a trip.
Total: 1,100 cars a trip.

Rutland Lake Michigan Transit Company, Detroit, Ogdensburg, Chicago, Milwaukee service. Owns and will operate four steamers in the automobile and grain and package freight trade as above. Now operates three vessels and has another en route from the seacoast—the *Backbay*.

The S. S. *Burlington*, *Bennington*, *Brandon* and *Backbay* have a trip capacity of 150 cars each, or 600 cars per trip—although it is figured that they will carry only 12,000 cars a season as they have large merchandise tonnage to haul.

Great Lakes Transit Corporation: Buffalo, Erie, Cleveland, Detroit, way ports to Duluth, and from Buffalo to Chicago via Detroit, Milwaukee, etc.

Owns and operates twelve steel steamers in the automobile trade. The vessels are package freighters and carry flour on the return trips. The 12 steamers will carry 1,500 cars a trip. This firm operates three steel passenger steamers which run every three days from Detroit and carry 45 machines each trip, making a total of 1,635 cars a trip.

Crosby Line: Detroit to Milwaukee service. "This is the last line to enter the automobile carrying business.

Owns the wooden steamer *Tom Davidson*, with a trip capacity of 250 cars.

Other vessels include the *Fleetwood*, the original wooden automobile trader, 165 cars a trip, and the *Bielman*, with 260 cars a trip; also wooden steamer, and the *Tampico*, a steel ship.

The Northern Navigation Company, Detroit to Duluth, and Fort William, Port Arthur.

Three sailings per week of passenger steamers, with 50 cars each, or a total of 150 a trip.

The White Star Line, Detroit to Toledo.

Two passenger boats daily. Total, 20 cars.

Altogether, therefore, there are 41 steamers in the trade, of which only 5 are wooden vessels. Most of the lines own their own steamers and only a few charter vessels.

The trip capacity of the steamers is over 6,385 automobiles per sailing, or for the season, allowing for the carriage of package freight, etc., a total of 250,000 cars.

The revenue runs from \$10 to \$40 per car—and averages \$20 to \$25—so that a very conservative total is five million dollars freight for the season.

While the situation has brought relief to the automobile makers, and profits to the vessel owners, it has instilled real happiness in the hearts of veteran vessel men, who for years have watched with regret the stately processions of freighters move past Detroit. The vessels are now stopping at this port in increasing numbers. Detroit is again a port instead of a mail station, and the old tars are digging up their musty oil skins and beginning to stretch their sea legs.

Empress of Asia Loading Automobiles for Japan

The picture shows the Canadian Pacific liner *Empress of Asia*, loading several car loads of automobiles which she carried in her hold when she last sailed for Yokohama. Flat cars with five and six automobiles to the load came alongside the great liner. Each case weighed approximately 4,500 pounds.

Protective Coverings for Shipbuilding Purposes: Paints

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view. This is the second installment of the article on paints.

EFFORTS to produce red lead paints the pigment content of which would remain in suspension have mainly been along the lines of the addition of some inert material, such as asbestine (silicate of magnesium), to the red lead rather than attempts to produce a superior article. A number of products resulting from such efforts are on the market and they are frequently called, and may be classified as, reinforced red lead paints.

REINFORCED RED LEAD

One of these paints adopted as standard in 1918 by the War Service Committee of the Paint Industry, for general priming work on steel hulls has the following specifications:

Pigment, 65 percent.

Liquid, 36 percent.

The pigment portion shall consist of—

Red lead (not less than).....60 percent

The balance shall be silicious matter, such as aluminum silicate, magnesium silicate, silica, or a mixture thereof.

The red lead used shall contain not less than 85 percent Pb_3O_4 , the balance to be PbO .

The liquid portion shall consist of—

Pure raw linseed oil (not less than 90 percent), the balance to be combined drier and thinner. The thinner shall be turpentine.

Special requirements: The paint shall weigh not less than 16 pounds per gallon. It is intended to be used for a priming coat on steel and when applied to a smooth iron surface, it shall dry in 12 hours, without running, streaking or sagging.

During 1918 a number of well known paint manufacturers adopted the following formula for the manufacture of this kind of paint:

Pigment, 70 percent.

Liquid, 30 percent.

Pigment:

The pigment portion shall consist of not less than 80 percent red lead. The balance shall be silicious matter, such as aluminum silicate, magnesium silicate, silica or such mixtures thereof as will insure the production of a prepared red lead paint which will hold well in suspension. The red lead used shall contain not less than 85 percent Pb_3O_4 ; the balance to be PbO . The red lead is to be finely ground.

Under silicious matter $3\frac{1}{2}$ percent may be sesquioxide of iron.

Liquid:

The liquid portion shall consist of not less than 70 percent of pure raw linseed oil.

The balance of the liquid, 30 percent, shall be combined drier and thinner. Thinner will be 11 percent volatile mineral spirits.

Special Requirements:

The paint shall weigh approximately 18 pounds per gallon and is intended for general use as priming coats on steel ships and when applied to a smooth iron surface it shall dry in 12 hours under normal conditions without running, streaking or sagging.

The paint must be satisfactory in every respect, including body, freedom from objectionable settling or caking in package. Paint must also have satisfactory working qualities, hiding power, drying, color, gloss and durability.

Percentages are to be by weight unless otherwise specified.

Packages shall bear proper identification as regards certification marks.

These specifications were submitted to the Bureau of Standards who pointed out the fact that the paint contained only 10 pounds of red lead per gallon of paint, or one-half the amount in the United States Shipping Board specifications before mentioned, and stated their opinion that red lead paints are more efficient as protectors for steel in proportion to the red lead present. They also stated that they made up a paint according to the specifications and found it to be very thin. They recommended a change in the specifications for the liquid as follows:

The liquid portion shall consist of not less than 90 percent of pure raw linseed oil.

The balance of the liquid, 10 percent, shall be combined drier and thinner. The thinner may be turpentine, mineral spirits, or a mixture thereof.

A well known proprietary reinforced red lead paint has the following formula:

Pigment—57 percent. Red lead (85 percent Pb_3O_4)....80 percent

Silica and silicates.....20 percent

Vehicle—43 percent..Linseed oil 86 percent

Drier and thinner.....14 percent

Weight per gallon—14 $\frac{3}{4}$ pounds.

The general manager of a paint manufacturing company which turns out a reinforced red lead paint made up with boiled linseed oil as a vehicle told the writer he recognized it was not the paint for use on shipboard, although he had a record of very good results from the use of this paint as compared with the United States Navy standard red lead paint as an acid resisting paint and for railroad work. He realized that the marine service called for a higher proportion of pigment and a harder paint, notwithstanding their use of boiled oil for the latter purpose.

GRAPHITE

The use of natural graphite instead of asbestine with red lead produces a paint which if properly made is an improvement over the reinforced red lead paints. We may classify such a paint as a graphite paint although the pigment should be largely red lead. Graphite paint that is not made up with a large percentage of red lead and with linseed oil as the major part of the vehicle has not proved its value as a priming paint, as far as is known to the writer. A tendency with this kind of paint is to have too little pigment as, on account of the strong brown color, a very thin coat will appear to be a good coating. There is also a tendency to have the graphite too coarsely ground. The natural graphite mineral is not pure carbon and the composition of the paint will depend considerably upon the composition of the graphite. The writer believes that the following is, however, a representative analysis:

Pigment—53.4 percent Red lead (89 percent Pb_3O_4)..52.01 percent

Carbon 19.74 percent

Iron oxide 6.55 percent

Zinc oxide 2.25 percent

Silica and insoluble.....19.45 percent

Vehicle—46.6 percent Oil, mainly linseed..... 84 percent

Thinner and drier..... 16 percent

Weight 13.24 pounds per gallon.

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

This does not appear on the face of it to be an improvement over a reinforced red lead paint, but the graphite is itself a valuable pigment, as the tests referred to later show, and the principal manufacturer in this country of this kind of paint has produced a product which has been used extensively as a priming paint in the marine field with good results. This company uses a good grade of red lead and their own graphite, and the vehicle is mainly linseed oil with a small proportion of China wood oil. They claim that the graphite makes the paint more elastic than a pure red lead paint and that the China wood oil fills up the pores in the linseed oil and makes the paint more waterproof than a paint containing only linseed oil.

In the tests made by the American Society for Testing Materials artificial graphite appeared to be of little or no value as a pigment in paint designed to protect iron or steel from corrosion, and it is not to be expected that a desirable marine priming paint can be produced with all natural graphites. The graphite in the above analysis was mined in Superior, Wis.

OXIDE OF IRON

There are many paints proposed for use as priming paints which have pigments that are largely iron oxide. In actual service as priming paints they are inferior to red lead paints, and possibly the reason is the difficulty of freeing the iron oxides from soluble or injurious constituents.

Sometimes oxide-of-iron paints are made from by-products of sulphur compounds, and calcium carbonate is added to offset the evil due to the presence of the sulphur. This results in the formation of calcium sulphate, which is soluble, and possibly harmful.

One manufacturer whose paint is used extensively for structural metal work on land has added to the iron oxide chromates of lead and zinc. He states that the latter were found to be particularly valuable in resisting rust stimulation, and this appears to be substantiated by the tests referred to later on in this article.

A proprietary oxide-of-iron paint that has been considerably used as a priming paint in ship construction is said to have the following analysis:

Pigment—55 percent	Iron oxide	70 percent
	Silicious earth pigments	30 percent
Vehicle—45 percent	Raw linseed oil	50 percent
	Linseed oil, heat treated	25 percent
	Drier and volatile mineral spirits	25 percent

Another proprietary metal protective paint which is used by some shipbuilders and the pigment of which is largely Spanish Red has approximately the following analysis:

Pigment—48.0 percent	Iron oxide	56.0 percent
	Zinc oxide	10.0 percent
	Calcium sulphate	2.0 percent
	Lead sulphate	1.0 percent
	Silicates (asbestine)	24.0 percent
	Organic matter, etc.	7.0 percent
Vehicle—52.0 percent	Linseed oil	64.0 percent
	Gums	8.0 percent
	Petroleum oil	28.0 percent

Some proprietary oxide of iron paints have red lead as well as zinc oxide and other materials as a part of the pigment. Some lay great stress on a prepared linseed oil vehicle. Others do not use any linseed oil at all. An analysis of one of such paints proposed for marine service as a priming paint on steel is as follows:

Pigment—35.6 percent	Iron oxide	27.8 percent
	Red lead	24.0 percent
	Calcium sulphate	40.6 percent
	Silica	1.0 percent
	Organic matter and dye	6.6 percent
Vehicle—64.4 percent	A tung oil	resin varnish

Although the red lead in this paint by weight is almost

as large a portion of the pigment as the iron oxide, it is much less so by volume, and the calcium sulphate, as previously stated, is soluble in water. The formula as a whole looks unattractive.

About 1918 the Mare Island Navy Yard conducted experiments on paints to be used as a substitute for red lead priming paint on account of the poisonous nature of the red lead powder and the high cost of red lead and linseed oil, and met with considerable success with the following formula:

Venetian red in oil	2½ pounds
Metallic brown in oil	2½ pounds
White zinc oxide in oil	1 pound
Drier	½ gallon
Mixing oil (China wood)	⅝ gallon

The writer has not heard of any recent developments along this line.

ELATERITE

A paint made from Elaterite which has been referred to under the preceding article on "Bituminous Compositions," is proposed by its makers as a priming paint. There is no question of the value of this paint as a priming paint on inside work, where subsequent coats can be of the same material, but the writer has had no experience with it as a priming paint under other paints, and it is questionable if other paints will adhere well to it and will not be softened or discolored by it.

WHITE ZINC

This is a good pigment theoretically but it scales off of steel work.

TESTS

In 1908 the American Society for Testing Materials set up steel panels at Atlantic City which were coated with about fifty different kinds of paint. The plates had previously been cleaned by pickling. The pigments were purchased in the open market, and mixed into a vehicle consisting of $\frac{2}{3}$ gallon of raw linseed oil and $\frac{1}{3}$ gallon of boiled linseed oil. They were made up in consistencies that would allow of a uniform application at the rate of 900 square feet to the gallon, per coat. Three coats were applied. They were inspected annually in 1910 to 1914 inclusive by five inspectors, including Dr. P. H. Walker and Dr. H. A. Gardner, and graded from zero to 10 by each one, for the condition of the plate as regards corrosion and for the condition of the coating. The following table shows the average of the individual gradings at the 1914 inspection for the ten best paints as regards protection of the steel from corrosion, and for several others which are of particular interest in a consideration of priming paints on ship steel:

	Pounds Pigment Per Gallon Oil	Weight of Paint Per Gallon	Average Rating
1. Basic lead chromate	20.49	...	7.5
2. Sublimed blue lead	19.17	20.17	6.0
3. Carbon black (99 percent carbon) and nat. barytes	1.39 } 10.03 }	13.92	5.0
4. Chrome green, blue shade	13.32	16.17	5.0
5. Willow charcoal	4.47	9.00	4.5
6. Red lead	26.10	24.42	4.0
7. Natural graphite	7.80	11.42	4.0
8. Zinc chromate	10.71	13.08	4.0
9. Zinc and lead chromate	14.28	16.0	4.0
10. Black iron oxide	15.00	16.0	4.0
11. Orange mineral	26.91	24.75	3.0
12. Metallic brown	9.51	12.5	3.0
13. Bright red iron oxide	15.78	17.08	2.5
14. Venetian red	9.30	12.67	1.5
15. Zinc oxide	16.68	17.67	0 (arbitrary)
16. Asbestine	8.25	11.5	0 (arbitrary)
17. Artificial graphite (90 percent carbon)	6.63	10.5	0 (actual)

Barytes is barium sulphate and was added to give sufficient

body to the paint. The chrome green is lead chromate, lead sulphate, white lead and Chinese blue. The metallic brown is made by roasting iron ore. The bright red iron oxide is 98 percent oxide of iron (copperas red). Venetian red is made by calcining a mixture of copperas and terra alba. The other pigments have been explained or require no explanation.

Paints 3, 13 and 15 were very heavy and required to be reduced by the addition of turpentine.

Although red lead and orange mineral are pretty well down on the list it will be noted that the weight of pigment per gallon of oil is not what it should be for best results, and the amount of true red lead, Pb_3O_4 , is not stated. This test does not take into consideration the fitness of the paint as a base for other paints, the abrasive wear resisting properties of the paint, and other factors entering into the selection of a priming paint. The results are, however, of considerable interest.

The American Society for Testing Materials has also conducted tests on 19 paints on a railroad bridge at Havre de Grace, Md. The steel was coated with three coats which differed somewhat from each other along the lines of the actual use of the different kinds of paint. They were rated according to class, there being a number of classes. The only paint to retain the first class for the entire period of seven and one-half years was a pure red lead and linseed oil paint in which the red lead was 95.9 percent Pb_3O_4 . The second best paint was also a red lead and linseed oil paint, but in this case the red lead was 88.5 percent Pb_3O_4 . It remained in the first class for five years and was in the second class for the remaining two and one-half years.

GENERAL

A number of the foregoing paints are proposed as priming paints not because they are equal to the standard red lead and oil but because they can be sold at a lower price and are attractive on that account. The priming coat of paint on steel is, however, one of the worst items on which to try to save money, and the reader will probably realize this from what has been written. Where circumstances appear to merit a departure from the old stand-by, red lead, and a trial of some other make of paint, the analysis and other information here given may prove to be a guide to the probable value of the proposed paint and the result to be expected from it. It must be remembered, however, that some proprietary paints of about the same analysis may differ widely in value.

PROTECTION OF WOOD

The priming paint for the protection of wood and similar absorbent and non-corrosive materials is not so important a part of the protective coating as priming paint on steel and iron and its functions are not so varied. Its principal requirement is that it shall form a good backing and binder for the second or heavy coat of paint.

Wood absorbs the vehicle and therefore the priming paint has to be relatively thin or the oil will all go into it and leave the pigment as a dry non-adhesive coating, not suitable as a binder for the next coat. Pitchy spots do not so readily absorb the oil and for this reason as well as to reduce costs a considerable amount of turpentine is generally used, which has a solvent action on the pitch and makes the absorption more uniform. The pigment part of the priming paint is generally the same as that of the subsequent coats, except for the addition of color to the latter in some cases.

The wood should be thoroughly dry before applying the paint.

WHITE LEAD AND ZINC OXIDE

White lead either as basic sulphate or basic carbonate together with zinc oxide has been found to be the best all around pigment combination for priming coats on wood. The oil should be pure linseed oil and the entire vehicle

is the vehicle of succeeding coats, except that it is thinned with turpentine to the amount necessary to get good penetration. About 40 percent of oil and 60 percent of turpentine is a standard proportion. The turpentine, being volatile, soon evaporates. For the highest grade of interior work the surfaces are first shellacked and then painted with priming paint, well brushed into the wood, after which they are sandpapered. The further treatment will be dealt with in another article.

The old fashioned practice was to use all linseed oil and less pigment and that is probably well worth the extra cost on outside work. One old formula of this nature is as follows, the oil being boiled for outside work and raw for inside work:

White lead	7	pounds
Red lead	$\frac{1}{4}$	pound
Linseed oil	3	pints
Drier	2	ounces

The white paint adopted as standard by the United States Shipping Board Emergency Fleet Corporation has the following specifications, resulting from the work of Dr. P. H. Walker and Dr. H. A. Gardner:

WHITE PAINT

(a) The paint desired shall have a clear white color. The pigment shall have the following compositions:

Zinc oxide—not less than 25 percent nor more than 50 percent.

The remainder may be either basic sulphate—white lead or basic carbonate—white lead, or a combination of the two.

(b) If desired, there may be substituted for a part of the lead pigments either magnesium silicate, silica, barium sulphate, or calcium carbonate, or mixtures of these pigments, in amounts not aggregating more than 15 percent of the total pigment. In any event the pigment portion of the paint shall contain not less than 85 percent of total lead and zinc pigment.

(c) A trace of blue (ultramarine) may be added to make a clear white color.

(d) The vehicle shall consist of pure linseed oil, liquid drier and volatile thinner, which may be either turpentine or mineral spirits, or a mixture of these. No resin shall be present. The total volatile thinner, including that contained in the liquid drier, shall not exceed 10 percent of the total vehicle.

(e) The paint shall contain not less than 64 percent by weight of pigment and weigh not less than $15\frac{1}{4}$ pounds per gallon. The paint must be satisfactory in every respect, including body, freedom from objectionable settling or caking in can. The paint must have satisfactory working qualities, hiding power, fineness, drying, color, gloss and durability.

(f) Bidders must submit exact composition of paint they propose to furnish. Such formulas must fall within the limits prescribed above.

The inside white of the United States Navy Department, which is used for priming coats when the finish is white, often without thinning, has the same ingredients, but the white lead and zinc oxide are each 50 percent of the pigment, the pigment weight is a greater percent of the total and a gallon of the paint weighs 18 pounds. The proportions per gallon are as follows:

White lead in oil	7	pounds
Zinc oxide in oil (American)	7	pounds
Raw linseed oil	$7\frac{2}{3}$	gills
Mineral spirits	$8\frac{1}{6}$	gills
Drier	$1\frac{1}{2}$	gills
Ultramarine blue, in oil	$1\frac{1}{2}$	ounces

Where the finish is gray the Navy Department uses the same paint for priming coats as finishing coats also. It has the following formula, for one gallon:

Barium sulphate, in oil	3	pounds $11\frac{1}{2}$ ounces
Zinc oxide, in oil	4	pounds, $7\frac{1}{2}$ ounces
Lampblack, in oil	1.4	ounces, about
Linseed oil, raw	3.8	pints
Mineral spirits	$\frac{1}{2}$	gill
Drier	5	gills
Weight per gallon	15	pounds; 8 ounces

A number of the shipyards and other marine users of priming paints mix them up themselves in order to be sure of results. One shipyard uses pure white lead only as the pigment, and a vehicle that is half linseed oil and half turpentine, with a small quantity of Japan drier.

There are a number of proprietary priming paints on the market and one well known one has the following analysis:

Pigment—65.7 percent...	Lithopone	93.0 percent
	Lead sulphate.....	6.2 percent
	Silicon dioxide	.8 percent
Vehicle—34.3 percent....	Linseed oil	35.3 percent
	Mineral spirits	64.7 percent

Lithopone is a somewhat variable mixture of zinc sulphide, barium sulphate, zinc oxide and zinc carbonate. It should contain not less than 26 percent of zinc sulphide.

RED LEAD

Red lead is considerably used as a priming paint for wood in some localities and appears to be particularly valuable

where the wood is full of pitch and will not take paint well, as it is less likely to soften and blister over pitchy spots. Its color is against it if the finish is to be white, but it is not likely to affect grays or other tints. A mixture of half red lead and half white lead may be used even if the finish is white.

Dr. A. H. Sabin recommends the following formula which makes 6 gallons of paint, as priming paint for cypress, yellow pine and similar woods:

100 pounds paste red lead
1¾ gallons raw linseed oil
1¾ gallons turpentine
¼ gallon drier.

He also recommends the following which makes 7½ gallons of paint, for white pine, poplar and similar woods:

100 pounds paste red lead
4½ gallons raw linseed oil
¾ gallon turpentine
¾ gallon drier

Marine Underwriting Conditions Unsatisfactory

Annual Report of United States Salvage Association Discloses Difficulties—Syndicates "B" and "C" Make Gratifying Returns

By "Bordereaux"

DISTRIBUTION is now being made of the report of the annual meeting of the United States Salvage Association for the year 1922, just from the press. It is irrefutable evidence of the success of this great undertaking and stamps it as a factor of prime importance in the shipping life of the country. Manager Lawrence J. Brengle, of the association, reviewed the work of last year in considerable detail. He pointed out that at present underwriting conditions are far from satisfactory, due to the low value of tonnage and the complete demoralization of the foreign insurance market, "which has been willing to accept risks at rates which leave no possible chance for profit owing to the fact that the cost of repairs is still at a high level, being estimated at least 50 percent in excess of pre-war prices."

The underwriting exhibits incorporated in the report give gratifying evidence of Syndicate "B" having shown a profit for 1920 and 1921 of \$484,843.96, or 71.57 percent, after taking into consideration all expenses, including paid and estimated losses, as well as expenses of operation, which latter amount to but 3.67 percent.

The real activity of the Syndicates is shown by the business done in Syndicate "C," which has endeavored to retain at fair rates an interest in those fleets in which it was felt a reasonable profit could be made, and decline fleets on which the foreign market quoted rates which would apparently exclude any hope of profit. The profits on the 1920-1921 business may now be considered as earned, the account showing a credit balance of \$1,853,810.25, equal to 34.27 percent, after deducting all expenses including paid and estimated losses, as well as expenses of operation, which latter amount to but 1.68 percent. While the 1922 account does not at present show a profit it must be borne in mind that that year has not yet run off and that another year at least must go by before any definite figure can be known.

Salvage work of considerable extent and universal success was carried on by the Salvage Association during the past year. Important connections have been made all over the world, and facilities for useful service have been steadily increased.

Hendon Chubb, chairman of the underwriting committee of the American Marine Insurance Syndicates, in a verbal report at the meeting, expressed his views on the present status of hull underwriting in the following terms:

"The present situation in hull underwriting is indeed a very difficult one. It has been brought about by two factors: The owner has been compelled, on account of shipping conditions in general, to reduce his overhead to an absolute minimum, while, due to the increase in underwriting facilities, there has been a disposition on the part of some underwriters to grant reductions in rates and values in order to maintain or increase their premium income account.

"The general trend of the market can be appreciated by recalling the present terms on tank steamers. A well known fleet was originally placed at a 5 percent rate; the next year it was renewed at the same rate, to return 1 percent, if confined to Eastport, Demerara, and, as the vessels always traded within these limits, this was in reality a reduction in rate. The fleet is now done at 3½ percent and the values under which the individual vessels are insured have been reduced proportionately. Its record, as far as we have been able to ascertain, does not warrant this rating."

Africa Rejects Certificates

IN order to make a marine insurance certificate acceptable in South Africa it is well to have the contract contain the words, "documents to be accompanied by an insurance policy or certificate of insurance." In a recent suit at Cape Town, at which Justice Benjamin presided, the law of the Union of South Africa was declared to be the one under which the merits of the case should be construed, and not the law of the United States despite the fact that the bills of exchange had been drawn by a firm of the latter country. The drafts were each accompanied by what was known as a "through bill of lading" and a certificate of insurance. The "through bill of lading" purported to be a receipt at Leavenworth, Kansas, for carriage to Cape Town by way of certain American lines of railway to New York, and thence by the American-African Line to the port of destination, Cape Town. In his Lordship's opinion such a document could not be regarded as a bill of lading under the law of the Cape Town Province. It had been decided in England

that a bill of lading, from the earliest times, was a document which acknowledged shipment aboard a particular ship.

As regards the certificates, his Lordship observed that "they were merely certificates and not policies." These certificates, he said, had been held in England not to be policies of insurance, and as justifying the repudiation of the contract in which they had been tendered by the seller. "Both were recognized in the Union by custom. But the evidence on this point was not sufficient to prove 'custom,' which, as had been laid down by the Appellate Division, must be reasonable, immemorial and certain."

Hull Underwriters Complain

INJUSTICE is charged by certain English hull underwriters in that, despite their being charged half additional premiums on total loss reinsurances when vessels have broken trading warranties, they are nevertheless refused any return on the total loss reinsurance when the original "all risks" policy has paid one for special trading. Discussing this point an authoritative critic observes: "Had the insurance been based on the assumption that the special trade would be the one the vessel was employed in, the original rate would have been reduced by the amount of the return, and the warranties would have limited the vessel to the specific trade. Had she gone outside that trade, an additional premium would have been paid, in which the reinsuring underwriters would have participated. This would have achieved the same result as the giving of wider warranties and leaving it open to the owner to collect a return for special trade, except that the reinsuring underwriter gets an additional premium in the former case, but makes no return in the latter."

Intercoastal Coverage

THERE has been a considerable profit to underwriters in the large water-movement of freight to the East and West coasts of this country; and there have been comparatively few disasters. Much of this intercoastal trade is insured by the shippers with the carriers under the bill of lading, the carriers, in turn, declaring such insurance to their open cargo underwriters. On account of the unusual freedom from losses there has been a softening tendency in the rates for this class of business for some time past, and shippers have had no difficulty in obtaining quotations much lower than the bill of lading. Besides that, the shipper with an open policy secures a broader cover than that granted under a bill of lading, as the open policy will unquestionably cover from warehouse to warehouse, whereas the bill of lading insurance attaches and ceases at the port. It is rumored that discounts are being granted under the bill of lading insurance, and it is possible that some such method is being used by the bill of lading underwriters to meet the market tendency toward lower rates. There have been several losses of late, and should their number increase they may exert an upward tendency on the rate.

Select Dependable Carriers

TOO much importance can not be placed upon the necessity for shippers to make choice of carriers that are financially sound before entrusting business to them. There are so many dependable lines in the market that merchants have only themselves to blame if they become involved in expense and embarrassment through having been attracted to unreliable carriers by the lure of a cheapened rate. Illustrations of this necessity have of late been frequent. Recently the *Capitaine Faure*, of the Fulton Steamship Company, served to point the moral. This vessel lay at New York loaded for the Far East, but her owners found

themselves without sufficient money to forward her. The consequence was that her cargo had to be discharged, and the shippers concerned were obliged to form a committee to make arrangements for forwarding their merchandise by some other steamer. At that point in the proceedings, the case stood as an abandoned voyage, due to financial causes. There was, consequently, no liability on the part of the underwriters; but there would have been had the vessel gotten under way.

Near East Insurance

THE settlement of the Greco-Turk dispute had an important bearing on commercial routes in the Near East. The British are discussing the completion of their proposed rail line from Aleppo to Bagdad, and it is probable that Russia will proceed with the construction of the railroad through Persia to Baluchistan. Before the war, a large part of goods coming out of Northern Persia were shipped by rail to Tiflis, and thence via the Black Sea to Constantinople for transshipment to the United States. Since the war began, these shipments had to be made by way of Bagdad and Basra. As but few ocean steamers load at Basra, a transshipment is frequently made at Karachi or Bombay, thus entailing extra handling and the usual delays and hazards consequent upon transshipment. The principal shipments from Northern Persia consist of rugs, and the long caravan trip, with the possibility of fresh water damage on the voyage down the Tigris, are responsible for much more damage than in all likelihood would occur on the shorter route via Tiflis or Trebizond.

American Laws and British Cover

THE United States Circuit Court of Appeals has rendered a decision to the effect that insurance policies issued by British companies on American ships operated in or near American waters are subject to the laws of this country and not to those of England. The case was on appeal by the Marine Insurance Company, the Century, and the Employers' Liability, all of England, from the decision of the district court at Baltimore, Md. It was decided by the lower court that these companies were liable in American dollars, not in English pounds, to J. Craig McLanahan, ancillary receiver of the West India Sugar Corporation and the Equitable Trust Company, for the amount of the policies on the barge *Detroit* which was lost in a collision in the Mississippi river on August 27, 1919. At the time of the issuance of the policies a pound sterling was worth \$4.77 in American money, but when the collision occurred the rate of exchange had fallen to \$3.37. The insurance companies sought to pay the claim at the lower rate, although it was stated in the policies that a pound would be accepted at the exchange rate of \$4.75. In his opinion Judge McClintic held that the court was bound by the decision of the English Court of Appeals and the House of Lords in an identical case.

Bad Stowage Voids Policy

IMPROPER stowage of cargo constitutes negligent navigation and creates an unnecessary increase of the risk, both at common law and under a fair reading of the terms of the policy; and no recovery can be had in consequence. Such was the recent finding of the New York Court of Appeals, in affirming the judgment of the Appellate Division, Third Department, in the case of *William N. Cary and Edward L. Gailor v. the Home Insurance Company*, 235 N. Y., 296; 139 N. E., 274. In the course of the Court's sum-up citation was made of the case of *Leitch v. Atlantic Mutual Insurance Company*, wherein it was held that "one

of the conditions implied by law in case of an insurance upon cargo is that it shall be stowed in a safe and proper manner, and in the usual and customary place for the carriage of goods of the description insured, and any breach of this warranty by which the risk is varied and the perils insured against increased vitiates the policy." It was also held that it is the duty of the insured to keep the vessel seaworthy during the risk, if practicable so to do. As regards seaworthiness the Court observed that "a ship is seaworthy when reasonably fit in all respects to encounter the ordinary perils of the sea incident to the adventure insured."

Repairing One of the Largest Steel Castings in Existence

ONE of the largest Thermit welds which the Metal and Thermit Corporation has ever been called upon to supervise was recently completed on a rudder post casting for the U. S. S. *Saratoga*. This vessel was formerly under construction as a battle cruiser, but under the terms of the disarmament conference was ordered by the Government to be completed as an aeroplane carrier. The casting itself weighed 56 tons and the width of the casting at the fracture was 13 feet 6 inches. The crack extended through this entire part in an irregular line; its length, therefore, was considerably greater than the dimensions given above. The thickness of the section where the fracture occurred averaged about 3 inches, except where it passed through several reinforcing ribs about 15 inches high and through projections of about 26 inches at the top and bottom.

On the recommendation of the Penn Seaboard Steel Corporation, the Government decided to authorize a Thermit

Fig. 1.—Rudder Post Laid on Its Side on Foundations in Deep Pit Preparatory to Welding

weld rather than incur the expense of making a new casting which would require about 2 months to complete and would cost in the neighborhood of \$20,000. The welding, therefore, was undertaken at the shops of the Penn Seaboard Steel Corporation at Chester, Pa.

In making preparations for welding, the rudder post casting was laid on its side in a deep pit, so as to obtain proper clearance from the overhead crane, also in order to secure greater accessibility to the upper parts during welding. In this position the break extended in a vertical plane, thus allowing the liquid steel to be poured from one crucible and permitting this steel to be gated into the mold at several points so as to secure a uniform flow of superheated Thermit metal by all parts of the fracture.

To support the casting during the welding operation a substantial foundation was built underneath it. Under the large end, a bed plate 12 feet long by 6 feet wide was laid on 12 inch by 12 inch timbers. Two layers of 12 inch I-beams were placed on the bed plate and on these I-beams, 4 inch diameter bosses on stools in turn were placed directly supporting the casting. A small bed plate 12 feet by 3 feet was placed under the small end with five layers of I-beams above the bed plate supporting this end.

The fractured end was braced vertically by means of two angles bolted to channels clamped to the lower gudgeon as shown in Fig. 1.

The gap cut out at the fracture averaged about $\frac{3}{4}$ inch wide. A total of 80 pounds of wax was used for the pattern.

Fig. 2.—Gap Cut Out at Fracture Fig. 3.—Completed Weld

The width of the collar averaged about $4\frac{1}{2}$ inches. The wax pattern took two men twelve hours to apply.

The exceptional length of the fracture necessitated the construction of a mold box approximately 16 feet 6 inches high by 4 feet wide by 4 feet 9 inches deep. One hundred pounds of molding material were needed to fill up the mold box. Three days were required to construct the mold box and three more days to ram it.

Preheating was accomplished with seven preheating tanks including five single burner and two double burner tanks. One hundred and seventy-five gallons of kerosene were consumed in the preheating, which was started at 4 A. M. on one day and finished at 6 P. M. the same day, making an elapsed time of 14 hours.

One thousand eight hundred pounds of Thermit in one extra large crucible were used for the reaction. The weld was allowed two days to cool off gradually. Fig. 3 shows the weld with all excess metal removed.

The total length of time consumed in the welding was 15 days, extending from the time when the casting was placed in position ready for cutting out the fracture until after the mold was stripped. This period included two week-ends when no work was done on Sundays and Saturday afternoons. The repair was made by two helpers of the Metal and Thermit Corporation assisted by two helpers from the steel plant, also a man for handling the acetylene torch for cutting out the fracture and cutting the mold box sheets.

THE ATLANTIC COAST SHIPBUILDERS' ASSOCIATION has removed its offices from 1701 to 1600 Walnut Street, Philadelphia, Pa.

DOUGLAS FIR IN BRITISH WARSHIPS.—In one of the two large battleships now building for the British Navy, Douglas fir has replaced teak, according to advices received by the Department of Commerce.

New Shipping Board Wage Scale

AFTER several conferences between the representatives of the United States Shipping Board and representatives of the associations and unions of licensed deck officers, marine engineers and cooks and stewards with reference to wages and conditions on Shipping Board vessels, and after thorough investigation by the board the increases in ship wages as set forth below became effective on July 1.

In considering the matter due weight had to be given to the cost of living, the supply and demand of American labor and the maintaining of such wages and working conditions as would make for stabilization, efficiency and economy. The working out of these things in conference is in line with the established policy of the board of collective bargaining and the recognition of legitimate organizations concerned with ship personnel.

A healthy morale and satisfied and efficient crews to man and care for the ships is necessary. The co-operation and best efforts of marine labor is looked for in helping to establish permanently an American merchant marine on the seas.

Fuel Saving Devices for Marine Boilers

ADVICES from George Nicolas Ifft, American Consul, Bergen, Norway, state that Anders Strommen, a Trondhjem marine engineer, has invented and applied for American patents on two devices for obtaining more economical utilization of combustibles under marine boilers. The inventions consist of devices for use in connection with boilers as at present installed in steamships, one by the mounting of an auxiliary fire bridge at a certain distance in front of the old fire bridge, covering the part of the grate between the fire bridges with brick work or sheet metal and supplying combustion air in an upwardly directed current through openings in a horizontal covering plate extending rearwards from the top of the old fire bridge. Practical experiments have proved that it is possible by the simultaneous application of such arrangements to obtain a very considerable improvement in the economy of the boilers.

A second device, with the same end in view, consists of mounting the fire bridge a considerable distance in front of the rear end of the fire tube, whereby the grate surface is shortened and at the same time the rear part of the fire tube is partially shut off by means of a baffle wall extending downwards from the top of the fire tube wall to within a certain distance of the bottom thereof, by which means the combustion products are deflected downwards before leaving the fire tube.

These improved arrangements do not necessitate changes in the boilers and may be applied on any boiler. The inventor claims that, in actual tests, he has secured results from 20 tons of coal equivalent to those secured from 31 tons without his device; in another case from 10 tons results equivalent to 15 tons without his device and in a third, from 15 tons, results equivalent to 19 tons without his device, the tests being made with the same kind of coal and under exactly similar conditions.

Todd School for Firemen

FREE courses of instruction for engineers and firemen in the safe and economical burning of fuel oil will be given by the Todd Shipyards Corporation at its manufacturing plant 742 East Twelfth street, New York City.

The courses will commence on August 1 and have been arranged by the Todd engineers because of the many careless and inefficient firemen working on oil burning vessels.

A few days' instruction by expert engineers, it is believed, will stimulate the interest of the men in their work and the additional knowledge they obtain will enable them to reduce the consumption of oil and thus increase the efficiency of the ships on which they work.

The courses will be along strictly practical lines and the time needed to pass an examination and secure a certificate will, of course, depend entirely on the ability of the student firemen. The instruction will include:

- Maintaining a steady temperature and pressure on the oil.
- Regulation of the air supply.
- Judging conditions by the appearance of the flame.
- How to clean strainers.
- How to light burners.
- When to clean burners.
- How to correct the little troubles that occur in the average fireroom.

Shipowners are invited to enroll their engineers and firemen.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Basic Design Problem

Q. (1,202).—I have carried out the course of procedure which you advocate in the June issue of MARINE ENGINEERING AND SHIPPING AGE, applying it to the tunnel stern vessel in the issue of April, 1921.

In preliminary calculations the value of

S corresponding to $\frac{2LAB}{H}$ is $S = 0.18$

Type of vessel—3
(ehp/EHP) $g =$
Fig. 8 v/V (type 3)
Value of v/V in article
These values I find in the upper part of Fig. 8 for $S = .19$ labeled cavitating thrusts type 2.

	0.3	0.4	0.5	0.6	0.7
Beyond curve	.666	.683	.703		
	.652	.714	.771	.822	.869

Can it be that we are using two different charts, or that the captions on the charts are deceiving?

A. (1,202).—I am afraid the difference in your readings and mine can not be charged up to misleading captions, but rather to a mistake on my part in taking values of v/V from the Type 2 instead of from the Type 1 and 3 set of lines.

Since Fig. 8 was made a new chart was gotten out by Admiral Dyson separating entirely the Type 1 and 3 from the Type 2 cavitating lines, thus permitting v/V readings down to ehp/EHP = 0 for all types of vessels.

Relative Values of Frictional and Residuary Resistance

Q. (1,206).—Please give me an idea of the relative values of frictional and residuary resistance in ships of several types.

A. (1,206).—The following data taken from page 202 Shipbuilding Cyclopaedia, Edition 1920, may be considered as representative of the results obtained in modern ships:

Type of Ship	Percentage of	
	Frictional Resistance	Residual Resistance
Destroyer	41	59
Light cruiser	50	50
Battle cruiser	59	41
Battleship	63	37
Troop transport	69	31
Fleet oiler	70	30
Cargo vessel	75	25

Passenger Capacity of Small Boat

Q. (1,205).—How many passengers may I carry on the deck of a 100-foot boat of good stability and freeboard and displacing in service condition from 70 to 80 tons without passengers?

A. (1,205).—The greatest danger in carrying passengers, particularly in a comparatively small boat, such as that described, is the possibility of their suddenly crowding to the rail and thus creating a large listing moment. To guard against serious results from this a large value of the metacentric height is desirable and a deck arrangement such as to restrain or hinder the transference of numbers of people from one side of the boat to another. Permanent ballast may be taken aboard to increase the metacentric height, if necessary.

If the boat was originally designed for passenger service, her metacentric height may be from 2 to 3 feet. Such a boat might safely carry 150 to 200 persons under ordinary river or harbor conditions. However, if the boat were not designed for passenger service and has but a small metacentric height—say one foot or fifteen inches, while she may have been very satisfactory in the service for which intended, she could perhaps carry with safety no more than 50 or 75 passengers, possibly even less.

Such a question can best be answered after a careful investigation of all the plans and stability data.

Salt Water Unsuitable for Boiler Feed

Q. (1,207).—Is it possible to keep the scale and salt out of a boiler carrying 160 pounds pressure, if you use salt water for feed? If so, how?
H. E. McF.

A. (1,207).—The writer knows of no practical means of keeping the scale and salt out of a boiler while using salt water for feed.

If salt water could be used as boiler feed without deleterious effects, the design and construction of marine steam machinery would be materially simplified.

Book on Anchors and Chain Cables

Q. (1,208).—Please give us the name of a book in which useful information regarding anchors and chain cables is given.

A. (1,208).—"Modern Seamanship" by Admiral Austin M. Knight, published by D. Van Nostrand Company, New York City, includes a valuable chapter on ground tackle. This chapter treats of types of anchors, old-fashioned and patent anchors, chain cables, details of cables, manufacture of cables, stowing, overhauling and make-up of cable, weight and strength of chain, windlasses, details of ground tackle, letting-go anchor, anchoring in squadron, anchoring in deep water, weighing, stowing of anchors, foul anchors, anchoring by the stern, riding at single anchor, advantage of long scope, dragging, mooring, advantages and disadvantages of mooring, clear and foul hawse, mooring swivel, tending ship, etc.

Materials for Anchors and Chain

Q. (1,209).—What kind of iron is suitable for anchors and chain making and what method of forging is particularly needed?

A. (1,209).—At the present time for all chain of two inches and up the United States Navy is adopting cast steel except for shackles and swivels which are to be drop-forged of a special grade of steel having a high tensile and elastic strength combined with good ductility.

Cast steel chain has also been approved by the British and American Lloyd's and is coming into use in the merchant service.

Until very recently, however, all chain cables for ships have been made of wrought iron. This material has proven suitable through years of service and is only being replaced by cast steel because cast steel chain has shown 40 percent greater strength than the best wrought iron and because cast links are more uniform in size than the forged links.

Navy Department specifications for chain cable may be

secured upon application to the Bureau of Supplies and Accounts, Navy Department, Washington, D. C.

Wrought chain for naval use is manufactured at the Boston Navy Yard. Information relative to the methods and processes of its manufacture should be obtainable therefrom.

Measurements for "Full" Displacement

Q. (1,211).—In obtaining the various coefficients, does "full" mean to the greatest outside dimension of immersed plates, or does it mean the distance to the mean thickness?

A. (1,211).—When the final calculation for displacement is made the readings may be taken either from a body plan drawn to the mean thickness of plating or from a molded body plan. In the latter case the displacement of the shell plating is estimated as an appendage and added to that of the molded hull. By either method the displacement to the mean or average thickness of the plating is obtained. Therefore, it appears logical to measure dimensions to the mean thickness of plating when calculating the value of the block coefficient for "full" displacement. However, the error introduced by using the dimensions to the outer surface of the outer strakes probably would be less than that of a good displacement calculation itself. Since coefficients are generally used for purposes of comparison the important thing is to adopt a reasonable practice and follow it consistently.

Length for "Full" Coefficient

Q. (1,212).—How is the "full" coefficient obtained, where the rudder, rudder post, propeller, etc., are included in the displacement? What length is used?

A. (1,212).—The rudder, rudder post, propellers, struts or bossing, bilge keels, etc., are usually considered appendages and their displacements are added to that of the hull proper. The augmented or "full" displacement thus obtained is used with the dimensions measured to the mean thickness of the plating. The term "full" coefficient then implies that the appendages have been considered. Theoretically the length should be taken from forward side of stem to after side of propeller or rudder post. However, no serious error (from the practical standpoint) would be introduced by using the molded length as above defined. As the coefficients of form relate essentially to the underbody proper, the inclusion of the appendages in the volume from which their values are figured is somewhat inconsistent though it is regularly done for purposes of convenience.

NEW BOOKS

Marine Directory

DIRECTORY OF SHIPOWNERS, SHIPBUILDERS AND MARINE ENGINEERS. Size, 5½ by 8½ inches. Pages, 728. The Directory Publishing Company, Limited, London, 1923.

We have just received the 1923 edition of the "Directory of Shipowners, Shipbuilders and Marine Engineers." This book, which is published annually, contains a list of the principal shipowners of the world with the addresses of their head and branch offices, the names of their ships and the names of their principal executives. It also contains a list of the shipbuilding companies with the names of their executives. This is followed by a list of consulting naval architects and marine engineers and also a list of trade organizations.

The Dock and Harbor Authority, London, has published a "Dock and Harbor Authorities' Directory" containing a list of the dock and harbor authorities throughout the world and of their principal officials.

LETTERS TO THE EDITOR

Cost of Ship Repairs

"Economy in Ship Repairs" by Mr. Robert Morell, and "Efficient Repair Methods Adopted by the United States Shipping Board" by Captain Gatewood, are two very interesting articles contributed by worthy students of their subjects. They give all that may be said from the operators' viewpoint, to whom cost of repairs represents at least 25 percent of their fixed charges. To cover the subject for the benefit of all concerned, it seems necessary to consider the repair plants, to whom cost of repairs represents 100 percent of their income. Unfortunately, successful managers of repair plants are too busy doing things to write about it, and in other cases the subject may be exceedingly painful. Having had charge of this all-important work in repair plants, as well as serving the owners in the capacity of consulting engineer on repairs, some facts may be of interest.

Economy in repairs should be studied and the high cost of repairs carefully diagnosed. Take the average shipowner; for a starter the owner personally attends to this all-important feature, but as his business grows and there is more money coming in from operation requiring his time, he spends less time and consequently more money on repairs. Rising cost of repairs causes him to make his best captain or his best chief engineer (sometimes both) remain ashore to enter the field of attending repairs. These good men, high class in their life's work as captain and chief engineer, respectively, immediately become involved in work far beyond their capacity—work that involves the expenditure of money, and they are pitted against the business end of a repair plant. It is almost unnecessary to dwell upon what happens.

The cost of a job may be known to the plant manager, but never to such an agent of the owner! The owner, therefore, gets a conglomeration of cost figures of jobs on his vessels, that would, if he could get the facts, cause a quick change to other means of attending this all-important end of his business.

There is no mystery in repair costs when one has had years of experience in costs from actual attention within the repair plant, but to expect a competent captain, or engineer, to step ashore and deal in a business that is so intricate as the repairing of a vessel, and report intelligently to its owner, is to expect something unattainable.

No owner objects to paying for work well done, or allowing a reasonable profit to be made by the repair plant, but the repair plant, forced to deal through such agencies, must protect these men in their mistakes, and both are guilty, therefore, of fooling the owner in the cost of such work. Both have good alibis. For example:

The owners' agent, having a ship repaired, overlooks essential features not included in the specifications or covered by one of those elegant and eloquent general clauses—naturally an *extra* is imminent.

God forbid any *extras*! The owners' agent is frightened into almost any method to avoid them. The repair man is asked to slip these extras in somewhere, on the next job, if necessary, thereby spoiling the opportunity of getting the real cost of any repair work on the vessel for the rest of its natural life. Neither the owners' representative nor the repair plant can report real facts to the owners for obvious reasons.

From years of experience I know wherein the cost of repairs from bills rendered has absolutely no relation to the real cost. Strange as it may seem, the cost of repairs is sometimes unknown even to the manager of the repair plant, so that the subject becomes exceedingly difficult to analyze.

Ships are as different as people and the cost of doing the

same job on different ships may in nowise be a true cost of that particular job, as there are so many contingencies that may, or may not, obtain. The best method requires fair dealing between the owners and repair plants and to my mind the owner who handles his repairs on the "live and let live" principle gets more for his dollar spent, and pays less for work done, than the "hard boiled" owner seeking to hook the repair plant on a low bid.

"Competition is the life of trade," but when competition places so valued a piece of property as a *ship* in incompetent hands, or in competent hands at too low a price, both of which comes from misguided competition, the trade becomes contaminated with a disease.

The disease may be cured!

Repair plants are as necessary as hospitals, and should be respected and encouraged as such. The prevailing attitude against all repair plants that classes the good, bad and indifferent plants and the poor, incompetent and irresponsible contractors in the same category should be eliminated.

Shipowners are operating ships to make money—they compete for cargoes on known costs of operation, so far as crew, food, fuel, insurance and overhead are concerned. They can only guess at cost of *upkeep* and *maintenance*. As repairs are unavoidable, and the cost of same a necessary item for the shipowner, more intelligence should be utilized in attending same. To know costs means closer relationship between *owners* and *repairs plants*, not through the good men previously mentioned, but through experienced men in such business.

Where owners use the right man in every branch of their operation, they use the wrong man in attending to their repairs. Any inexperienced man repairing a vessel at an established ship repair plant is doomed to incur excessive cost of repairs. There are many methods of hiding incompetency in the handling of this work—not because the incompetent man wishes to be dishonest—but it is unnatural for anyone to admit incompetency in his work, particularly where such admission may cause the loss of one's job; hence, there are many queer developments and excessive cost of jobs which are unnecessarily charged up against repair plants, and the regulation of such costs under the prevailing methods cannot be done.

The cost of such work continues to be unknown to the owner and will continue to be unknown to him just so long as present methods are used. Not until the business man, experienced in the cost of repairs, handles the repair work, so far as prices are concerned, for the owners, will the owners know the cost of such work! Considerable money may be saved by having such men attend this important feature and costs will be more properly distributed, giving thereby to the owner correct cost records.

Both Mr. Morell and Captain Gatewood are on the right track and quickly see wherein curative methods, or measures, may be effected; but it remains for most owners to realize that the best work his port captain and engineer can do is to see that the work required is properly covered, leaving the matter of cost to be handled by one who is experienced in such costs. The men to handle owners' costs are few and far between, but it remains for the owner to develop such men and to select them as they do their captains and engineers. Such men must have experience in the actual cost of repair work, and sufficient business acumen, to handle such an important business, and above all they must be of high character.

There can be no immediate result from these suggestions, but if we are to maintain our merchant marine and compete successfully for the world's transportation, some such method must be followed to realize, as soon as possible, such economies as may be effected in the cost of repairs, which will in turn lessen cost of operation.

EADS JOHNSON,
Consulting Marine Engineer,

New York.

Duties of a Marine Superintendent

In the March, 1923, issue of MARINE ENGINEERING AND SHIPPING AGE is an article entitled "The Duties of a Marine Superintendent," which, being associated very closely with that profession, was of particular interest to me and I feel prompted to amplify this subject. The article referred to, excellent though it was, did not, to my mind, fully cover the scope of a marine superintendent's duties nor the responsibilities of the position, and the fact was not brought out that the position holds with it unlimited opportunities for high grade service.

A marine superintendent of the proper sort can and should make himself the most valuable man in a steamship organization. A marine superintendent, in the true sense of the word, is not merely a port captain or a ship's husband, he is an executive charged with the entire technical, mechanical and physical upkeep and performance of the fleet. Such a man, to properly fulfill his duties, must be a high caliber business executive in addition to his technical qualifications, and must possess a versatility required of few other professions. He need not necessarily be an "old-timer"; live-wire and up-to-date methods are needed in combination with sound judgment. It is not a prerequisite that a man shall have obtained all of his experience at sea. Shipyard experience is just about as valuable as sea experience, and a combination of both is most desirable. Shipyard experience gives one an insight into the world's best marine practice, brings contact with hundreds of different vessels and problems, affords a first hand knowledge of the principles of design, construction and repair, and familiarity with shipyard methods and costs.

Beyond the few duties mentioned in the March article, the real and essential duties of a marine superintendent embody the following:

Entire field of repairs and maintenance of the fleet.

Entire physical performance of the vessels, involving all matters pertaining to engineering economy, and efficient installation and operation of the ship's power plant and other equipment.

Manning of vessels, i.e., selection of competent officers and handling crew matters, wage scale, etc.

Regulation of deck and engine stores as to selection of materials and limiting their use.

Protecting owners' interests in all accident cases.

Decision on all matters of building, purchasing or converting vessels for owners' use, with respect to size, type, characteristics and details.

Advisory to the management on general operating policy.

The above is written in the hope that it may give some marine superintendent a vision of the scope of his position and his possibilities for usefulness; a realization of his responsibilities and what is expected of him; a sense of pride in doing something really worth while.

Also in the hope that some steamship management, if they have the right man as marine superintendent, will realize that his opinion and advice are invaluable and will consult with him fully. If the judgment of the marine superintendent cannot be trusted, he is not the man for the job; get rid of him and get a man big enough to entrust with the fleet and its welfare; then give him a free hand.

MARINE SUPERINTENDENT.

Refrigerating Space Short in New York-Havre Service

Inability to obtain refrigerating space aboard ships plying in the New York-Havre service is ascribed as one of the reasons why the growing imports of frozen Canadian salmon into northern France are being transshipped through England.

PERSONAL MENTION

L. J. DUGAN has been placed in charge of the new offices of the Williams Line in Seattle, Wash.

J. R. EDWARDS has been appointed New York representative of the United States Barge Corporation of New Jersey.

ALBERTO DELLA RAGIONE has been appointed non-exclusive surveyor for the American Bureau of Shipping at Fiume, Italy.

W. B. KEENE, director of traffic, and Sidney Henry, director of sales, are now vice-presidents of the Emergency Fleet Corporation.

J. Y. S. MITCHELL, commercial agent, has been placed in charge of the new office of the Garland Steamship Corporation in Norfolk, Va.

EDWARD J. MEURER, for the past sixteen years connected with the W. & A. Fletcher Company, is now connected with the Perth Amboy Dry Dock Company.

EDWARD LOVERING, treasurer of the Massachusetts Cotton Mills, has been elected a director of the Eastern Steamship Company, succeeding J. B. Hardon, resigned.

NORRIS R. SIBLEY, formerly with the London Steam Turbine Company, has assumed new duties as representative of the firm of McClave-Brooks Company, 461 Eighth Avenue, New York.

J. B. SMULL, who recently retired as president of the Emergency Fleet Corporation, will resume activities on September 1 as a member of the firm of J. H. Winchester & Company, ship brokers and steamship agents.

ALFRED W. PARRY, JR., of the Tampa InterOcean Steamship Company, has been elected chairman of the Far Eastern Freight Conference for the next three months, succeeding Edward C. Trainor, of the Nippon Yusen Kaisha.

ARTHUR C. BESSELEVRE, at present with the United States Shipping Board, has been appointed professor of naval architecture, and Frank L. Odell has been appointed resident manager of the Webb Institute of Naval Architecture at Fordham, N. Y.

W. D. BENSON, formerly secretary of the Trans-Pacific Westbound Conference, has been named Seattle and Northwest agent for the Transmarine Corporation, which has inaugurated another intercoastal service from Port Newark to Seattle.

FLOYD N. BUSH has been appointed northwest manager of Sudden & Christenson, with offices at Seattle, his successor at Portland, Ore., being H. T. Anning, formerly in charge of the Portland office of the defunct Atlantic, Gulf & Pacific Steamship Corporation.

JOSEPH W. NEWBY, vice-president of E. E. Palen & Company, steamship agents, has been appointed general agent of the Old Dominion Transportation Company, at Norfolk, Va. Mr. Newby has been associated with the Old Dominion Steamship Company for twenty years. He will relinquish his active duties with E. E. Palen & Company, but will retain an interest and directorate in that company.

ARTHUR FLETCHER, of the W. & A. Fletcher Company, of Hoboken, N. J., in company with A. W. Preston, president of the United Fruit Company; Captain A. F. Davison, general manager of the marine department, and Mr. Moore, marine superintendent, sailed from Boston, on July 12, on the Cunard Liner *Samaria* for England. The purpose of the trip is to be present at the launching of the new steamship *La Playa* which has just been finished for the account of the

United Fruit Company by Messrs. Cammel Laird of Birkenhead, England, and is of the advanced Diesel electric drive design. The members of the party will return together to New York upon the new vessel.

J. BARRAJA-FRAUENFELDER, naval architect and marine engineer, who for the past nine years has had supervision over the high speed Diesel engine installations for the United States submarines built by the Lake Torpedo Boat Company, at Bridgeport, Conn., has resigned as chief engineer of that company. Mr. Frauenfelder has been retained by the Sun Shipbuilding and Dry Dock Company, of Chester, Pa., in the capacity of consulting Diesel engineer to undertake the development of the Sun-Doxford opposed piston Diesel engines for various commercial purposes.

OBITUARY

PETER CAHILL, eighty-two years old, founder and head of the Cahill Towing Line, Inc., died at his home in Brooklyn, N. Y., on July 18. Mr. Cahill was born in Rochester in 1841, spending his early days in that city and later in trade on the Erie Canal. He was a member of the National Board of Steam Navigators and also of the Maritime Association.

DAVID RODGERS, the best known shipbuilder on the Pacific Coast, died in Seattle, Wash., on June 25. Mr. Rodgers made an international reputation for speed in building ships during the war when he was superintendent for the Skinner & Eddy Corporation. In fact, it was probably the strain of his war-time efforts that caused his death for he had not been well for some time. Mr. Rodgers knew personally so many skilled workmen in the shipbuilding business that when the emergency building began he had little difficulty in securing the organization that helped him to make his wonderful record. Joseph E. Sheedy, vice-president, United States Shipping Board Emergency Fleet Corporation, has paid the following tribute to Mr. Rodgers:

"When the dreadful effect of the submarine employed by the Germans began to be felt so seriously and the world recognized the necessity of producing tonnage in ever-increasing amounts, it was Mr. Rodgers who first thrilled the country by delivering a complete 8,800-ton steel ship in 65 days—a year being required in pre-war days for this task.

"He thus set the pace for American yards in the production of ships, which later gained such headway that we were relieved of the frightful menace that threatened to cut off all assistance that we might render in the prosecution of the war.

"The first direct contract steel ship delivered to the United States Shipping Board was built by Mr. Rodgers and named the *Seattle*.

"Though he never sought to build ships in record time, just for the sake of establishing a record, he kept consistently cutting down the time of delivery of each vessel until he finally established 55 days as the construction time from keel laying until delivery of one of these huge vessels.

"When Mr. Rodgers was in Washington, in 1918, President Wilson sent for him and warmly congratulated him upon producing the most essential instrument of war in the record time that he had established.

"The United States Shipping Board in its untiring efforts to obtain tonnage at that time, awarded the pennant each six months to the shipyard delivering the greatest amount of tonnage based upon the number of building ways they occupied, and the Skinner & Eddy Corporation, under Mr. Rodgers' management, won this pennant on every occasion.

"Mr. Charles M. Schwab, when director general of the Fleet Corporation, named him the *Master Shipbuilder of the World*."

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

Outboard Profile of Type "A" Ship Proposed for Clyde Line and Designed by Theodore E. Ferris

New Steamer Under Consideration

ACCORDING to well-informed circles in the shipping district, the Bridgeport and Port Jefferson Steamboat Company has in contemplation the construction of a new steel steamer for the route between Bridgeport, Conn., and Port Jefferson, New York. George M. Tooker, of Port Jefferson, is superintendent of the line. It is understood that a New York naval architect has been consulted in connection with the preparation of plans and specifications.

It is believed that a vessel having an overall length of about 165 feet will be required and the propelling machinery will probably be either turbine or reciprocating engines. The line deals principally with the carrying of passengers and automobiles and a steamer to meet the new requirements will cost approximately \$175,000.

Bids for Construction of New Clyde Passenger and Freight Ships Received

PROPOSALS for the construction of two combination passenger and freight ships for the Clyde Steamship Company were received at the office of Theodore E. Ferris, naval architect and marine engineer, 30 Church street, New York, on Monday, July 23.

Two sets of plans and specifications were given to bidders, who submitted prices for two Type "A," or large sized ship, driven by turbine engines, and two Type "B" steamers, equipped with either reciprocating or turbine propelling machinery.

DIMENSIONS

The principal dimensions of each type of ship are as follows:

"A" Type	
Length overall	425 feet 6 inches
Length between perpendiculars	410 feet 6 inches
Length for displacement	405 feet
Beam molded	55 feet 9 inches
Depth molded to hurricane deck at side	32 feet 9 inches
Depth molded to main deck at side	24 feet 9 inches
Sheer forward	7 feet
Sheer aft	3 feet 6 inches
Designed load draft	18 feet 9 inches
Deadweight carrying capacity	3,160 tons
Cargo, cubic capacity	313,000 cubic feet
Speed	14¾-15½ knots

"B" Type	
Length overall	402 feet
Length between perpendiculars	387 feet 6 inches

Length for displacement	382 feet
Beam molded	54 feet
Depth molded to hurricane deck at side	31 feet 6 inches
Depth molded to main deck at side	23 feet 6 inches
Sheer forward	6 feet 9 inches
Sheer aft	3 feet 4 inches
Designed load draft	18 feet
Deadweight carrying capacity	2,650 tons
Cargo, cubic capacity	286,000 cubic feet
Speed	15 knots

The "A" type ships are to be equipped with geared turbine engines developing 4,750 shaft horsepower, turning a single screw, while the "B" type ships are to be driven by either geared turbine or reciprocating triple expansion engines, developing 3,900 shaft horsepower and also turning a single screw.

PASSENGER ACCOMMODATIONS

The larger ship will carry only one grade of passengers—first class in rooms and steerage passengers with men berthed in open spaces and women in a limited number of rooms. The first class passengers in rooms will be about as follows: two special suites with parlor room and connecting bath (4 or 6 passengers); 16 regular suites with connecting bath (32 or 48 passengers); 16 special rooms with settee, berth and connecting toilet (32 or 48 passengers); 10 special rooms with connecting toilet, no settee berth (20 passengers); 48 regular staterooms, no settee berth (96 passengers); making a total of 150 rooms for the accommodation of from 300 to 392 passengers.

The special suites are to be fitted with twin beds and Pullman folding berth over the inboard bed; four of the regular suites are to be fitted with one double bed with Pullman berth over, and twelve regular suites are to be fitted with twin beds and Pullman folding berth over inboard bed. All special staterooms are to be fitted with settee berth, while all regular staterooms will be fitted with lower and upper metal

Bids August 13 at Nashville, Tenn., for Two Derrick Boats

THE United States Engineer Office, Nashville, Tenn., will receive sealed proposals until 11 A. M., August 13, for the construction of two derrick boats. The vessels are to have a length molded of 76 feet 6 inches, beam 34 feet, depth molded at gunwales 5 feet. The hulls are to be built of steel, each to have a transverse watertight bulkheads. Forward, there will be two spud wells fitted into the hull near the gunwales, the wells to be 20 inches by 20 inches in the

clear and one spud well will be built aft to be 15 inches by 15 inches in the clear. A total of 49 complete sheaves with bushings and 12 extra complete sheaves with bushings are to be supplied.

The boom is to be 78 feet between end pins with a 14-foot removable section in the middle. The bull wheel will have an effected diameter of 16 feet and the "A" frame heads shall be about 43 feet 3 inches above the top of the deck.

bed in one unit. The total steerage passenger capacity will be 102.

GENERAL DESCRIPTION

The "A" type ship will be of the three-deck, hurricane deck, coastwise type, with fore-castle, deck well, bridge enclosure and continuous deck erections aft, with complete double bottom; and will have lower main, hurricane, promenade and boat decks. The ships will have two steel pole masts, forward mast fitted with cargo booms and main mast fitted with a small boom, and will have one smokestack. There are to be seven watertight steel bulkheads, all extending up to the main deck and three of which, including the collision bulkhead, will extend to the hurricane deck, forming eight transverse watertight compartments. The engine and boiler enclosures will be built of steel, extending to above the top of the boat deck house. The deck house and the hurricane deck will be of steel construction and the remaining deck erections, including the entire house on the promenade deck, boat deck, wheel, chart and wireless house, will be built of wood. The ship will be equipped with fans, motors and metal ducts, intake and exhaust fans to mechanically ventilate on the balance system to the upper and lower 'tween decks in cargo spaces.

The fore peak tank will be used for fuel oil and for salt water trimming tank. The after peak tank will be used for salt water trimming tank and will also be piped for fresh water, while the double bottom tanks will carry fuel oil, water ballast and boiler feed. Culinary water, or ship tanks, will be built in aft of the ship's engine space and at each side of the engine room between the double bottom and lower deck, the deep fuel oil tanks to be built in at each side of the boiler room between the double bottom and main deck. Steam cargo winches with cranes will be fitted at all blind hatch- es (five in number on the main deck) and steam winches will be fitted forward on the main deck for working the forward cargo booms.

Amidships on the main deck will be the galley, scullery, bake shop, mess room, storerooms, wash and toilet rooms, firemen's quarters, lamp room, trunk room, dog kennel, drying room, and stewards' cold storage rooms. Aft on the main deck will be waiters' quarters and wash rooms, men's steerage quarters and toilets and steering engine room.

PROPULSION

The propelling machinery will consist of double reduction geared turbines, steam being supplied by four single-ended Scotch boilers, fitted for burning oil fuel, arranged in one fireroom, together with all necessary auxiliaries. Other equipment will include electric light and power plant, cold storage system, steam winches, steam capstans, steam windlass, steam and auxiliary steering gear, emergency lighting set, wireless equipment, mechanical ventilating system, heating system and complete ballast and draining system.

In the case of "B" type ships the construction, general appearance and arrangements will be very similar to those of the larger ship. Their passenger capacity will be approximately 116 rooms for a total of between 252 and 306 first class passengers and 86 steerage passengers.

THE BRUNSWICK-KROESCHELL COMPANY is erecting new brick and concrete factory buildings at a cost of approximately \$500,000 at Diversey Avenue and the Chicago, Milwaukee and St. Paul right-of-way in Chicago.

Shipyards Requested to Consider Completion and Conversion of Three Southern Built 7,000 Ton Steamers

ANNOUNCEMENT is made by the firm of Whittlesey & Whittlesey, naval architects and marine engineers of 17 Battery Place, New York, of the disposition of three 7,000 deadweight ton steel cargo vessels which are in various stages of completion for the Italo-American Finance Corporation, to Callahan & Atkinson Company of 17 Battery Place. The vessels are the *Torino*, *Trento* and *Trieste*. The sale com-

pletes the liquidation of the International Shipbuilding Company's plant at Pascagoula, Miss.

Callahan Atkinson Company have sent a letter to various shipbuilders, which reads in part as follows:

"We give you below the information regarding the above vessels which were built under the supervision of Lloyd's and the Bureau de Veritas at Pascagoula, Miss., which are now available for inspection and sale. The dimensions of the vessels are as follows: 385 feet 9 inches overall, 52 feet molded breadth, 27 feet 6 inches molded depth. They are designed to carry 7,000 tons deadweight on 22 feet draft.

"Hull No. 1 (the *Torino*) has reciprocating engines and Scotch boilers, and it is estimated that there is sufficient equipment available to complete the steamer. Hulls Nos. 2 and 3 (the *Trento* and *Trieste*) have considerable equipment aboard and in the yards and they are adaptable for completion as motorships. It is estimated that they will carry about 7,500 tons so completed. All can be converted into barges with an estimated capacity of about 8,000 tons.

"If you can interest any of your clients we may arrange to defer payment for these hulls until they are ready for service and we may further extend financial assistance to approved buyers. We would also consider the completion sale of these vessels on a co-operative basis, the value of the ships and material and your cost of completion being subject to mutual arrangement. These vessels, when completed, should be very desirable as colliers or for the carriage of cargo such as ore, lumber, coal, etc., on account of the shallow draft of 22 feet. The above ships represent an original investment of several millions of dollars and are offered at considerably less than the current price of tonnage."

Invitations are extended to the shipyard to have representatives inspect plans, specifications, blueprints and photographs in order to develop some plan for the completion of the ships under terms that may be mutually agreed upon.

Southern Pacific Plans Building of Two New Steamers

PLANs and specifications are expected to be completed in about a month for the construction of two combined passenger and freight ships for the Southern Pacific Steamship Company. It is believed the vessels will be used in the company's southern service.

Sullivan Company to Build New Tug

THE contract for the construction of a 95-foot steel, oil burning tug for the Southern Pacific Company has been awarded to John W. Sullivan Company, on a bid of \$112,500, and 7 months' time. Tenders were opened by A. S. Hebble, Superintending Engineer of the Southern Pacific Company, on July 17, with the following results:

John W. Sullivan Co...	\$112,500	7 months
Federal Shipbuilding Co.	129,000	180 days
Staten Island Shipbuilding Co.	129,900	180 days
Tebo Yacht & Basin Co.	135,560	185 days
Bethlehem Shipbuilding Corp.	175,000	8 months
Sun Shipbuilding Co...	187,248	195 days

West Coast Yards Bid for Over \$200,000 Worth of Reconditioning on Point Bonita and Point Adams

AT the opening of bids submitted for reconditioning the steamers *Point Bonita* and *Point Adams*, under optional purchase by the Hammond Lumber Company from the Pacific Mail Steamship Company, the lowest tender was in excess of \$100,000. The vessels are considered well suited for the coastwise lumber trade, to which service they are to be assigned by the Hammond Lumber Company, if purchased by them. The purchase price has not been revealed.

The Bethlehem Shipbuilding Corporation submitted the lowest bid on the reconditioning of the steamer *Point Bonita*, while the Moore Shipbuilding Company was low bidder for repairing the *Point Adams* for the coastwise lumber trade.

The prices submitted for the *Point Adams* were: Moore's, \$111,034 and 50 days;

Bethlehem, \$115,136 and 52 days; Hanlon \$116,512 and 50 days; General Engineering \$118,210 and 50 days; Los Angeles Shipbuilding Company, \$118,700 and 60 days, a United Engineering, \$120,250 and 60 days.

On the reconditioning of the *Point Bonita* the tenders are: Bethlehem, \$103,680 and 48 days; Moore's \$106,028 and 50 days; General Engineering, \$106,410 and 50 days; United Engineering, \$108,000 and 50 days; Los Angeles Shipbuilding Company, \$113,350 and 50 days, and Hanlon's, \$114,880 and 50 days.

The work on both ships calls for the cutting off of the shelter decks, complete overhauling engines and boilers, installing cargo gears and winches and carrying out other work, generally fitting them for coastwise lumber trade.

Hamburg-American Steamer Cleveland Bought by U. A. L.

THE report that the Harriman interests are about to acquire the former Hamburg-American Line steamer *Cleveland* has been confirmed by R. H. M. Robinson, president of the American Ship & Commerce Corporation and the United American Lines. Mr. Robinson said that the American Ship & Commerce Corporation had been in negotiation for the purchase of the ship and that these negotiations were practically completed. The sellers are the Byron Steamship Company, Ltd., of London, who have been running her recently under the British flag as the *King Alexander*.

Mr. Robinson said that the liner would be operated by the United American Lines and that she would be employed as a cabin ship in the New York-Hamburg service under her former name, *Cleveland*. He said:

"While the *Cleveland* has always carried first, second and third-class passengers and is excellently equipped to do so, it is our plan to convert her into a cabin class steamer and to make her one of the most up-to-date vessels of that type afloat. She will be thoroughly reconditioned and is expected to go into service in about two months."

The *Cleveland* is a twin-screw steamer of 17,000 gross tons, and is well known to the American traveling public, having been employed by the Hamburg-American Line in the North Atlantic service and also for round-the-world cruises.

The United American Lines maintain joint services with the Hamburg-American Line. Three first-class ships, the *Resolute*, *Reliance* and *Albert Ballin*, are now in service between New York and the channel ports and Hamburg, and this number will be increased to four when the new *Deutschland* is completed later in the year. The cabin service between New York and Hamburg, heretofore maintained with the *Hansa*, *Thuringia* and *Westphalia*, will be increased to four ships by the addition of the *Cleveland*. An exclusive third-class service is also maintained, with the steamers *Mount Clay*, *Mount Clinton* and *Mount Carroll*.

Two Navy Ships to be Fitted Out in September

The Navy Department at Washington has announced that the new battleship *West Virginia*, being built at Newport News, will be sent to Norfolk to be "fitted out" as soon as she is turned over to the department. The *West Virginia* will probably be ready for the finishing process by September.

Admiral Andrews, commandant of the Fifth Naval District, stated recently that the Navy Department expected both the *West Virginia* and *Colorado* to be ready for the final stages of fitting out by September. Both ships will stop at the Brooklyn yard for installing of fire control apparatus before going to navy yards for the final process.

The Newport News Shipbuilding and Drydock Company has charge of the building of the *West Virginia* and the *Colorado* at Camden, N. J., the work being done by the New York Shipbuilding Company. The *Colorado* will go to Philadelphia to be finished after being turned over to the Navy.

Eight Companies Bid for Six Scow Construction Contract With Pittsburgh Yard Low at \$113,220

THE Dravo Contracting Company of Pittsburgh, Pa., submitted the lowest bid for the construction of six steel dump scows at the opening of tenders by the

United States Engineer Office, Louisville, Ky., on July 16. A variety of prices were asked and eight companies submitted proposals for the work as follows:

	One scow	Two scows	Three scows	Four scows	Six scows
American Bridge Co.....					\$145,500
Nashville Bridge Co.....	\$28,940	\$57,880	\$86,280	\$114,680	170,940
Independent Bridge Co.....	27,200	49,700	71,400	92,300	134,900
Dubuque Boat & Boiler Works..	24,800	46,800	68,400	90,000	133,000
Treadwell Construction Co.....				93,000	138,000
Penn Bridge Co.....					137,250
Dravo Contracting Co.....	20,500	39,540	58,410	77,080	113,220
General Contracting Co.....		30,000			*

*Informal bid.

Chas. Ward Low Bidder for Steel Stern Wheel Tug

THE Charles Ward Engineering Works, of Charleston, W. Va., with a price of \$164,000, submitted the low bid for the construction of a steel hull stern wheel tow-boat, bids for which were opened at the United States Engineer Office, Nashville, Tenn., on July 16. There was one other bidder, the Dravo Contracting Company, of Pittsburgh, Pa., who offered a price of \$189,000.

The proposed boat is to have an overall length of 136 feet 7½ inches, breadth molded 29 feet, the propelling machinery to be of the surface condensing tandem compound type, designed for a working pressure of 250 pounds per square inch, the vessel to be modernly equipped throughout.

Bidders for Building 14 Steel Barges

THE Mississippi River Commission, First and Second Districts, Room 1006 McCall Building, Memphis, Tenn, received sealed proposals on July 18 for the construction of fourteen steel barges, the Dravo Contracting Company, of Pittsburgh, offering the lowest figure of \$192,500. The proposed barges are to have a length of 120 feet, beam 30 feet.

The tenders submitted were as follows:

Dravo Contracting Co.	\$192,500
American Bridge Company	197,400
Midland Barge Company	207,200
Independent Bridge Company	212,730
Ritter Conley Manufacturing Co.	212,800
Penn Bridge Company	224,140
Nashville Bridge Company	249,740
Dubuque Boat & Boiler Works ..	297,000
Sun Shipbuilding & D. D. Co. ..	310,000

Construction and Equipment of Pier Shed to Cost About \$889,000; Proposals to Be Taken July 30

THE Commissioner of Docks of the City of New York received bids until July 30 for the construction and equipment of the West 44th Street Pier Shed, North River, Borough of Manhattan,

under Contract 1,810, the total estimated cost being approximately \$889,000. The work is to be divided into eight separate contracts as follows:

Contract	Estimated Cost
A Construction of Pier Shed...	\$713,000
B Elevators and Appurtenances.	58,000
C Baggage Conveyors	9,000
D Gravity Chutes	12,000
E Sprinkler Systems	39,000
F Steam Heating	11,000
G Plumbing and Water Supplies.	20,000
H Electric Wiring and Fixtures.	37,000

City Considering New Ferry Plans; Steamer Bought

THE Department of Plant & Structures of the City of New York submitted to the Board of Estimate & Apportionment, recently, new plans and specifications for the construction of eight steel ferryboats, these plans and specifications now being under consideration by that board.

The Department of Plant & Structures has purchased the steamship *Colonel Clayton*, which was built for the Government during the war for inland river service but was not used. The vessel is 130 feet in length and has been bought to replace the city institutional steamer *Correction*. The *Colonel Clayton* has been awarded to the Verdon Shipbuilding Company, Staten Island, for reconditioning at a cost of about \$10,000, the total purchase and repair price being \$50,000.

New Million-Dollar Terminal Project is Planned at Norfolk

THE Mallory and Gulf & Southern Steamship interests have purchased 1,200 feet of the Hendry & Knight terminals, at Tampa, Fla., from the Carew Land Company, the purchase price and contemplated improvement entailing an outlay of about \$1,000,000. This sale is probably the largest and also the most important waterfront transaction yet made in Tampa.

American Firm to Manufacture Ljungstrom Air Preheaters

ARRANGEMENTS have recently been made by James Howden & Company of America, Inc., in conjunction with James Howden & Company, Ltd., Glasgow, Scotland, for the sole marine license of the world to manufacture the air preheater developed

Phantom View of Preheater

by Frederick Ljungström, Stockholm, Sweden. In this country the preheaters will be made at the Wellsville Works, New York, of James Howden & Company.

The advantages of preheaters in general are well known and, for some time past, air preheaters have been used in conjunction with the Howden system of forced draft. Up to the present development, such air preheaters have generally operated on the

Rotor with Heating Elements

principle of transmitting the heat from the waste gases to the air through metallic surfaces separating the air passages from the flues. Under these conditions, heat transmission is not very effective, as the temperature difference is not great and the surfaces of the heating device have a tendency to become covered with a layer of soot or tarry matter which acts as a non-conductor.

In the Howden-Ljungström preheater, the assembly of parts is such that a large transmission surface is assembled in a rotating unit so that the elements are traversed first

by the waste gases from the boiler and then by the cold air used for combustion. The gases give up their heat to the elements and as they move into the current of cold air, the stored heat is transferred to the air.

OPERATION OF PREHEATER

Referring to the phantom view of the preheater, fresh air is drawn by a fan into the upper portion of the casing, which is divided into two parts by a vertical partition. The air is confined to one side of this partition and passes downward through a similar semi-circular chamber through the body of a porous cylindrical rotor. The flue gases from the boiler traverse the apparatus in the reverse way, entering the lower semi-circular chamber and passing upward through the rotor to the upper chamber, where they are exhausted and impelled to the stack by another fan. The rotor is kept in a state of continual rotation so that the portion heated by the flue gases is continually passing to the other side of the device and giving up its heat to the cold air sweeping through it.

Since there is no transfer of heat through metal in the process, the deposits of soot and tarry matter do not seriously affect the operation of the apparatus, which, moreover, may be cleaned readily by means of a steam jet.

The rotor is built of thin sheet steel and is divided into sections by radial plates which serve as stiffeners. In each section the heat elements, consisting of special corrugated plates alternating with plain plates, are placed concentrically, thus forming when assembled a honeycomb type of structure. This design allows liberal heating surface to be provided in a heater of comparatively small dimensions and with slight obstruction to the passage of the gases and air. On the outside of the rotor a heavy steel ring is fastened against which the carrying and guide rollers work. The integral fans are fitted on a common shaft and the required speed of the roller, about six revolutions a minute, is obtained by means of suitable gearing connecting the fan shaft with the driving roller. The rollers carrying the weight of the rotor are mounted on ball bearings so that the amount of power required for driving purposes is very small.

It is claimed that from 70 to 75 percent of the heat contained in the waste gases, depending on conditions, can be recovered with the Howden-Ljungström preheater, a result which is impossible unless with a type having a large extension of the heating surface which can only be made at the expense of space and weight as well as first cost.

Test figures from a Scotch boiler burning both coal and oil and fitted with this type of air preheater show exceptionally high boiler efficiencies, ranging from 84 to 87 percent.

S. S. Porto Rico to Be Converted for Refrigeration

BIDS were opened last month by the New York & Porto Rico Steamship Company for the conversion of the steamship *Porto Rico* into a refrigeration ship, the work to be done being similar to that recently carried out on the company's steamship *San Lorenzo*. It is expected that the contract will cost over \$100,000 and that another of the line's steamers will undergo similar reconditioning at a later date. Specifications for the *Porto Rico* were issued by Theodore E. Ferris, naval architect, of 30 Church street.

TRADE PUBLICATIONS

HYDRAULIC RIVETERS.—Riveters, hydraulically actuated, applicable to all kinds of ship, plate, tank and boiler work, are described in a bulletin issued by the Hanna Engineering Works, Chicago, Ill. Illustrations and descriptions of riveters, both regular and special types, are given in sizes from the 6-inch reach, 8-inch gap, 15-ton capacity forged nose riveter to the 126-inch reach 18- to 24-inch gap, 80-ton capacity boiler riveter.

BOILER TUBE CLEANERS.—A conveniently indexed catalogue descriptive of boiler tube cleaners has been sent out by the Roto Company, Hartford, Conn. Some of the sections into which the catalogue are divided deal with cleaners for watertubes, arch tubes, fire tubes, with condenser tube cleaners, various type motors used, accessories and repair parts.

ELECTRIC STEEL CASTINGS.—A group of bulletins outlining the process of manufacturing electric steel castings and their application in industry has been collected in binder form for distribution by the Nugent Steel Castings Company, Chicago, Ill., formerly the Electric Steel Company.

SAND AND GRAVEL DREDGES.—Bulletin F-196, illustrating and describing the elevator type sand and gravel dredge designed and built by Ellicott Machine Corporation, Baltimore, Md., has recently been published by this concern. In addition to general details and specifications of the dredge, including arrangement drawings, an outline of special machinery installed, including excavators' screening machinery, winding machinery, pumps and auxiliaries is also given.

LOUD SPEAKING TELEPHONES.—The marine type Callophone designed for service on board ship, in mines, tunnels and in other places where a watertight and non-corrosive equipment is required is described in a pamphlet sent out by the Callophone Company of New York. Specifications, wiring diagrams, methods of operation with suitable illustrations explain this system.

STEAM DRIVEN COMPRESSORS.—The Ingersoll-Rand Company, 11 Broadway, New York, has just issued a 36-page bulletin describing "Imperial" type XPV Steam Driven Air Compressors. This compressor is built in a number of different types and sizes. Standard two-stage machines for 100 pounds discharge pressure, range from 246 to 4,150 cubic feet per minute piston displacement. Single-stage compressors are built for furnishing air up to 50 pounds discharge pressure. One of the outstanding features of type XPV compressors is the automatic cut-off governor which regulates the compressor. Other features of design which are illustrated and described in detail include the Ingersoll-Rand plate air valves which are used for both intake and discharge; the unit construction which requires a very simple foundation; and the automatic flood system of lubrication.

MULTISTAGE SERIES PUMPS.—A new style of centrifugal pump, called a "series pump," is described in a catalogue just issued by the De Laval Steam Turbine Company, Trenton, N. J. In this pump double suction impeller and volute diffusers are used, as in single stage centrifugal pumps. The connecting passages from stage to stage, however, are included in the pump case casting, as in the ordinary multistage pump. The advantage claimed are perfect hydraulic axial balance and high efficiency under varying loads. A is characteristic of the single stage pump.

Foreign Shipping and Shipbuilding Activities

Semi-Diesel Engines Installed in Cargo Ship Margretian

TWO 600 horsepower marine oil engines of the semi-Diesel type have recently been installed by Messrs. William Beardmore & Company in the twin screw general cargo ship *Margretian* of Cardiff. The *Margretian* is of 6,525 tons displacement, 310 feet overall length, designed for service speed of 10½ knots.

A NEW DEVELOPMENT

This installation marks an epoch in the development of the semi-Diesel engine for it is the first attempt that has been made to build other than comparatively low power units of this type. The new type Beardmore engine consists of six cylinders each 18 inches diameter by 24 inches stroke, and is rated for 600 brake horsepower at 185 revolutions per minute. Each engine is 22 feet 6 inches in overall length, 5 feet 6 inches maximum width and 7 feet high above the floor plates. It weighs complete, with fly-wheel, silencer and exhaust pipes, about 45 tons.

The engine is of the two cycle type, with crank case compression and port scavenging, and has forced lubrication to all bearings, including the pump gear. The engine drives its own auxiliaries, with the exception of the air compressor which provides the starting air.

SPECIAL FEATURES

The lubrication of this engine has received special consideration, and, contrary to the usual practice with crank case compression machines, the crank shaft bearings have forced lubrication. The oil is delivered at 10 pounds per square inch to the main bearings. From there it is fed through the shaft to the big end and thence up the connecting rod to the gudgeon pin. The return oil is led to the service tank, where it is filtered and cooled before being returned to the engine. The pistons and cylinder walls are lubricated by mechanical sight feed lubricators worked by the engine.

So far as simplicity is concerned, this engine is the equal of earlier semi-Diesel types.

French Line Plans Construction of Two Large Transatlantic Liners; Company Passes Regular Dividend

By Our Paris Correspondent

CONSIDERABLE interest has been aroused in France by the general ordinary meeting of shareholders of the Compagnie Generale Transatlantique (French Line) which was held on June 29, as apart from the questions directly connected with the management of the company in the course of 1922, Mr. Dal Piaz, chairman of the board of the French Line, dealt in a very comprehensive speech with various questions pertaining to the present position of the shipping trade in this country and the general overseas policy of France.

The returns and accounts of the company

for the last year are far from being satisfactory since the total receipts amounted to 282,986,860 francs only, while the total of the expenditures for the same period was 262,781,341 francs: after deducting various charges, the net profit for the year under review works out to 155,821 francs only, and the board thus proposed that no dividend should be paid to shareholders, which proposal was agreed to by the shareholders.

Mr. Dal Piaz stated that the amount of the subvention which is granted to the company by the French Government in respect of the management of the mail service on the Havre-New York line has grown obviously insufficient in view of the increase in charges of all kinds which has been observed in the course of the last few years. For this reason the company has requested the Government to agree to a revision of the agreement of 1913 which still regulates the conditions of the subvention of the Government in that respect. A draft bill has been recently submitted to the Chamber of Deputies and it is hoped that the discussion thereon will take place in Parliament in the near future; such bill provides for a notable increase of the amount of the subvention.

At the same time Parliament will have to ratify the granting of a special subvention to the French Line which will enable them to place an order for a large new liner to be placed in service on the Havre-New York line in 1926. A second liner to be delivered in 1932 should be ordered by the company shortly after the first one. It is probable that these two liners will be ordered from the Chantier et Ateliers de Saint-Nazaire (Penhoet) which built the *Paris* and the *France*. These two liners should be built on the same lines as the *Paris*, in view of the satisfactory results obtained in service with the latter, which is a quadruple screw, turbine driven, oil burning vessel. The cost of these vessels should work out to about 100,000,000 francs each.

That the financial outlook of the company is improving is shown by the fact that the receipts for the first six months of 1923 have been 17 percent higher than for the corresponding period of 1922 while the expenditures have shown no increase.

French to Build Submarines Under New Naval Budget

THE 1,000,000,000 franc (\$62,500,000) naval budget voted upon by France recently provides for four 2,400-ton long distance cruising submarines. These submarines will cost at least 30,000,000 francs (\$1,875,000) each, construction probably being started this year. The budget also provided money for thirty 1,100-ton submarines to cost 15,000,000 francs (\$937,500) each.

The French navy now has about fifty submarines in service, including a number of good German submarines.

Owing to the nation's limited financial resources and also the restrictions of the Washington treaty, the French naval ministry wishes to increase the submarine program, and some money provided in the new budget for other craft will likely be devoted to laying down new submarines.

600 Horsepower Beardmore Marine Semi-Diesel Engine

Fiat Company Takes Over Turin Diesel Engine Works

TURIN, Italy.—Control of the Turin Diesel Engine Works, Via Cuneo, 20, formerly owned by the Ansaldo San Giorgio, has been acquired by the Fiat Company, original founders of the plant, which will carry on the business without change of personnel under the name of Fiat-Stabilimento Grandi Motori. The company will specialize in the construction of heavy oil, two-cycle engines for both marine and industrial purposes.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPBUILDING AND REPAIRS

Extensive Damage Work, Toledo, O.—The damaged steamer W. B. Schiller has been taken to Toledo for extensive repairs.

Contract Awarded, Baltimore, Md.—The lightship No. 52 has been awarded to the Spedden Shipbuilding Company for docking and repairs.

Steamer Drydocked, Chester, Pa.—The steamship W. D. Anderson has been drydocked at the Sun Shipbuilding & Dry Dock Company's yards, Chester, Pa.

Steamer Repairs, Cleveland, O.—The steamer S. J. Murphy, which broke her crankshaft on Lake Superior recently, has been towed to Cleveland for repairs.

Plate Repairs, Buffalo, N. Y.—The G. M. Wilson, a Boland & Cornelius boat, is in the Buffalo Dry Dock for repairs. Twenty-two plates are being replaced.

Tug Repairs, Jacksonville, Fla.—The tug Adler, of the Corona Coal Company of New Orleans, was taken to the Merrill-Stevens Dry Dock Company for repairs.

Nine Steel Barges, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company is constructing nine steel barges for the Tennessee Coal and Iron Company.

Collision Damage Repairs, Buffalo, N. Y.—The steamer Duluth, which received damages recently in a collision, is being repaired at the Ranahan Shipyards.

Steamer Repairs, Baltimore, Md.—The Shipping Board has awarded the contract for repairs to the steamer Monmouth to Theodore H. Rohde, Inc., at a bid of \$5,635.

Conversion to Oil Burner, San Francisco, Cal.—The Dollar Line steamer Stanley Dollar was awarded to the Bethlehem Shipbuilding Corporation, at a price of \$27,186.

Steamer Drydocked, Chester, Pa.—The American steamship Conejos has been drydocked at the Sun Shipbuilding and Drydock Company's yards, Chester, for miscellaneous repairs.

Vessel Repairs, San Francisco, Cal.—At the opening of tenders for repairs to the steamer West Isip, the Main Iron Works, San Francisco, Cal., submitted the lowest bid.

Plate Repairs, Lorain, O.—The steamer Secand-bee, recently damaged when it hit an obstruction in the Great Lakes, has been taken to Lorain for repairs to damaged plates.

Broken Propeller Repairs, Charleston, S. C.—The steamship West Iris, a Shipping Board vessel, has been taken to the Charleston Navy Yard to have a broken propeller blade replaced.

Voyage Repairs, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was low bidder for voyage repairs to the steamer Elkridge, of the Shipping Board, at a price of \$380.

General Reconditioning, Baltimore, Md.—The Curtis Bay Towing Company's tug Port Covington has been placed on the ways of the H. E. Crook Company for general reconditioning.

Cleaning and General Repairs, San Francisco, Cal.—The sea fighter Pennsylvania has been placed on the ways of the Bethlehem Shipbuilding Corporation for cleaning and general repairs.

Repair Work, Portland, Ore.—The steamer Pawlet, lighthouse tender Manzanita, for repairs; tug F. A. Douty, for repairs to propeller and to have her wheel fitted, were placed on the St. Johns drydock.

Ferryboat Launched, Buffalo, N. Y.—The new Grand Island ferry was launched recently and the finishing touches are now being completed by the Erie Basin Shipyards. The boat has been named the H. W. Long.

Contract Awarded, Kearny, N. J.—The contract for overhauling and general repairs to dredge No. 9, of the P. Sanford Ross Company, of Jersey City, has been awarded to the Federal Shipbuilding Company, at an approximate price of \$16,000.

Vessel Repairs, Philadelphia, Pa.—The Cramp Shipbuilding Company is making repairs on the coastwise tug Prudence and Government dredge Orleans. The Shipping Board steamship Western Spirit is also being repaired at the same yard.

Smooth Planked Dory, Staten Island, N. Y.—Sealed proposals were received by the Superintendent of Lighthouses, Tompkinsville, Staten Island, N. Y., on July 24, for a 20-foot smooth planked Swampscott dory, equipped with gasoline engine.

Shipyard Activities, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation received the following contracts: Admiral line steamer Admiral Farragut, general overhauling; transport Meiggs, general hull repairs; tankers Argyll and Lebec, general repairs.

Freighter Launched, Cleveland, O.—The American Shipbuilding Company recently launched the freighter Charles M. Schwab at Cleveland. The vessel has a length of 600 feet and is of 14,000 deadweight tons. She will be the largest boat in operation on the Great Lakes.

Shipyard Activities, West Coast.—The Eureka Boiler Works was low bidder for engine repairs on the liner Venezuela, of the Pacific Mail Company, and the United Engineering Company submitted the lowest figure for general repairs on the vessel, the prices being \$554 and \$681, respectively.

Lightship Repair Bids, Oakland, Cal.—At the opening of proposals for reconditioning Lightship No. 83 the Hanlon Drydock and Shipbuilding Company tendered a bid of \$4,099. Other bids for the work were: Moore's, \$4,230; De Young's, \$4,786; General Engineering, \$5,179, and Bethlehem, \$5,550.

Steamers Drydocked, Chester, Pa.—Steamer Steel Navigator, of the Isthmian Steamship Line, has been drydocked at the Sun Shipyard, Chester, for miscellaneous repairs prior to going to a Far East berth. The West Irmo has also been drydocked at the same yard for miscellaneous repairs and painting.

Shipyard Work, Mobile, Ala.—The steamship Gaston, for renewal of keel shoeing, etc.; repairs on the West Corum; steamship Normania repairs; boiler repairs on Fruit steamship Venator, and miscellaneous overhauling of the steamship Edgefield, have been awarded to the Alabama Dry Dock and Shipbuilding Company.

Low Bidder, San Francisco, Cal.—The General Engineering and Drydock Company was low bidder at the opening of tenders for repairs to the Government vessel George Armistead, which were as follows: General Engineering, \$2,174; Smith & Scanlon, \$2,321; Moore Drydock Company, \$2,357, and Hanlon Shipbuilding and Drydock Company, \$2,513.

Large Repair Contract, Oakland, Cal.—The Moore Drydock & Shipbuilding Company received the contract for making repairs to the boilers, renewal of nine furnaces and other general engine room repairs, to the Moore & McCormack Company, Inc., inter-coastal steamer Commercial Guide. The tender submitted by the Moore Company was around \$47,000.

Shipyard Activities, West Coast.—The General Engineering Company received the contract for repair work on the steamer Meton, the following bids having been submitted: General Engineering, \$5,883; Crowley's, \$6,369; Smith & Scanlon, \$6,770; Main Iron Works, \$6,300; Moore Drydocks, \$6,510;

Bethlehem, \$6,269, and United Engineering Company, \$6,555. For scaling the vessel, the same company was also low, with a price of \$4,775.

Ferryboat Launched, Wilmington, Del.—Pusey Jones, Wilmington, Del., have launched the steamer ferryboat Chelsea, which has been building for the Philadelphia & Reading Railway for service between Camden and Philadelphia. The boat is 22 feet long, 65 feet wide. Her sister ship, the Ocean City, now on the ways, will be completed in a few months.

Bids for Barges, Memphis, Tenn.—The Mississippi River Commission, First and Second Districts, Room 1006, McCall Building, Memphis, Tenn., received sealed proposals on July 18 for the construction of fourteen steel barges, the Dravo Contracting Company, of Pittsburgh, offering the lowest figure of \$192,500. The proposed barges are to have a length of 120 feet, beam 30 feet.

Lifeboats, Etc., Oakland, Cal.—The Pacific Boat and Manufacturing Company, of Oakland, has been awarded a contract by the army transport service for the construction of eight lifeboats and whale boats. The vessels will be of the latest design, equipped with life-saving equipment. The company recently delivered six lifeboats for the Southern Pacific Company for the new steamer Sacramento.

Shipyard Activities, Oakland, Cal.—The Hanlon Shipbuilding and Drydock Company was awarded the contract for extensive reconditioning of Hartwood Lumber Company's vessel Avalon, consisting of the installation of a new tail shaft, r lead sleeve and extensive engine and hull repairs as well as caulking. The revenue cutter Calhoun will go on drydock for repairs when the work on Avalon is completed.

Extensive Reconditioning, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company, Mobile, was awarded the following ship work: Steamer Cabrille, for examination, opening up of all engine boilers and auxiliaries for inspection, outside scaling, four coats of paint, etc.; steamer Venator, repairs; steamer Gaston, tug Coloso, miscellaneous repairs; and steamer W. land, plate repairs, decks calked, engine repairs, etc.

Two Ferryboats Reconditioning, Oakland, Cal.—Ferryboat Cazadero, owned by the Northwest Pacific Company, is being entirely reconstructed at Oakland shipyards, at a cost of \$200,000, to render it in condition for increased passenger and mobile service between San Francisco and Sausalito. The Old Thoroughfare, of the Southern Pacific Company is also being rebuilt at the company yard, to operate between Oakland and San Francisco.

Vessel Contracts, Panama Canal Zone.—The following vessels were recently taken to the Cristobal shops for repairs: launch Dalia, repairs to shaft, stern bearing, caulking deck seams, etc.; steamship Ulysses, scale and paint hold; marine D-3, remove bow rudder, overhaul 10 gun clean and paint all tanks, and several other important repairs; tug Tavernilla, mineplanter ham, steamships Acajutla, District of Columbia, Heffron, Balboa, Oriana, Ucayali, Cristobal, etc.

Contract Awarded, Baltimore, Md.—Under proposals received and opened at the office of United States District Engineer at Philadelphia, Pa., on June 22, the contract for four 50-foot motor tugs has been awarded to the Spedden Shipbuilding Company, of Baltimore, Md., the low bidder for the four tugs combined at a total of \$112,337, based on the installation of Kalberg 100-horsepower engines. Delivery of the tugs will be accepted by the United States at the yard of the contractor.

Repair Work, Buffalo, N. Y.—The Oldman-Miller Boiler Works, Buffalo, are completing repair

the steamer Usona, of the White, Mitchel & Gratiwick Line. They are rebuilding her hatches and deck and overhauling the boiler. The same yard has completed overhauling boilers of the British Ship Belchers. Repairs are being made at the Riley Dry Dock Company to Barge No. 214, of the New York Canal & Great Lakes Corporation, four new plates, caulking and replacing of 500 rivets comprising the necessary work. New stern planks have been installed in Barge 501 belonging to the same company.

Bids for Sternwheel Towboat, Memphis, Tenn.—The Charles Ward Engineering Works, of Charleston, W. Va., with a price of \$164,000 submitted the low bid for the construction of the steel hull stern wheel towboat, bids for which were opened at the United States Engineer Office, Nashville, Tenn., on July 16. There was one other bidder, the Dravo Contracting Company, of Pittsburgh, Pa., who offered a price of \$189,000. The proposed boat is to have an overall length of 136 feet 7½ inches, breadth molded 20 feet, the propelling machinery to be of the surface condensing tandem compound type, designed for a working pressure of 250 pounds per square inch, the vessel to be modernly equipped throughout.

Shipyard Activities, West Coast.—The United Engineering Works tendered the lowest bid for general voyage repairs to the U. S. transport Grant, the prices submitted being as follows: United Engineering, \$1,423; Hanlon's, \$1,672; A. De Young, \$1,713; Bethlehem, \$1,738; Neptune Metal Works, \$1,897; and Moore's, \$1,987. The West Chopaka was discharged from the Bethlehem yard after completing cleaning and painting. The Mauna Ala is on the Bethlehem ways for cleaning, painting and to have her propeller changed; the Mexican steamers Oaxaca and Chihuahua were discharged from the Union Iron Works after undergoing repairs, and the Manoa and Sonoma are on the ways of the Bethlehem Shipbuilding Company for repairs. The Hanlon Shipyards are busy on the schooner Fred J. Wood and the steam yacht Virgana.

PORT IMPROVEMENTS

Sea Wall, etc., Greenwood, Miss.—Plans are being made for a sea wall on the left bank of Yazoo River. \$15,000. W. S. Hawkins, engineer.

Grain Elevator, Hopkinsville, Ky.—Acme Mills plan 40 by 100-foot grain elevator, 100 feet high, reinforced-concrete, 200,000 bushels capacity. To exceed \$25,000.

Levee, Waxahachie, Tex.—Ellis Company, Levee District II, plans to reclaim 1,500 acres, levees on North Side of Chambers Creek. \$52,000. W. H. Stovall, county judge.

Dredging, Huron, Mich.—U. S. Engineer, Detroit, awarded the contract for dredging Black River Channel, Port Huron, to Port Huron Sulphite & Paper Company. \$12,700.

Grain Elevator, etc., Pelican Rapids, Minn.—H. E. Frazee is having plans prepared for a grain elevator and feed mill, brick and concrete. \$40,000. Duvar & Milinowski, 500 Globe Building, St. Paul, architects.

Hydraulic Dredging, etc., Key West, Fla.—Paul Boyesen Development Company has had estimates made on 150,000 cubic yards of hydraulic dredging and fill. \$37,500. B. Curry, Moreno, and P. Boyesen, Key West, engineers.

Channel Changes and Excavation Plans, Sioux City, Ia.—The city is making plans for changing the channel of Perry Creek, 50,000 cubic yards of excavation, etc. \$335,000. L. N. Hintgen, Sioux City, engineer.

Estuary Work, Tampa, Fla.—The City Commissioners of Tampa, Fla., have awarded the contract for the work of constructing the new municipal port terminals on the Ybor estuary to McGuckin, McGuckin & Edwards, of Tampa.

Contract Awarded, Ottawa, Ont.—The Department of Public Works, Parliament Building, Ottawa, Ont., awarded the contract for dredging in the harbor of Ft. William and Port Arthur, to J. S. Pratt, Midland. Estimated cost \$300,000.

Dock and Terminal, Portland, Ore.—The Oregon, Washington Railway and Navigation Company, Velle-Fargo Building, plans new Albina Street dock, \$228,000, and terminal, \$197,488. S. Murray, assistant chief engineer, in charge of the work.

Bulkhead Award, Pensacola, Fla.—Specification 4837. Bureau of Yards and Docks, Navy Department, Washington, D. C., awarded the contract for replacing bulkhead at Naval Air Station, to C. H. Turner, 12½ South Palafox street. \$31,994 (240 days).

Pier, San Diego, Cal.—Sealed proposals were received by City Council, July 11, for constructing a portion of mole type pier project, including concrete wharves, also sides and ends of pier wall. \$300,000. F. G. White, Ferry Building, San Francisco, engineer.

Grain Elevator, Fort Worth, Tex.—Fort Worth Elevator Company, 1510 East 1st street, awarded the contract for a reinforced-concrete grain elevator, 1,750,000 bushels capacity, to Southwestern Engineering Company, Woodruff Building, Springfield, Mo. \$1,500,000.

Wharf and Dock, Detroit, Mich.—The Public Lighting Commission, Atwater street, East, awarded the contract for a reinforced-concrete wharf and dock, at site of proposed lighting plant, to Greiling Brothers, 100 Blk. East Walnut street, Green Bay, Wis. \$417,400.

Piers, San Francisco, Cal.—State Board of Harbor Commissioners, Ferry Building, is having preliminary plans prepared for three piers, from 285 feet to 350 feet wide and from 1,200 to 1,500 feet long, with sheds 115 feet wide. F. G. White, Ferry Building, chief engineer.

Air Compressor, etc., for Grain Elevator, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Court Building, July 19, for furnishing an air compressor and receiver for the public grain elevator. Requisition G. E. 1445.

Dike, etc., Biron (Wisconsin Rapids P. O.), Wis.—Consolidated Water Power & Paper Co., Wisconsin Rapids, awarded a contract to Rood Construction Company, Wisconsin Rapids, for a 2-mile dike, 100,000 cubic yards, approximately 10,000 cubic yards of rip rap, 10,000 cubic yards of rock excavation, in connection with drainage project.

Dock and Boat Basin, Sanford, Fla.—The contract for furnishing for a dock and boat basin, 24,000 cubic yards of hydraulic sand fill, 1,750 cubic yards of reinforced-concrete, 35,000 lineal feet of wood piling, 76,000 pounds of steel, 11,000 feet creosoted timber, etc., was awarded to the Interstate Contracting Company, Sanford, at a price of \$68,887.

Hydraulic Dredging, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, at their office, Suite 200, New Court Building, July 26, for hydraulic dredging from 750,000 to 1,500,000 cubic yards in the Inner Harbor Navigation Canal between the Lock and Louisville and Nashville Railroad bridge. J. H. Walsh, general manager.

Sea Wall or Flood Protection, Vicksburg, Miss.—Sealed proposals for the construction of a concrete wall along the river front at Vicksburg, Mississippi, were received at the City Hall, July 2, approximately 4,200 lineal feet of wall containing about 9,500 cubic yards of concrete, 450 tons of reinforcing steel and 4,200 lineal feet of interlocking sheet piling 10 to 20 feet long, being contained in the work.

Slip to Be Enlarged, Baltimore, Md.—The slip at the Merchants & Miners Transportation Company's docks is to be dredged out twelve feet further back towards Bay street, steel piling and a concrete bulkhead will then be installed and the whole slip dredged to the same depth. This work is being done by the company to facilitate the loading and unloading of its two new ships, the Alleghany and Berkshire.

Inlet Improvement, Fort Pierce, Fla.—A bond issue of \$220,000 has been authorized for the improvement of the Fort Pierce Inlet to provide a channel depth of 14 feet and extend the jetties a sufficient distance east and west to adequately protect the project. The Fort Pierce Finance and Construction Company will provide the ship channel, turning basin and pier in connection with the building of a causeway across Indian River.

Jetty Contract, Wilmington, N. C.—The contract for building a series of jetties along the Wrightsville Beach ocean front has been awarded to Jesse A. Howland of Sea Bright, N. J. The price for carrying out the work is \$27,721.50. There are to be five different jetties, the extreme ones being about one and one-half miles apart. One will jut out at a point north of the Oceanic hotel, one

south of Lumina and the three remaining will be placed at varying intervals along the beach. They will vary in length from 250 to 350 feet. The material will be wooden sheet-piling.

Wharf and Grain Elevator, Portland, Ore.—Oregon, Washington Railway and Navigation Company, Montgomery Ward Building, has had plans prepared for a 137 by 360 foot wharf at Albina Dock, covered shed 24 feet high, 180 feet double track trestle, 80 by 120 foot open wharf, wheat elevator, 104 feet high, capacity 310,000 bushels, and 119 by 350 foot warehouse. \$220,000. S. Murray, Montgomery Ward Building, assistant chief engineer.

NEW INCORPORATIONS

The Pacific-Caribbean-Gulf Line, capital \$1,000,000, chartered under Delaware laws.

The Callaghan Transportation Corporation, capital \$100,000, chartered under Delaware laws.

Western Transit Corporation, capital \$100,000, chartered in Delaware, to build and operate boats.

The Nautilus Steamship Corporation of Manhattan has increased its capitalization from \$800,000 to \$900,000.

The Pacific-Caribbean-Gulf Line, capital \$1,000,000, chartered under Delaware laws. Incorporators: Steele Steamship Line.

The General Marine Salvage Corporation, capital \$750,000, chartered under Delaware laws. Corporation Trust Company of America, registrars.

The General Marine Salvage Corporation, capital \$750,000, incorporated under Delaware laws. Incorporation Trust Company of America, registrars.

California-New York Steamship Company, capital \$12,500,000, incorporated in Delaware. Delaware Incorporating Company, registrars, Wilmington.

The C. & G. Salvage Corporation, of Manhattan, capital \$100,000, chartered at Albany. Incorporators: B. & J. P. Greenstone and A. M. Garbade.

The Bison Steamship Corporation, of Tonawanda, N. Y., capital \$150,000, chartered at Albany. Incorporators: J. J. and M. O'Hagan and J. Gehm.

The Morecraft Transportation Corporation, of Wilmington, Del., capital \$500,000, incorporated under Delaware laws, to engage in the operation of boats.

Intercoastal Shipping Service, of Manhattan, capital \$20,000, chartered under New York laws. Incorporators: G. V. Reilly, S. C. Wood and H. C. Hand.

The International Trade Developer Corporation, to foster world trade, capital \$1,000,000, incorporated in Delaware. Incorporators: Z. G. Dunn, C. H. Stanley and A. J. Brook, of Chicago.

The New York, Atlantic City and Philadelphia Steamship Company, capital \$2,000,000, incorporated in New York. The beginning of this line will give Philadelphia two services to New York.

The Diesel Steamship Company, capital \$25,500,000, chartered under Delaware laws. Incorporators: Edward Whitton, of Chatham, N. J.; Edwin A. Quick, of Brooklyn, and P. Tyson, of New York.

The Mexican, American Fruit & Steamship Corporation, capital \$12,000,000, organized under Delaware laws. Incorporators: F. J. Porter, Montgomery B. Angell and Otis T. Bradley, of New York.

The Pacific Mail Corporation, capital \$1,000,000, incorporated under Delaware laws. Incorporators: F. M. Stokes, of Woodhaven, L. I.; Joseph F. Mann, of Bloomfield, N. J., and William D. Ahearn, of Brooklyn.

Philadelphia Derrick & Salvage Corporation, capital \$500,000, incorporated in Delaware. Incorporators: Clinton E. Rowe, of Whitestone, New York; Charles P. Kramer, of Far Rockaway, N. Y., and Joseph Lilly, of Brooklyn.

United American Terminals, to do wharfage and freighting, capital \$100,000, chartered under Delaware laws. Incorporators: Eugene C. Tobey, of New York; Allen W. Lishawa, of East Orange, and William T. Dunn, of Long Island City.

The Knowl Trading Company, capital \$100,000, incorporated under Delaware laws, to do business as shipbrokers. Incorporators: George S. Brengle, of Arlington, N. J.; Hurlburt McAndrews, of Mam-

aroneck, N. Y., and P. J. R. McIntercept, of New York.

The McCormick Steamship Company of San Francisco, capital \$500,000, has been reorganized with the following officers: Charles R. McCormick, president; Sydney M. Hauptman, vice-president; Charles L. Heutter, second vice-president and general manager, and J. S. Brown, secretary and treasurer. John M. Hencken has been appointed operating manager of the company, and J. C. Strittmatter, freight manager. The Munson-McCormick Line operate a joint inter-coastal service.

GOVERNMENT WORK

Dredging, Galveston, Tex.—U. S. Engineer Office, Galveston, received bids July 20 for dredging the Houston Ship Channel.

Dredging, Galveston, Tex.—Bids were received July 21, at the office of the United States Engineer, Galveston, for dredging in Texas City Channel.

Bids Rejected, Milwaukee, Wis.—U. S. Engineer, Federal Building, Milwaukee, rejected bids for dredging approximately 450,000 cubic yards at Green Bay, Wis.

Dike, St. Louis, Mo.—United States War Department, Federal Building, Kansas City, plans concrete and rubble dike at mouth of Missouri River, near St. Louis.

Dredging, New Jersey.—U. S. Engineer Office, Wilmington, Del., received sealed proposals, July 9, for dredging Maurice and Cohamsey Rivers, N. J. Further information on application.

Six Dump Scows, Louisville, Ky.—Sealed proposals were received by U. S. Engineer Office, July 16, for furnishing and delivering six steel dump scows. Further information on application.

Dredging, New Orleans, La.—Sealed proposals were received by the U. S. Engineer Office, New Orleans, July 19, for dredging in the Calcasieu-Sabine section of the Intracoastal Waterway.

Dredging, Detroit, Mich.—U. S. Engineer, 337 Federal Building, Detroit, plans dredging Saginaw River to restore 18.5 feet of channel in Saginaw Bay and 16.5 feet channel in Saginaw River.

Steel Derrick Boat, St. Paul, Minn.—Sealed proposals were received by United States Engineer Office, July 31, for constructing and delivering a steel derrick boat. Further information on application.

Dredging, Providence, R. I.—U. S. Engineer, Providence, awarded the contract for dredging in Duck Island Harbor, Conn., to Columbia Dredging Company, 30 Church street, New York City. \$36,800.

Excavation, Wilmington, Del.—U. S. Engineer, Wilmington, Del., will receive sealed proposals until August 2 for excavating the inland waterway from Delaware River to Chesapeake Bay, Delaware and Maryland.

Reboiling Tug, Florence, Ala.—The United States Engineer Office of the War Department, Florence, Ala., is reboiling the tug General John Coffee. Foster radiant heat type superheaters are to be installed.

Fourteen Steel Barges, Memphis, Tenn.—The Mississippi River Commission, First and Second Districts, Room 1006, McCall Building, Memphis, received sealed proposals July 18 for furnishing fourteen steel barges.

Dike, New York, N. Y.—U. S. Engineer, 616 Army Building, awarded the contract for a 3,400-foot timber dike north of Shooters Island, New York and New Jersey, to Rhodes & Manvel, Inc., 90 West street. \$75,785.

Contract Awarded, Nashville, Tenn.—U. S. Engineer, Custom House, awarded the contract for 365,000 feet of yellow pine timber for Lock and Dam 8, Cumberland River, to Great Southern Lumber Company, Bogalusa, La. \$18,000.

Stone for Rubble Mound, Alpena Harbor, Mich.—Sealed proposals were received by the United States Engineer Office, Detroit, Mich., July 30, for furnishing and placing stone for rubble mound at Alpena Harbor, Mich. Further information on application.

Breakwater, Alpena, Mich.—Bids will be received by U. S. Engineer Office, 337 Federal Building,

Detroit, until July 30 for 11,700 tons of core and 10,300 tons of Armor stone, etc., for a rubble mound breakwater, 1,030 feet long at the southerly side of the river mouth.

Derrick Boat, Memphis, Tenn.—Sealed proposals were received at the office of the Mississippi River Commission, First and Second Districts, Room 1006, McCall Building, Memphis, Tenn., July 19, for furnishing one 25-ton steel derrick boat, complete. Further information on application.

Contracts Awarded, Los Angeles, Cal.—The United States Engineer Office, Los Angeles, awarded the contract for the dredging of the main channel of Los Angeles Harbor to widen it from 500 to 1,000 feet, to the San Francisco Dredging Company and the Fred C. Frank Construction Company.

Stone Riprap, Keweenaw Waterway, Mich.—Sealed proposals were received by the U. S. Engineer Office, Duluth, Minn., July 3, for removing timber superstructure and furnishing and placing stone riprap along and on the west breakwater, Upper Entrance of the above waterway. Further information on application.

Bids Rejected, Buffalo, N. Y.—The U. S. Engineer Office, Federal Building, Buffalo, opened bids on the twentieth for dredging and rock excavations in the Black Rock Canal, Buffalo. All bids were deemed too high, and part of the work, consisting of the triangular area, will be re-advertised, probably about September 1.

Runners, Wilmington, Del.—Sealed proposals, in duplicate, will be received at the U. S. Engineer Office, Wilmington, N. C., for two runners, port and starboard, for 15-inch pumps in dredge Comstock, the runners to be cast steel, machined, bored, keyseated, fitted with inboard and outboard liners, ready to install, delivered f. o. b. cars, Wilmington, N. C.

Harbor Improvement, Philadelphia, Pa.—The contract for dredging in Delaware River, Philadelphia Harbor, 201,000 cubic yards excavation, minimum allowable over depth 84,000 cubic yards, has been awarded to the American Dredging Company, Mariner and Merchant Building, Philadelphia, by the United States Engineer Office, 815 Witherspoon Building. Price \$68,340.

Sale of Used Equipment, Panama Canal.—Sealed proposals for the purchase of railroad, marine construction, mechanical, electrical, and miscellaneous equipment, will be received at the office of the General Purchasing Officer, The Panama Canal, Washington, D. C., until 10:30 o'clock a. m., August 2, 1923, at which time they will be opened in public for purchasing the above-mentioned equipment. Blanks and information relative to this circular (1525) may be obtained from this office. A. L. Flint, General Purchasing Officer.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

A Great Loss

THE people of these United States have suffered a great loss in the untimely death of President Harding. All classes of men and women in every industry have felt and expressed this loss with genuine sorrow but none more than those who build and operate ships.

Our President was the greatest friend of the merchant marine. It was his dearest wish that American shipping should be developed and firmly established during his administration on a basis adequate to serve our commercial and naval needs. If he had received the support in Congress that he should have had from his own party, his ambition would now be well on its way to fulfilment.

There is nothing that we can do that would please our departed leader more or do him greater honor than to carry out his wishes in this respect. He never wavered in his determination to secure such legislation as would encourage private interests to embark on shipping ventures. Let us, therefore, "gird up our loins" and fight with renewed vigor so that President Harding's name may be perpetuated as the father of the American merchant marine.

An Imperative Demand

THE Chamber of Commerce of the United States, commercial, manufacturing and business organizations and every man in the street who believes in the principles upon which this country has become great demand that Government operation whether it be of ships, railroads, mines or bureaucracy in general should and ought to be avoided except as a last extremity in great emergencies.

The Shipping Board has alarmed the entire business world with its plan of direct operation. At this writing the board itself has split on the exact method it proposes to adopt. Four of the commissioners favor the creation of eighteen subsidiary companies of the Emergency Fleet Corporation and three commissioners favor centralized direct operation of the entire fleet.

Referring to the plan for eighteen subsidiary corporations, we have already pointed out in a recent editorial that such a method could only result in multiplying the losses that the Government is now sustaining. Again, even if the efficient heads of the present operating companies could be induced to accept the positions of presidents of these corporations, everyone familiar with political procedure would know that their resignations would have to be handed in upon acceptance of their jobs. Then just as soon as they got their particular corporation going at all straight some politician would have a friend who he thought ought to have their job and out they would go.

As to the direct operation of the fleet as a whole, the only comment that we wish to make is that we do not believe that the most efficient business organization in existence could take over such a stupendous proposition and make a success of it.

The Shipping Board was created to devise ways and means of rendering Government assistance to the merchant marine. Why is it worrying and spending its entire time over a form of contract which at least is creating experienced shipping executives? Everyone knows that some form of Government aid is necessary in order to interest private capital in shipping. Why are they not devoting their time to this, the major factor, and to the revision and codification of our navigation laws?

We cannot believe that President Coolidge will sanction Government operation in view of the obvious opposition of all commercial interests and also with the knowledge that such a policy has been condemned more than once by the late President Harding. It is gratifying that the board postponed action until the shipowners and operators presented

their case on August 28 and we trust that, if it is not convinced of the danger of its proposed course by this conference, it will at least delay action until the representatives of all classes of industry from the entire country voice their sentiments at the American Marine Congress to be held in New York during the week of November 5-10.

The Philippine Mandate

SECTION 21 of the Merchant Marine Act of 1920 relating to the extension of our coastwise laws to include the Philippine Islands still remains inoperative. Not only has Congress directed in this section that after February 1, 1922, the coastwise laws shall extend to the Philippines and all other possessions of the United States not then covered thereby, but it has also directed that the Shipping Board before the expiration of that year should see to it that adequate steamship services at reasonable rates were established.

There can be no loophole for the evasion of the enforcement of Section 21 except that of the lack of shipping facilities to handle the passenger and freight business between the Philippines and the United States. And, in this connection, even if there were any doubt about the language of Section 21, the board has only to turn to Section 7. This section also specifically directs that the board "investigate and determine as promptly as possible after the enactment of this Act what steamship lines should be established and put in operation from ports in the United States, any Territory, District or possession to such world and domestic markets as in its judgment are desirable for promotion, development, and expansion of the foreign and coastwise trade of the United States."

It is known that President Harding on several occasions had considered putting this section into effect. Has the board with all its surplus tonnage neglected to provide adequate shipping facilities and, if so, why? Mr. Vincente Villamin, Philippine expert, recently stated that there were 1,272,780 tons of shipping engaged in the Philippine trade, of which 448,971 tons were British and 405,273 tons American. Is this trade carried in foreign vessels not desirable for American ships or is there some reason more potent than the laws on our statute books that prevents the proper development of our merchant marine?

We believe that we have not far to look for such a reason. Is it not the influence of shippers and exporters both in this country and the Philippines who may fear that the confinement of this trade to American vessels would increase the freight rates? That such would not be the case may be seen from a comparison of the rates charged including both east and west bound voyages between New York and San Francisco. The distance between these ports is approximately the same as the distance from San Francisco to Manila.

From figures obtained from Mr. R. T. Merrill, director of the Bureau of Research of the Shipping Board, the average freight rates for five months on the vessels of the Nawsco line between New York and San Francisco were \$8.37 as compared with an average freight rate of \$7.17 to the Orient. Thus it will be seen that there is very little difference between American vessels and the vessels of other nations. It

should be added that Panama Canal tolls were deducted from the coastwise figures to make the comparison fair.

No one can doubt the wisdom of the coastwise laws as they are now applied. They have caused a phenomenal growth in American shipping plying between our Atlantic and Pacific seaports. The same would be true in regard to the Philippines and, still further, it would be of great advantage to our commercial development and to the creation of an adequate auxiliary Naval Reserve.

Awakening Public Interest in American Shipping

IN an article widely published throughout the United States through the Hearst Newspaper Feature Syndicate and the subject of extensive editorial comment Colonel E. A. Simmons, president of the American Marine Association, states that the passenger business being given American flag ships is such as to fill to capacity the greater number of those in service and that a much heavier percentage of travelers use American steamers than foreign steamers, as gaged by the carrying capacities of the respective lines engaged in trade.

"My investigation shows that the favor of travel has been turned to American ships," says Colonel Simmons, "solely because of the service that is being given and not for any patriotic reason. . . . Eventually, I believe that the support which is now being so generously given our passenger ships will bring about on the part of American people a desire that our freight or cargo ships be given such patronage as will make them the talk of the seas, as our passenger ships have already become."

It is the bringing of such first hand information directly to the majority of the American people that will arouse public support of our ships and stimulate patronage not only for American passenger vessels but also for American cargo ships. As pointed out by James A. Farrell, president of the United States Steel Corporation, in speaking before the National Trade Council at New Orleans: "The greatest subsidy our ships could have in the overseas trade would be the support of the American people."

The Marine Exposition

THE annual Marine Exposition, which will be held during the week of November 5-10 at the Grand Central Palace, New York city, will have a decided influence on the delegates from the commercial, manufacturing and farming organizations who will attend the American Marine Congress that will occur during the same week.

It is very gratifying and encouraging to note the interest that the large number of organizations from the interior of the country are taking in this Congress. Sixty-eight organizations, listed on page 522 of this issue, have already appointed representatives. The truth of the matter is that the people of the interior are awakening to the fact that we must have an adequate merchant marine.

The marine field, therefore, is under a decided obligation to give these delegates every bit of marine information that is possible and there is no better way to do this than to make this year's exposition the largest and best ever given.

James Swan, Noted Naval Architect, to Join Editorial Staff of Marine Engineering and Shipping Age

Former Shipyard Executive, Well Known in This Country and Abroad, Resigns Shipping Board Post to Take Up Editorial Work This Month

JAMES SWAN, naval architect of the ship sales' division of the United States Shipping Board, has resigned to join the editorial staff of MARINE ENGINEERING AND SHIPPING AGE. In taking up his editorial work this month Mr. Swan brings to the magazine an intimate knowledge of the problems confronting the Shipping Board, gained by one and one half years in charge of a comprehensive survey and valuation of its fleet, together with a wealth of experience gained in the shipbuilding field both as a ship designer and as a shipyard executive.

As a preliminary to entering upon his editorial duties, Mr. Swan sailed for England on the *George Washington*, September 1, to attend the British Shipping Exposition and a meeting of the Institution of Naval Architects.

AN M. I. T. GRADUATE

Mr. Swan is a native of Boston, Mass. His parents were of English descent, his father's family having come from Newcastle, England, in 1635 and settled in what is now Cambridge, Mass. He was educated in the Boston public schools and the Massachusetts Institute of Technology, graduating from that institution in 1891 with the degree of Bachelor of Science in the Department of Mechanical Engineering.

Having become much interested in marine engineering which, at that time, was taught in a limited way at the Institute as a branch of the course in mechanical engineering, Mr. Swan, after his graduation, determined to go abroad for further study along this line, if it could be managed. His classmate, Charles P. Wetherbee (now vice-president and superintendent engineer of the Bath Iron Works), had already entered the French Government School of Naval Architecture at Paris and other friends had gone to Glasgow or Greenwich. The enthusiasm of Homer Ferguson (now president of the Newport News Shipbuilding & Dry Dock Company), who had just returned from Glasgow, made the latter school with its neighboring shipyards on the Clyde appear most attractive and desirable, so Mr. Swan applied himself to the task of raising the necessary funds for this purpose by teaching at the Institute and working during the summer months in the shipyards.

STUDIES NAVAL ARCHITECTURE ABROAD

In 1896, Mr. Swan entered the School of Naval Architecture at Glasgow University, studying under Professor (now

Sir John) Biles. The latter's assistant at the time was Herbert Sadler, now professor of naval architecture at the University of Michigan. Among Swan's classmates were Assistant Naval Constructors Evans, Adams, Robinson and Groesbeck of the United States Navy and Commander (later Rear-Admiral) Fuji of the Japanese Navy. At this time, the late S. F. P. Thearle was one of Lloyd's surveyors at Glasgow and Mr. Swan was fortunate enough to meet Mr. Thearle and to accompany him regularly in his shipyard visits with the result that a warm friendship grew up between the two, terminating only with the latter's death.

After completing the Glasgow courses and receiving the certificate awarded to those successfully passing the final examinations, several months were spent in Professor Biles' office at Southampton, England, working on plans and calculations for various vessels and other similar work undertaken by Professor Biles in his large consulting practice.

EMPLOYED BY LEADING AMERICAN SHIPYARDS

After returning to the United States, Mr. Swan entered the office of Naval Constructor J. J. Woodward, U. S. N., at Newport News, Va., remaining in government employ for the period of the Spanish war. In the fall of 1898 he was employed by the Newport News Shipbuilding & Dry Dock Company as a draftsman and computer. He remained with this company for two years

during which time the Pacific Mail Steamers *Korea* and *Siberia*, the largest ships which up to that time had been laid down on this side of the Atlantic, were designed and the battleship *Missouri*, originally intended for a 16-knot ship, was redesigned for a speed of 18 knots and an increased displacement, practically a new design. With all of this interesting work Mr. Swan was closely associated, the experience gained in Professor Biles' office being of great value, particularly in connection with the Pacific Mail ships.

In March, 1900, Mr. Swan entered the employ of the New York Shipbuilding Company, then just commencing operations at Camden, N. J. He remained in the employ of the company for 17 years, the last five as assistant to the president. From 1909 to 1914 he was largely occupied with foreign work for the company, traveling in Great Britain, Turkey, China, Japan, Russia and South America.

In 1917 the Herreshoff Manufacturing Company of Bristol, R. I., the celebrated yacht building firm, was taken

James Swan

© Harris & Ewing

over by new owners and Mr. Swan was called to the position of general manager of the reorganized company. Here he remained for several years during which time a large and varied amount of war work was carried out. One relatively small item of this work, which nevertheless became famous, was the building of the hull of the flying boat *N-C-4*. In the year immediately following the war a number of fine yachts were constructed at Bristol, but the cost of this class of vessel had become practically prohibitive and the yacht-building business soon was reduced to the construction of launches and small sailing craft.

BECOMES PRESIDENT OF GROTON IRON WORKS

In 1920 Mr. Swan was offered the position of president of the Groton Iron Works at Groton, Conn., and in view of the dullness of the yacht-building business, as well as a strong personal inclination to larger work, he accepted this position. The owners of the Groton plant had rather ambitious plans for its development, but the expected work did not materialize, and, after a year spent in the construction of a steel propeller ferryboat for the city of Boston and some miscellaneous small work, the plant was permanently closed.

GOVERNMENT WORK

Early in 1921, the Ship Sales' Department of the Emergency Fleet Corporation undertook a comprehensive valuation of its fleet and Mr. Swan was called to Washington to carry out this work. It was a task of considerable magnitude and included a detail survey of all the laid-up Shipping Board vessels, about 900 in number. For the survey, a large staff was employed, the actual physical survey occupying about three months' time. The results of all this work are now being tabulated and the final report of survey and valuation is nearing completion.

United American Lines Inaugurate New Coast Service

THE Intercoastal freight and passenger service recently announced by the United American Lines, will be opened by the steamship *Sudbury*, which will sail from Baltimore on September 8 and from New York, September 13. Fourteen modern vessels will operate in a weekly service between Baltimore and New York, Los Angeles Harbor, San Francisco, Portland, Seattle and Tacoma.

The *Mount Clinton* and *Mount Carroll*, formerly in the transatlantic trade, which are now being converted into cargo carriers with cabin accommodations for a few passengers, will be included in the fleet. All the vessels to be used in this service will be over 10,000 tons deadweight, thus making the fleet one of the largest in the intercoastal trade.

The United American Lines have taken over the branch offices in Pittsburgh and Buffalo, formerly maintained by Houlder, Weir & Boyd. Beginning August 27, C. H. Sprague & Son have been acting as agents for the line at Boston and Trosdal, Plant & LaFonta will act as agents at Philadelphia. Branch offices of the line are also located at Baltimore and Chicago. The Pacific coast headquarters will be located in San Francisco, Cal.

CROOK SHIPYARD SOLD.—The municipality of Baltimore is buying the extensive shipyard properties of the Crook Shipbuilding Company, that city, for \$440,000. The property includes a frontage of 462 feet on the harbor and extending back 1,600 feet, a 600 by 80 foot pier with a 565 by 60 foot building thereon, a 320 by 115 foot warehouse of 350,000 square feet floor space, 2,500 feet of railroad sidings, two-story office building, etc. The city will make use of the Crook properties in connection with an expenditure of many millions of dollars for harbor improvements.

Yachts as Naval Auxiliaries

By Norman L. Skene

ONE lesson that should have been learned by this country from the recent war is the usefulness of yachts and yachtsmen in time of war. More than 650 yachts and motorboats were taken over by the Navy and performed highly useful service of various sorts such as gunboats, hospital ships, dispatch boats, coastal patrol, training ships and station boats. It was as training ships probably that the converted yachts were most useful. Knocking around at sea for a few weeks in a small vessel teaches more real seamanship to the raw recruit than months of drill on land or on large vessels.

Yachts of all kinds were taken, even sailing yachts. A few yachts were bought outright but most of them were practically given or loaned to the Government by patriotic owners. Such yachts as were not destroyed or retained by the Navy were returned to their owners very much the worse for their war service.

YACHTSMEN MAKE GOOD NAVAL OFFICERS

A secondary advantage of a large yachting fleet is the potential military value of its personnel. Experienced yachtsmen are the best of material for expanding the personnel of the Navy in time of war and in the World War a great many American yachtsmen demonstrated this conclusively, filling positions of importance in all branches of the Naval service. A yachtsman invariably acquires an intimate knowledge of the handling of boats under various conditions that is the basis of real seamanship.

With the fact of the usefulness of yachts and yachtsmen to the Navy in time of war so recently and conclusively demonstrated, it would seem wisdom on the part of our Government to offer every encouragement to the development of yachting. The present policy of heavily taxing yachts is certainly no encouragement and should be abandoned. The sales tax of ten percent in addition to a substantial annual user's tax added to the excessive cost of building and operation under present conditions are very real deterrents to new construction. Yacht building is at a very low ebb due to above conditions and needs every encouragement. The British Government recognizes the importance of yachts as naval auxiliaries and places no tax on them.

NAVY REQUIREMENTS TOO DRASTIC

It is true that yachts "built according to plans and specifications approved by the Navy Department" may be exempt from taxation but this provision offers no real relief for the requirements are so drastic that few if any yachts will be built in compliance with them. The following are a few of the requirements:

- Length between perpendiculars to be not less than 200 feet.
- To be constructed with watertight subdivisions equivalent to naval practice.
- To have 2,500 miles steaming radius.
- To be capable of carrying an armament of four or more guns of at least 3-inch calibre and four AA machine guns with magazines to carry the standard ammunition allowance.

SUITABLE VESSELS SHOULD BE SUBSIDIZED

It would be good policy not only to exempt yachts fulfilling requirements such as these but to subsidize them as an incentive to build such vessels. The requirements should be ameliorated to include vessels of the size and type of the 110-foot sub-chasers of which so many were built during the war, or even smaller, as one of the lessons learned from the recent war was the value of small fast motorboats even as small as forty-foot length for certain naval uses. The adoption of a policy of encouragement of yachting on the part of our Government involving the abolition of taxes and the subsidizing of certain types would be a very wise move.

Shipping Board Policy Still Unsettled

Division in Shipping Board and Appointment of Advisory Committee by President Prevents Precipitate Action

By Harold F. Lane*

DEVELOPMENTS since the death of President Harding have made it increasingly evident that no precipitate action is likely to be taken to change the present policy of the Shipping Board as to the manner of operating its fleet and with each day of delay the danger that a policy of direct Government operation will be adopted appears to grow less. President Coolidge is yet to be convinced as to either the advisability and practicability or the legality of the proposed plan of operation of the Shipping Board vessels by a group of Government financed subsidiary corporations. As to the legality of the plan, he expects to ask an opinion of the Attorney-General and as to the merits of the plan in general he is thinking of seeking advice from outside of the board by the appointment of a special committee consisting of the Chairman of the Shipping Board, the Secretary of Commerce, the Secretary of the Treasury, the chairmen of the Senate and House committees having merchant marine affairs in charge and possibly one or two others, to study the question.

This was officially announced at the White House on August 21, following several conferences between President Coolidge and Chairman Farley and other members of the board. The President does not, however, consider the plan of operation through subsidiary corporations, of which the stock would be owned by the Government, amounts to "direct" Government operation in any technical sense and is represented as referring to it rather as "indirect" Government operation, but he has also made it plain that no change in the present plan is likely to be adopted without careful consideration, although he is hopeful that some plan can be devised to reduce the present losses.

SUBSIDIARY CORPORATIONS, LASKER'S PLAN

The subsidiary plan has heretofore been generally referred to as providing for "direct" Government operation by former-Chairman Lasker, President Harding and Chairman Farley. It has also come to be referred to frequently as the Lasker plan because in his letter of resignation to President Harding, Mr. Lasker said that, with the failure of the subsidiary plan, and if the ships could not be sold by the board on favorable terms, the only apparent alternative is to "go the full length of direct Government operation" and he recommended the creation by the Emergency Fleet Corporation of 12 to 18 subsidiary corporations. President Harding had also expressed general approval of this idea in a speech in which he said that direct Government operation would be "aggressively pursued," if that turned out finally to be the only alternative.

Some significance in this connection has been attached to the announcement by President Coolidge that he intended to carry out the policies of his predecessor in office, but he has also indicated that this statement applied "in general" and that the policies might necessarily be subject to such changes as President Harding himself would have made if he had lived. Moreover, so far as known, President Harding had never specifically approved any definite plan of Government operation and it is well known that he frequently condemned the principle of Government operation, viewing it only as a final alternative. As no definite feasible substitute for the present system of operation was laid before

him, it can hardly be said that President Coolidge is in any way committed.

Moreover, there is a sharp division in the Shipping Board itself as to the plan which should be adopted. Sanction to the plan of subsidiary corporations was given by a bare majority when a vote was taken about August 1, it is learned, Chairman Farley and Commissioners O'Connor, Thompson and Lissner voting in approval, while Commissioners Benson, Plummer and Haney recorded their opposition. No official announcement has ever been made of this fact nor have the details of the plan been made public.

Chairman Farley of the Shipping Board on August 16 submitted to the President a detailed written report covering the views of the board as to what ought to be done and it was later stated at the White House that several statements on the subject were before the President and would have careful consideration before a decision was reached as to what, if any, changes should be made. Chairman Farley also had another conference on the day before the announcement of the proposed appointment of a committee. Commissioner Plummer, who is one of those opposed to the plan, has also presented his views to the President. Chairman Farley had also stated that the Government would not put a new shipping plan into effect until after representatives of the shipowners' and ship operators' organizations had had an opportunity to present alternative plans. It is understood that the details of the plan voted on were prepared by the special committee, composed of Chairman Farley and Commissioners O'Connor and Thompson, appointed on June 4, and were based on the recommendations of Mr. Lasker in his letter of resignation.

DIRECT OPERATION, ALTERNATE PLAN

Commissioners Plummer and Benson are reported to favor methods of direct operation which will give the present operators an opportunity to secure freight for the board's vessels on a commission basis, but which would leave them no part in the handling of the boats. Commissioner Haney is said to regard direct operation of any character as permissible only as a last resort. It is also understood that while Commissioner Lissner is in favor of the subsidiary plan for those operations conducted by the Government, he still is in favor of making every effort to sell as many of the lines as possible for private operation. The claim made for the subsidiary plan is that it would be much easier to sell a line as a going concern with its good-will, organization and terminal facilities, by the transfer of a certificate of stock than to sell simply a certain number of ships for operation on a line where the good-will and going concern features are under the control of the managing operators.

The position of the minority was that the proposed transfer of the ships to subsidiary corporations would involve a delegation of the trusteeship of the Emergency Fleet Corporation which would be illegal, and also that the plan would be impracticable. They insisted at least on an opinion from the Attorney-General as to the legality of the plan, although the legal department of the Shipping Board is said to be of the opinion that it is legal.

OWNERS AND OPERATORS CONFER WITH BOARD

Representatives of the shipowners and operators were given an opportunity to present alternative plans at a conference

*Our Washington correspondent.

with members of the Shipping Board at Washington on August 28. This conference was originally set for August 21 but was postponed at the request of the shipping men. One plan proposed by the American Steamship Operators' Association was formally rejected by the Shipping Board after a long session on July 24. Chairman Farley issued a statement saying that the plan proposed that the board deliver to the operating companies the needed vessels to maintain service on the present established routes for the absolute control of the operating company without board supervision, the board to pay the expenses and any losses and the profits to be set aside in a special fund for the use of the operators to buy ships from the board. This, he said, "has all of the inherent defects of the present M. O. 4 contract which is to be abandoned, and adds a number of other objections." He added that the board hoped to be able shortly to make a definite statement of the plan for direct operation on which it was working.

Later the operators' association made public a formal statement protesting against direct Government operation of ships and saying that such a policy would bring about complete failure of the efforts authorized by Congress to develop a privately owned merchant marine. Further correspondence brought forth letters from Mr. Farley to the Steamship Owners' Association and the Ship Operators' Association stating that while the board had fully considered their proposals it would be glad to discuss the situation further with them at any time and the arrangement for the new conference resulted. In these letters Mr. Farley referred to two of the objections to the proposed plans as follows: "Your plan provides no supervision and control of the expenditure of Congressional appropriations, and in addition contemplates the establishment of a sinking fund to be carried over a minimum of three and a maximum of six years. Manifestly, both or either of the above provisions are impossible of execution under the present law."

U. S. CHAMBER OF COMMERCE OPPOSED TO GOVERNMENT OPERATION

A committee of officers of the United States Chamber of Commerce called on the President on August 20 to put before him the position of American business on important economic questions and on the subject of the merchant marine told him that the chamber is opposed to the Government engaging in commercial business. It believes that further efforts should be made to evolve a plan of operation by private citizens before entering upon Government operation. The chamber favors the ship subsidy in the effort to equalize operation disadvantages of American ships and it has asked an investigation of the possibility of relaxing the burdensome restrictions.

American Marine Congress Grows Bigger and Bigger

NO better indication of the interest that is being taken in the all-American Marine Congress which will be held in New York during the week of November 5-10 could be desired than the long list of representative organizations who will cooperate, printed below. That which is needed above everything else is a definite expression of facts and findings that will represent the non-partisan opinion of all sections of the country on what ought to be done to establish our merchant marine.

ORGANIZATIONS COOPERATING TOGETHER WITH NAME OF CONTACT REPRESENTATIVE

American Manufacturers' Export Association, Myron W. Robinson; Council of American Shipbuilders, Homer Ferguson; American Steamship Owners' Association, Winthrop L. Marvin; United States Ship Operators' Association, Charles H. Potter; New York Tow Boat Exchange, Fred B. Dalzell, Jr.; Neptune Association, Capt. John F. Milliken; National Board of Steam

Navigation, N. L. Cullen; Lake Carriers' Association, William Livingston; National Marine Engineers' Beneficial Association, William S. Brown; Ocean Association of Marine Engineers, T. A. King; New York Boat Owners' Association, William H. Kelley; Hudson River Improvement Association, Clarence R. Birkett; South Atlantic States Association, Matthew Hale; Atlantic Coast Shipbuilders' Association, Clarence S. King; Maritime Association of the Port of New York, John Dowd; American Marine Association (Officers and Executive Committee); Society of Naval Architects, Captain C. A. McAllister; Charleston Chamber of Commerce, Charleston, S. C.; American Society of Marine Designers, C. C. Jacobson; Propeller Club; American Association of Advertising Agencies, James O'Shaughnessy; The National Association of Cotton Manufacturers, Henry C. Meserve; American Bureau of Shipping, Capt. C. A. McAllister; United States Navy; City of Buffalo, N. Y., Mr. Frank X. Schwab; The Railway Car Manufacturers' Association, W. F. Goss; National Merchant Marine Association, Henry C. Wiltbank; American Society of Naval Engineers, Rear Admiral C. W. Dyson; United States Producers' Association; Chamber of Commerce of the United States; United States Shipping Board; The Commission of Public Docks, of Portland, Ore.; G. B. Hegardt; City of New Orleans, La., Mayor A. J. McShane; City of Detroit, Mich.; American Association of Engineers, Fred Lavis, A. Knowles, and I. C. C. Cooper; National Association of Credit Men, Edward P. Tuttle; American Engineering Standards Committee, A. W. Whitman; United States Department of Commerce; National Paint, Oil & Varnish Association, Harry J. Schnell; The American Legion, E. E. Spafford; Ohio Chamber of Commerce, George Carey; Detroit Board of Commerce, Charles E. Boyd; American Marine Standards Committee, Capt. R. D. Gatewood; City of Newark, N. J., P. H. W. Ross; American Institute of Mining and Metallurgical Engineers, Philip W. Henry; City of Portland, Oregon, Mr. George L. Baker; The Port of New York Authority, Eugenius H. Outbridge; Lorain Chamber of Commerce, Lorain, Ohio, G. W. Dudderar; Harbor Department City of San Diego, Cal., J. W. Brennan; National Safety Council; Madison Association of Commerce, Madison, Wis., Don E. Mow; Minneapolis Civic & Commerce Association, Herbert M. Gardner; Mid-West Farmers' & Manufacturers' Conference, Malcolm Stewart; Fidelity Marine Association of Masters and Mates, Capt. N. L. Proctor; American Fair Bureau Federation, O. E. Bradfute; Committee of Manufacturers on Standardization of Valves and Fittings; Passaic River Improvement Association; Edw. B. Lyman, Director; New York Freight Forwarders' and Brokers' Association; Savannah Board of Trade, Savannah, Ga., Devereaux Bacon; Cincinnati Chamber of Commerce, Cincinnati, O., Malcolm M. Stewart; City of Camden, N. J., Hon. Victor King, Mayor; International Association of Machinists, Alfred Peabody, Joseph L. Maxwell, Julius Meyers, George Rolph, John F. Dalton; City of Wilmington, Del., Hon. George W. K. West; Portland Steamship Operators' Association, Frank Ira White; City of Philadelphia, Pa.; Hon. J. Hampton Moore, Mayor; City of Trenton, N. J.; City of Chester, Pa.; City of Pittsburgh, Pa.

Standard Oil Tugboat Launched

SOCONY NO. 9, the second of two steel single screw tugboats building at the Tebo plant of the Todd Shipyard Corporation for the Standard Transportation Company, New York, was launched on August 6.

These tugs are to be equipped with vertical, compound surface condensing engines with cylinders 18½ and 40 inches diameter by 26 inches stroke, designed for a speed of 12 revolutions per minute, built at the Todd plant at 742 E. 12th Street, New York. The boilers will be three-furnace Scotch marine, 14 feet 9 inches inside diameter and 12 feet long, with a grate area of 75 square feet, a heating surface of 2,700 square feet and a working pressure of 160 pounds per square inch. Todd fuel oil burners will be installed.

The dimensions of the boats are: Length overall, 105 feet 9 inches; length between perpendiculars, 100 feet 5 inches; breadth molded, 24 feet; depth molded, 12 feet 9 inches; draft loaded for sea, 10 feet 6 inches, forward; 12 feet, in salt water.

New York Central Buys Weehawken Piers

THE Cunard Steamship Company has resold the 800-ton pier, K-44, south of the West Shore ferry terminal at Weehawken, N. J., to the New York Central Railroad Company, and also the old D. and H. coal dock, at the same Baldwin Avenue, half a mile south of the pier, to the same company. The latter will be remodeled and the railroad company will use both as freight piers. Former piers of the Cunard Line in connection with this development have been dropped.

"Homer" and "Joe"—Master Shipbuilders

A Résumé of the Accomplishments of Two Outstanding Leaders in the Shipbuilding Industry

By "Old Scotch"

NOW that those of us in the shipping business have, by force of circumstances, time to cogitate over the past, present and future it is well to glance back a few years and consider some of the remarkable feats performed in the great shipbuilding boom which we passed through as an incident of the Great War.

Important industrial accomplishments, such as the completion of this greatest shipbuilding feat of all time, cannot be carried on without developing or utilizing some outstanding men, as the personnel is bound to be reflected in the outcome of any human undertaking. Our shipbuilding facilities of pre-war years were "naturally" quite limited both as to physical equipment and personnel. Of this limited personnel all of them proved their mettle and became leaders among the thousands and thousands of men from all walks of life who rushed to the shipyards, in answer to the nation's call.

The leaders of the pre-war shipbuilders quite naturally became the super leaders of the greatly expanded industry, during and just following the fevered activities incident to so vast an undertaking, which involved the investment of the stupendous sum of over three and a half billions of dollars in yards and ships.

TWO OUTSTANDING LEADERS

Without disparagement to many other leading characters in this great work, we can all agree that two of the outstanding men in the great rush were Homer Ferguson of the Newport News Shipbuilding and Dry Dock Company and Joe Powell, the man in direct charge of the vast shipbuilding activities of the Bethlehem Shipbuilding Corporation.

Few there are among the large armies employed in the wartime shipyards, who did not know these two men either personally or by reputation; hence the title of this brief résumé of a "close-up" of these personalities.

Joe Powell, a born-and-bred New Yorker, and Homer Ferguson, a product of the old North State, have much in common, although representing the old civil war division of the country, the North and the South. Both were blessed with comely countenances, genial dispositions, the faculty for making friends to a marked degree, brilliant minds and unbounded energy. Both were educated under the tutelage of Uncle Sam at Annapolis, and both received that distinctive reward of scholarship, appointments to the Navy Construction Corps, which in common with the Engineer Corps of the Army brands the wearers of the insignia of their respective corps, as men of the highest scholarship and attainments.

AMERICAN MERCHANT MARINE, THEIR RELIGION

Both had the foresight, energy and opportunity to sever their connections with the Government, before advancing years and accumulated "fogies" had lulled their ambitions to a state of lethargy. Both absorbed the business acumen necessary for positions of great responsibility in a remarkably short space of time, and both with equal fervor made the advancement of everything that pertains to a strictly American merchant marine not only a hobby but a religion. When the time came for great accomplishments in their chosen profession they were on the job and not lacking a single attribute, physically or mentally, to make a success of the huge responsibilities which were to fall to their lots.

Through the lamented loss of President Hopkins on the

Lusitania, his mantle fell on the capable shoulders of Homer Ferguson, who had by that time worked his way up to the vice-presidency of the great Hampton Roads plant.

Joe Powell had gone from the position of assistant to the president of the William Cramp and Sons Ship and Engine Building Company to the presidency of the Fore River Ship and Engine Company, and, upon Mr. Schwab obtaining control of this concern and merging it with five other yards, he quite naturally placed the entire shipbuilding branch of the Bethlehem company under the direct charge of the hustling young executive, whose services he had obtained with the Fore River yard.

With such important positions of responsibility these two men began what was to be the most serious work of their lives—the fulfillment of the enormous demands for ships which were placed on these respective establishments. Equipped as both were, there was no chance of failure—success for their efforts was foreordained. From early in 1917 until the completion of the wonderful output of both naval and merchant vessels in 1920, it is doubtful if there were two busier men on earth than this same Homer and Joe. Back and forth to Washington, the seat of government, where their services and advice were almost constantly in demand, this busy pair were almost like shuttlecocks. Everywhere they went they radiated encouragement, spirit and "pep" to their assistants and to the officers of the Government who were demanding more than the capacity of the yards under their control.

Some one asked Joe Powell his permanent address during those troublous days, and his reply was the "Hotel Pullman," and indeed there were very few days that he was not contributing to that perambulating hostelry in his frequent trips between Bethlehem, Boston, New York, Wilmington, Baltimore, Washington, San Francisco and others places, attending to the various ramifications of the largest private shipbuilding organization the world has ever seen.

A CONVINCING SPEAKER

If any one could have guessed Homer Ferguson's whereabouts on any particular day in the future, he would have had to be gifted with second sight. If any week passed during the entire war when Homer was not wanted on some committee work in either Washington or New York, it has not been recorded. You see, Homer among his other attributes had obtained wide fame as a speaker. As one of his colored employees expressed it, "Mr. Homer certainly am the convincinest man"—a natural tribute to his skill in dealing with his workingmen, the majority of whom are and have always been descendants of Ham.

The story of how he "got that way" is quite interesting. Early in his shipbuilding career he had quite a local reputation as a speaker at launching banquets, church socials and other community gatherings. Some of his friends hearing of it, decided to try him out at the annual banquet of the American Society of Naval Engineers, an affair which, held at Washington, usually attracted some of the best post-prandial speakers from Congress and the Department. On the night of Ferguson's debut, and first appearance in the Big League, it so happened that the question of building battleships at Navy Yards in competition with the private yards was acutely in the public mind. Among the congres-

sional speakers was the Hon. John J. Fitzgerald of Brooklyn, who could not see much good in any naval appropriation, wherein his pet Navy Yard was not recognized. "Fitz," as he was known, was even then a very important member of the Appropriations Committee, and, as a general all-around debater and parliamentarian had few equals on the floor of the House. "Fitz" and "Fergy" locked horns at the drop of the hat, and the banqueters were treated to a debate which has long been remembered. The recruit from the Newport News Bush League of Oratory did not come off second best by any means, as Fitzgerald closed his remarks by saying, "If Mr. Ferguson builds ships as well as he argues, I have no fear for the future of our Navy."

Subsequently, Ferguson made his initial address at the banquet of the American Society of Naval Architects at the Waldorf in New York. A certain cabinet officer opined that all that American shipyards needed, was to build standardized ships, to meet overwhelming success. This aroused Ferguson's ire, and the way that he bowled over the cabinet officer's arguments has become a classic in the Society. Since these two events Homer has obtained a nation-wide reputation as a public speaker, a reputation which eventuated to a large extent, in his being elected president of the United States Chamber of Commerce.

AN ABLE CONGRESSIONAL WITNESS

A thorough knowledge of his subject, and a most convincing manner of presentation makes Homer Ferguson one of the ablest witnesses who ever appears before a Congressional Committee. During the early stages of the war, when everything seemed to be going to the bow-bows abroad, and nothing seemed to be able to start at home, Ferguson appeared before a Senate Committee to get money enough to start a housing proposition, necessitated by the vast increase of war workers in Newport News. Delays and visiting around the departments had nearly driven him to distraction. Hence when he appeared before the solons on the Hill, he was in a fine state of mind to state the needs of the hour. When Homer is deadly in earnest his eyes have a faculty of weeping to emphasize his seriousness. On this particular occasion several of the older senators became so impressed with his statements that they too wept with the witness. The chairman was so overcome with emotion that he did something never before heard of in the annals of legislation. At the climax of Ferguson's appeal the presiding officer said very solemnly: "Mr. Ferguson, if you can stay in Washington for 24 hours, I'll appoint a sub-committee to go with you to the housing officials and see that you get the money to start this proposition at once."

Ferguson stayed, and the money was made available in four hours.

Joe Powell accomplished great things during the war; although he does not possess the eloquence of Homer, his business rival, he has other ways of putting things across. Added to his winning personality there is a persistency of purpose in Powell's make-up that usually lands the bacon. This is best illustrated by an incident in his career which occurred after he had withdrawn from his shipbuilding activities. Let it be said here that our much-beloved and lamented President Harding knew both Homer and Joe and knew them well. Either one of them could have been Chairman of the Shipping Board if they would have accepted that position from the President.

Finally President Harding in his very persuasive manner, succeeded in getting Joe Powell to serve as president of the Emergency Fleet Corporation for a brief time. He consented to do this without pay, but, as the law prevents any one from serving the Government for nothing, he had to take \$1 per month. His first month's pay check was mounted in a frame and used as a paper-weight. As it cost him \$3 to have this \$1 check mounted, Joe allowed it was rather an uneconomical proposition.

THE LEVIATHAN

It was during his brief incumbency of this job that he conceived the idea of reconditioning the *Leviathan*, then rapidly deteriorating at her Hoboken dock. He satisfied himself that it would be a paying proposition and, with the approval of the President and the Chairman of the Shipping Board, he tackled the job in typical Powellesque manner. If any one thinks this was an easy task, just let him recall the bitter fight made by Powell's best friends in Massachusetts to have the reconditioning done in the Boston Navy Yard. Threats and entreaties availed not, as Joe was firmly convinced that the job could be done for less money and in less time at a private yard. How well it was done and how successful the large ship is panning out are facts too recent to need repetition here. By the way, in all the press acclaim of credit for this splendid reconditioning job has any one heard Joe Powell's name even mentioned as having had anything to do with it? I haven't!

Throughout the long trying months of the war these hustling shipyard leaders kept up the pace and delivered ship after ship to a world whose principal need at the time was ships, ships and yet more ships. Their earlier training, both physical and mental, stood them in good stead, and they were able to withstand the terrible pressure put upon them. Both are yet in the prime of their lives, and, if shipbuilding does not offer sufficient employment for their boundless energies, they may have to go into other lines of effort. Homer Ferguson is trying to get enthused over building box cars and automobile wheels at the Newport News plant, but he admits that anything that floats is much more attractive to him.

Perhaps this idea of "anything that floats" may account for the besetting sin of both Homer and Joe. I had almost concluded not to give these great men away as to their weaknesses. Strange to say they are both afflicted with the same shortcoming, so as a matter of candor to the readers I will have to divulge it. Its "ducks, ducks and yet more ducks" that afflicts them both. This may be and probably is because ducks float and can go through the water rapidly. However, it is well known to the intimate friends of both these men, that if either Homer or Joe should hear a duck quack or a wild goose honk, even while those shipbuilders might be negotiating a contract they would both instinctively grab a suit-case and a shot gun, and beat it for the nearest blind. When they would meet, as they formerly did quite frequently, it was not "how many keels have you laid?" but "how many 'red heads' or 'canvas backs' did you bag on your last trip to the island?"

SELF-DISCHARGING BARGE.—A novel type of tipping barge in which, by means of trimming tanks, a deck cargo consisting of about 300 tons of quarried stone may be automatically discharged to either side of the craft, was recently shipped to West Africa. It forms one of four such barges which will be used in connection with the building of a new breakwater at Takoradi by Stewart and McDonnell for the Crown Agents for the Colonies. These vessels were built at the Lytham Shipbuilding and Engineering Company, Limited, their construction and the tests on them being carried out by Flannery, Bagallay and Johnson, Limited, of London. The trimming tanks are arranged along either side and are divided into four by three transverse bulkheads. The design is so carried out that the bottom of the tanks is higher than the flotation level when the vessel is light. When loaded with deck cargo the ship is taken to the dumping site and sluice valves are opened, which admit sea water to the tanks on the side it is desired to discharge from. The barge is thus automatically careened to such an angle that the deck cargo is shot overboard, and, relieved of the weight, the vessel rises and empties the tanks.

—The Engineer.

Efficiency and Economy in Traffic Work

By Herbert Sheridan*

NOW that the country has assumed its stride and trade conditions generally have greatly improved, the obstacles that lie in the path of satisfaction are interwoven with efficiency in traffic and transportation matters, or the lack of it. The prompt and dependable movement of traffic between producer and consumer assume even larger than normal proportions. The plant expects prompt receipt of raw materials, the jobber looks for prompt movement from the mills, the country merchant wants to get his purchases without delay. All these interests include the welfare of communities that are affected when completion of public works is delayed.

Campaigns for "safety first" have accomplished much. Campaigns for prevention of claims have always produced gratifying results; but there is still much to be said and much more to be done in the way of driving the lesson home to a great many people who have not seen the vision of quicker returns on capital, greater satisfaction to customers and lessening of exasperating incidents, because common sense methods are not more generally used in getting traffic under way and properly safeguarded.

Fortunately, there has been a noticeable improvement in the plan of having a specific department take care of receipts of materials and merchandise and a shipping department more or less well equipped to insure the proper marking, billing and routing of valuable property, for which the traveling man has incurred expense and frequently secured under adverse conditions. Generally there is a lack of care in suitably preparing property for shipment. There is room for improvement in the sorting of articles, so that the classification will be observed and, when possible, articles of the same classification put into the same package. There should be a more general custom of packages containing slips, showing the name of the shipper as well as the name of the consignee.

STENCILS SHOULD BE USED FOR MARKING

The outside marking would be much more legible, if stencils were used, and although receiving agents are instructed to insist on shipments being properly marked, it is a lamentable fact that many shipments still go astray through lack of sufficient and thorough marking. Shipping orders and bills of lading should be made out on the typewriter when possible, for the sake of legibility. The one in charge of shipping should know what system of package cars prevails and so time his shipments that these can be used.

Consignees could materially aid themselves and many other interested people, carriers, producers and consumers by a much more prompt removal of property from the terminals on arrival instead of allowing terminals to be cluttered up with continued receipts of shipments.

The word "service" has come into strong play, and nowhere is it more needed than in the entire transportation game. When each man has a considerate regard for the

other and is willing to be informed about some of the difficulties that transportation companies have to contend with, in order to supply the desired service, and will give special heed to the suggestions as to his part in the desired betterment, there will be a decrease in the cost of operation and a noticeable improvement in the service the transportation companies strive to give.

TRAFFIC CLUBS

One of the most beneficial things that has come about lies in the formation of traffic clubs, wherein through membership in an organization composed of railroad men and those engaged in the manufacture and distribution of merchandise, many vital subjects are spread out for review, consideration and betterment. A spirit of tolerance has been developed, because through these traffic clubs, there has been maintained an increased knowledge of some of the hardships that are peculiar to the subjects of traffic and transportation. There are also organizations of standing that are imparting instruction about these subjects; among the most prominent is the LaSalle Extension University of Chicago. This organization has a large staff of instructors, competent to impart much valuable information and it has the endorsement and friendly regard of a number of prominent officials in the traffic field.

All that is said about some of the inland difficulties apply with equal force to the constantly growing coastwise steamer traffic. Many shippers are anxious to determine which is the better way to reach their remote customer, that is, whether to send shipments to the Atlantic seaboard for movement through the canal, thence to a Pacific coast port and by rail to an inland point; or ship all-rail as heretofore. Fortunately, tariffs are available that define the classifications applicable, the rates in cents per one hundred pounds, the transfer and other terminal charges at ports and rates to the interior, so that the uncertainty as to comparison of cost can soon be removed. Other coastwise steamer service involves a knowledge of service rendered by the different companies, schedules of their sailings, tariffs showing rates between interior and coast ports, as well as port to port rates. Specific information, including the subject of insured rates, can always be obtained from the nearest representative of the various lines. Water transportation is receiving more and more attention, and very properly so, because with the rapid growth of our country, railroad building has not kept pace with developments. Increased reliance has been placed on water movement, which has reacted greatly to the advantage of many sections of the country.

GYRO-COMPASS COURSE FOR BRITISH OFFICERS.—Owing to the growing importance of the gyro compass in the navigation of modern ships, every British naval officer who has qualified in the navigation of first class vessels is required to go through a gyro-compass course of two weeks' duration at the Admiralty Compass Observatory, Ditton Park, Langley, Bucks. Those that have had gyro instruction are required to take refresher courses at intervals of three years.

New Wilson Line Excursion Steamer State of Delaware

Two Excursion Steamers Built for the Wilson Line

**New System of Construction Increases Strength and Reduces Vibration —
Features Introduced for Safety, Comfort and Entertainment of Passengers**

TWO new excursion steamers, the *State of Delaware* and *State of Pennsylvania*, plans and specifications of which were prepared by the George G. Sharp Company, naval architects and consulting engineers, 30 Church Street, New York City, have recently been built by the Pusey & Jones Company, Wilmington, Del., for the Wilson Line of Wilmington and placed in operation on the Delaware River.

The addition of these two new steamers to the line have enabled the management to provide a much more frequent schedule between Philadelphia, Riverview Beach and intermediate points. Two and one-quarter hours are consumed in the Riverside Beach run, a distance of about thirty-five miles, each vessel making two round trips per day and in the evening a moonlight excursion down the river from Philadelphia.

The Wilson Line's policy is to keep their regular passenger fleet up to date by the addition from time to time of new vessels specially adapted to their requirements and embodying the latest developments in the field of naval architecture. Their steamers have invariably been in advance of their time, and it is already apparent that the latest additions to the line fully maintain the reputation and traditions of the company. The long experience and intimate knowledge of the service made available to the architects by Captain Horace Wilson and Mr. J. S. Wilson of the Wilson Line has resulted in a design being developed which marks a distinct advance in the economics of operation and structural design.

NEW TYPE OF CONSTRUCTION INTRODUCED

Since the conditions of service limited the extreme length of these vessels to 225 feet it is obvious that the difficulties attendant upon providing ample space, unobstructed vision and means of entertainment for 3,500 passengers in a comfortable atmosphere were not inconsiderable, nor would they have been overcome by reproducing the type of excursion steamer to which we have become accustomed. The means whereby results have been achieved are of interest by reason of the advance they mark in the methods of construction.

Instead of adopting the usual method of superimposing one deck upon another a new system of trussed lattice framing was developed whereby all the structural members from the bottom of the hull to the uppermost superstructure deck were assembled into a single rigid unit. The resultant structure is as solid and free from vibration as the superimposed type is conducive to this source of discomfort so frequently met with in passenger steamers of light construction.

Although these two vessels have equal capacity to the combined regular fleet of four vessels in the Wilmington-Philadelphia service, their daily fuel consumption in service, it is reported, has shown an economy of over thirty-five percent when compared with that of the original fleet.

STRUCTURAL ARRANGEMENT

The hull is constructed on a special system of trussed lattice framing, consisting of wide spaced deep frames and beams up to the first superstructure deck with steel tie beams at each of the superstructure decks above, combined with continuous columns run from the main frames or deck beams to the uppermost deck of the superstructure. These columns are in one piece, or efficiently jointed as may be necessary for loading or other local conditions, and along with the diagonal members are riveted at all intersections of beams, frames or floors. The complete frame units were erected and regulated ready to receive the intermediate frames and fore and aft steel girders. When these had been erected the intermediate beams and carlins of the superstructure decks were erected, thus permitting the construction to proceed on all or as many decks as was found desirable.

It should be noted that the familiar guard braces have been dispensed with, the truss construction of the main framing satisfactorily supporting the overhanging sides of the main deck.

The shell plating is overlapped at the butts and seams, but the main deck is laid flush to receive Rubberstone decking with which it is covered.

The boiler casing is of steel extending to the boat deck

General Data: New Wilson Line Excursion Steamers

General Information		Life Saving Equipment		Feed water heater—1, No. 16, Reilly Type G.	
Service: Delaware River and Bay Excursion Service.		No. Type Length Capacity		Fuel oil heaters—3, 12" x 50", Coen.	
Builder: Pusey and Jones Company, Wilmington, Delaware.		Lifeboats 6 Steel 24—0 41		Pumps:	
Owner: Wilson Line, Wilmington, Delaware.		Working boats 1 Steel 16—0 —		Circulating—1, 12" suction, 10" discharge, 9" x 9"	
Characteristics		Life rafts 4 Steel 21—0 34		Engberg Eng., Pusey & Jones Co., fan pumps.

and is insulated to the height of the observation deck. The engine room is open, having a steel casing around the hatch extending to a height of about three feet above deck.

The hull below the main deck is subdivided by five transverse steel bulkheads into six watertight compartments as follows: Fore peak, forward compartment, boiler room, engine room, after compartment and after peak. The fore peak is arranged for the carriage of reserve feed water.

CREW

In the forward compartment on the lower deck is arranged the kitchen, pantry, ships' provision and refrigerated

rooms and mess room, while below the lower deck are the culinary fresh water tanks. In the compartment abaft the machinery space, accommodation is provided for the engine, deck and steward's department crew.

Above the main deck, with the exception of space occupied by the pilot house, officers' quarters and life-saving ap-

pliances on the boat deck, the remainder of the vessel is arranged for the accommodation of the passengers, 3,500 being the complement. There are four decks in all, viz.: main, saloon, observation and boat decks. Ample seating capacity and comfortable deck space is provided for all passengers and terraced observation decks ensure a perfect view, light

Enlarged Plan of Machinery Space

and ventilation for everyone on board regardless of their location.

With the exception of enclosures around the forward stairways and the refreshment booth on the saloon deck the sides are all open and fitted with rails only. Protection from the weather, when necessary, is provided by means of canvas drop weather screens fitted completely around the vessels.

The central portion of the saloon deck is reserved for dancing. The floor is approximately 35 feet by 90 feet without obstruction of any kind other than a bandstand, which is centrally located. The terraced decks over this part of the vessel give additional height which is about 12 feet at the center and 10 feet at the sides.

REFRESHMENT BOOTHS

At the forward end of the saloon deck there is a large refreshment booth enclosed, along with forward stairways, within a glass weather screen, while on the main deck aft a similar refreshment booth is fitted. The furnishing of these booths is most complete, and their 165 feet of serving counter provides adequately for the passengers' service without the attendant discomfort so frequently experienced due to crowding and delay.

At the forward end of each booth are plate glass and mahogany display cases fitted flush with the sides of the booth and blending with the mahogany sides and serving counter of the booth proper.

STEERING, NAVIGATING AND HANDLING APPLIANCES

Steering.—A partly balanced rudder of the double plate type is fitted with an extension stock carried to the boat deck where an emergency steering gear has been arranged for controlling the tiller through tackle connected to a drum operated by a hand steering wheel. The main quadrant is fitted on the rudder stock at the under side of the main deck having direct leads to the steering engine in the after engine room by means of rods and chains. The steering engine is operated by a wheel in the pilot house through the usual mechanical shaft control which is carried along the boat deck and down the engine room ventilator to the steering engine. The steering engine is of the American Engineering Company's 6-inch by 6-inch, two-cylinder, steam-driven drum type.

Windlass and Anchors.—The windlass, which is located on the main deck, is of the double vertical type driven electrically by a $7\frac{1}{2}$ horsepower, 125 volt, direct current, General Electric motor through spur and worm gearing. The motor and gearing are mounted on the same bedplate on the deck below and drive the two wildcats and capstan on the deck above through vertical shafts.

There are two stockless anchors of 1,050 pounds each housed on bevelled skids ready for release and 90 fathoms of 1 $\frac{1}{16}$ -inch stud link cable.

Capstan.—There is an electrically driven capstan on the main deck aft actuated through spur and worm gearing by a $7\frac{1}{2}$ horsepower, 125 volt direct current General Electric motor. The motor and gearing are on one bedplate attached to the underside of the main deck driving the capstan barrel above through a vertical shaft.

Mooring Bitts.—There are six mooring bitts on each side and one on the center line aft, making thirteen in all. These are of a special type made of bronze and mounted on top of the bulwark rail.

Signal Mast.—A signal mast is fitted amidship, carrying a signal yard and range light. A head light is fitted on the stem head with the port and starboard running lights at the sides of the navigating bridge.

Communication.—Communication to the engine room is by the usual inland mechanical bell system. Communication by speaking tube with mechanical call bells is also provided from the pilot house to the engine room.

APPLIANCES FOR SAFETY AND LIFE SAVING

Subdivision.—The main hull is divided transversely into six watertight compartments, there being five complete steel watertight bulkheads to the height of the main deck and two steel longitudinal watertight bulkheads from the top of the floor level to the lower deck, forming deep tanks for fresh water.

Life Saving.—On the boat deck there are six 24-foot metallic lifeboats and four large life rafts, with a working boat on the main deck forward. The lifeboat capacity is considerably in excess of the requirements of the service and Steward patent mechanical davits have been installed to insure prompt and efficient handling of the lifeboats in an emergency.

Life preservers are supplied for all on board. These are stowed between the beams on the under sides of the three upper decks along the sides of the vessel and are capable of being instantly released in an emergency. Cords are run fore and after through the beams and suitably spaced to provide two cords for the support of each row of life preservers. At the end of each row these cords are brought together and made fast on cleats so that by releasing the cords any row or rows of preservers instantly fall to the deck.

There are also stowed in convenient locations twelve cork ring life buoys, six of which are of the self-igniting luminous type.

Fire Prevention.—In the matter of fire prevention every precaution has been taken by the use of fire resisting materials eliminating wood as far as practicable. The whole superstructure is framed completely in steel. The main deck along with the machinery and boiler casings is completely of steel while the cabin enclosures and their internal bulkheads are constructed of Plymetal as manufactured by the Haskelite Corporation. There are several types of Plymetal, but that used on these vessels is of the double-faced type, which is a combination of Plywood and steel composed of a three-ply panel to which is added two faces of thin double galvanized stretcher leveled sheet steel.

While every effort has been made in the construction of these vessels to make them fire resisting, the most modern and effective means of fire fighting have been adopted to meet any emergency. In addition to the regular water fire system with outlets and hose at suitable points throughout the vessel a number of patent tanks have been installed, each containing water or a chemical supply for the first six fire buckets contained therein.

A further precaution has been taken by the installation of a Foamite hose pressure system in these vessels. The system consists of two riveted steel tanks, having a capacity of 300 gallons of solution each, from which separate pipes are led to Foamite hose stations located on the starboard side of the boiler room, on the forward bulkhead on the starboard side of the engine room and on the bulkhead of the boiler casing on the main deck. The solutions are expelled from the tanks by nitrogen under a pressure of 40 pounds per square inch. Seamless drawn steel cylinders are used as containers to hold this nitrogen at a pressure of 2,000 pounds per square inch. The cylinders are connected by means of flexible couplings to a high pressure manifold located in the engine room near the fireroom entrance door and the main control valve for the operation of the system is installed at this manifold. Gages are fitted to both the high pressure and the low pressure sides of the manifold, as well as on each solution storage tank. An arrangement of valves has been provided, so that the system may be readily flushed out with water; and charged after it has been used.

REFRIGERATING PLANT

The refrigerating plant consists of the following:

1 Remington Machine Company 5-ton unit compressor, having cylinders $4\frac{1}{4}$ inches diameter by 9 inches stroke, the engine having a diameter of 7 inches and a stroke of 7 inches. Both the engine and compressor are on the same base.

1 Liquid ammonia receiver.

1 Ammonia condenser 12 feet long by 19 pipes high.

2 Warren duplex vertical steam pumps, each $4\frac{1}{2}$ inches by $3\frac{3}{4}$ inches by 4 inches for circulating drinking water.

1 Warren duplex vertical steam pump, $4\frac{1}{2}$ inches by $2\frac{3}{4}$ inches by 4 inches for circulating water through the ammonia condenser, the sanitary pump being connected for use as emergency.

1 Brine tank with direct expansion coils of 500 gallons capacity.

1 Scuttle butt for drinking water, with direct expansion coils of 400 gallons capacity. A water spray system over the ammonia parts is installed with a distant valve control for use in case of emergency.

The refrigerating plant takes care of the soda fountain and soft drink cabinets in both refreshment booths, an ice cream cabinet having a capacity for fourteen five-gallon reserve ice cream containers, the refrigerator for cold storage on the main deck forward and the refrigerator for steward's supplies adjoining the galley, in addition to drinking water which is obtainable from six fountains other than those at the refreshment booths and from faucets in the galley and engine room.

VENTILATION

Ventilation is provided for the mess room, kitchen and store rooms forward by three ventilators through the main deck with an exhaust ventilator from the galley carried into the stack casing. The crew's quarters aft receive their supply of fresh air through large cowl ventilators on the boat deck carried through trunks. The lavatories have exhaust ventilators led into the fan casing in the boiler room. A constant supply of fresh air to the various rooms contained in the main deck enclosures, port and starboard, is provided through shielded grills above the windows when these are closed. The canopy over the forward refreshment booth has an exhaust duct which is led into the stack casing. There are four 24-inch diameter cowl ventilators to the engine room and two of 30 inches diameter to the boiler room.

ELECTRIC EQUIPMENT

The main generating equipment consists of two 15 kilowatt General Electric generators connected in parallel, though one generator has sufficient capacity for the normal load. The main switchboard is located in the engine room and has mounted upon it the necessary switches to control the dynamos, search light, running lights, power circuits for the deck machinery along with feeders to auxiliary lighting circuit panels. All the main feeders are of armored cable while the lighting circuits are either of armored cable or carried in metal conduits to suit the local conditions.

The fixtures generally are of the ceiling type with enclosed Holoplane globes which, in the more exposed places, are of the watertight type. The complete electric and communicating equipment installation was carried out by Charles Cory and Son, Inc., New York.

PROPELLING MACHINERY

The main engine is of the four cylinder, triple expansion, direct acting surface condensing type with cylinders 24, $37\frac{3}{4}$, 44 and 44 inches diameter by 30 inches stroke, designed for a working pressure of 200 pounds per square inch and developing 2,900 horsepower at 155 revolutions per minute with independent condenser and pumps. The thrust bearing is of the Kingsbury type.

BOILERS

Each vessel is equipped with two Babcock and Wilcox marine watertube boilers each having 3,739 square feet of heating surface, or a total of 7,478 square feet, with furnaces arranged for oil fuel. The boilers are 23 sections

wide, each section having $7\frac{1}{2}$ clusters of four 2-inch tubes, with one 4-inch tube over the furnace, the tubes being 9 feet long.

Each boiler is equipped with five Babcock and Wilcox mechanical atomizing oil burners, Buyama design, arranged to operate under forced draft. The blower delivers the necessary air to the duct surrounding the oil burners, formed by the inner and outer front plates of the boiler, the outer front plate being so designed that the burners can be operated with natural draft, if necessary.

Coen three unit 12 by 50 steel construction cleanable oil heaters of the latest design have been installed. With these heaters the oil passes between an inner and outer element, and there are no coils, the absence of which is one of the noteworthy improvements in this heater, permitting of cleaning with the least amount of trouble and delay.

The fuel oil strainers for both the suction and discharge side are the Coen duplex type, with double baskets which have a combined area approximately eight times the cross sectional area of the pipe. A single 90-degree turn of the handle changes from one basket to the other basket allowing the strainer to be cleaned while the burners are in operation.

FORCED DRAFT SYSTEM

Each ship is equipped with one 78-inch double inlet Howden forced draft fan driven by one 7-inch by 5-inch Howden enclosed forced lubrication engine.

The fan units are situated in the boiler room just aft of the boilers and deliver the air into ducts passing below the boilers. The boiler fronts are so arranged that, by moving dampers, the furnaces will be supplied with air either under natural draft alone, with natural draft assisted by forced draft or entirely by forced draft.

Owing to the solid central plate construction of the Howden fan it has been possible to use one inlet of the fan to ventilate the lavatories, etc., in the upper part of the ship, the other inlet taking the warm air from the engine and boiler rooms. Running on forced draft, the fan units, which are somewhat larger than necessary, are capable of running the boilers at high rating, thus giving a reserve which can be called on in emergency.

AUXILIARIES

There are two 10-inch by 7-inch by 24-inch vertical single main feed pumps operating against a working pressure of 210 pounds per square inch in the boilers. The pump ends are of cast iron heavily brass lined and brass fitted and are of the valve pot type in which the entire valve service is readily removed for inspection or repairs. The steam valve gear is of the well known Warren "Eclipse" type in which the main slide valve is mechanically operated instead of entirely steam thrown.

The feed water is heated by a Reilly type G, number 16 marine feed water heater.

There is one 10-inch by 22-inch by 15-inch main air pump of the vertical twin single-acting type having cast iron pump cylinders, brass lined and brass fitted. The head and foot valve decks are of brass as well as the pump buckets. The pump valves are of the multi-disk phosphor bronze type. Ample size handhole plates are provided in the suction and discharge chambers and also in the plunger barrels to permit of easy access to all valves.

The circulating pump, supplied by the Pusey & Jones Company, has a 12-inch suction and 10-inch discharge and is direct connected to a 9-inch by 9-inch Engberg vertical engine.

There is one 6-inch by 6-inch by 6-inch Warren vertical duplex piston pattern bilge pump having cast iron pump cylinders fully brass fitted. The pump cylinders are designed for 150 pounds per square inch pressure.

There is one 10-inch by 7-inch by 12-inch vertical duplex

(Continued on page 569)

Great Lakes Freighter Frontenac

Latest Addition to the Fleet of Lake Freighters Has Many Features, Including a Special System of Ballast Tanks and Pumping Arrangements

ON May 26 the 12,000 deadweight ton freight steamer *Frontenac* was launched at the River Rouge (Michigan) yards of the Great Lakes Engineering Works. This vessel which is to be used as a freight steamer was subsequently delivered to the owners, the Cleveland-Cliffs Steamship Company, Cleveland, Ohio, on July 28.

Since freighters in Lake service run rather to standard types, the improvements in design, construction and equipment in the case of the *Frontenac* have been more or less in minor details—the greatest innovation being in the construction of the ballast tanks and the method of equipment for handling the water ballast. Details of the system are given in a later section of the article.

The principal dimensions of the vessel are as follows:

Length overall	605 feet
Length on keel	580 feet
Beam, molded	60 feet
Depth, molded	32 feet
Deadweight carrying capacity at 20-foot draft, about	12,000 long tons
Water ballast capacity	6,700 long tons
Gross tonnage	8,158
Net tonnage	6,531
Service speed about	12 knots

TYPE OF CONSTRUCTION

The hull is of arch girder construction with a forecastle deck and pilot house forward. The machinery spaces are

located aft and here also are the coal bunkers and ship supply tonnage.

The cargo hold is divided into four compartments. The cargo hatches numbering eighteen in all are 38 feet wide, 12 feet long fore and aft and are spaced 24 feet on centers. The hatch covers are of the steel telescopic type, fitted with Mulholland fasteners and operated by wire cables which are led along the deck with portable posts and fixed cleats to the steam deck engines amidships.

Water ballast is carried in both the side and bottom tanks, the side tanks being separate from the bottom tanks.

DETAILS OF PROPELLING MACHINERY

Steam for the propelling machinery and auxiliaries is supplied by three Scotch boilers 13 feet 6 inches diameter by 11 feet 3 inches long, constructed to pass the requirements of the United States Bureau of Steamboat Inspection and of the American Bureau of Shipping, for a working pressure of 180 pounds per square inch. Each boiler has two corrugated furnaces 50 inches inside diameter and each furnace a separate combustion chamber.

The boiler shell is rolled from a single plate and has two longitudinal joints with double butt straps of equal width. The circumferential end seams are double riveted. The front head is made from a single plate $1\frac{1}{8}$ inches thick eliminating all doublers and horizontal joints. The back head is made in the same manner. Each boiler has 294 3-inch outside diameter tubes 7 feet 8 inches long, about 30 percent of which are stay tubes.

Heated forced draft is supplied by a sirocco fan through vertical tube air heaters. The grate bars are 5 feet 6 inches in length while the bridge wall installed is of the Sturrock type.

The inner stack is 6 feet 6 inches diameter and the outside stack 12 feet in diameter. The latter extends 40 feet above the top of the deck house.

PLAN

Inboard Profile and Spar Deck

Total heating surface—3 boilers.....	6,261 square feet
Total grate surface—3 boilers.....	137.25 square feet
Ratio heating surface to grate surface.....	45.7 to 1
Air heater heating surface	2,364 square feet

MAIN ENGINE

The main engine is a vertical triple expansion, three crank engine having cylinders 24½, 40 and 65 inches in diameter with a stroke of 42 inches. At 82 revolutions per minute normal speed this engine develops 1,900 indicated horsepower. The low pressure cylinder is placed at the forward end of the engine, the intermediate at the after end and the high pressure in the center with its valve chest on the out-board side of the cylinder. The high pressure valve is actuated through a rocker arm. This engine is about 18 inches less in overall length than an engine of equal size having cylinders and valve chests in line. The high pressure and intermediate pressure valves are of piston type and the low pressure valve is a double ported slide valve.

The high pressure and intermediate pressure piston have deep removable followers and the low pressure piston is fitted with one ring having flat springs fitted behind it. This ring is clamped between the follower and piston body making what is practically an adjustable plug piston.

The crosshead is of cast steel with brass shoes. The upper ends of the connecting rods are of the gib and key type with bronze boxes while the lower end has cast steel boxes lined with Ackermite bearing metal.

There are four front columns and three guide columns of box type all made of cast iron. The crank shaft is of the built-up type with cast steel slabs and is supported by four babbitt lined journals. All valves are operated by Stevenson link motion, the high pressure being operated through a rocker arm. The thrust bearing is of the ordinary horse shoe type.

The propeller is of cast iron, of the sectional type with four blades, having a diameter of 15 feet 0 inches, a pitch of 13 feet 9 inches and a developed area of 83 square feet.

AUXILIARY EQUIPMENT

The feed equipment consists of one horizontal simplex 14 inches by 8 inches by 16 inches main feed pump, one horizontal duplex 6 inches by 4 inches by 6 inches pump for feeding boilers in port, three injectors, one multi-coil feed water heater and three Learmouth type purifiers. The purifiers are 42 inches diameter and approximately 8 feet high.

Both top and bottom heads are of flanged steel. The entrance to the purifier is gained through a 12 inches by 16 inches manhole in the top head. Cleaning hand holes are also placed along the sides. The feed pumps take their suction from a feed tank installed in the engine room. The water supply for this tank is obtained from the discharge of the air pump and is augmented by the drains from the feed water heater and miscellaneous traps.

The general service pump is a 12 inches by 6 inches by 12 inches horizontal duplex and may be used for fire, feed and ash gun service. The mates' pump is a horizontal duplex 6 inches by 4 inches by 6 inches pump and is used for deck washing service. The sanitary pump is a horizontal duplex 6 inches by 4 inches by 6 inches pump. The main air pump is a vertical simplex combined air pump and jet condenser, size 18 inches by 36 inches by 24 inches.

The lighting equipment consists of two 15 kilowatt and one 10 kilowatt engine driven generators.

BALLAST SYSTEM

There are eight bottom ballast tanks divided at the center-line and seven port and seven starboard side tanks. The bottom tanks are piped through separate pipes in the double bottom to a double type manifold in the engine room, so that the tanks may be filled, emptied or water transferred from one tank to another at will. There is a fore and aft header on each side of the ship with connections to each side tank. Eight-inch angle shut-off valves, operated from the deck are placed at each tank. The piping system is so arranged in the engine room that the side tanks may be pumped full at the same time that the bottom tanks are being filled from the sea by gravity. This arrangement materially cuts down the time required for ballasting. The ballast pumps consist of two 14-inch centrifugal pumps of 6,000 gallons per minute capacity, and two 10 inches by 14 inches by 12 inches horizontal duplex pumps.

ACCOMMODATIONS

The propelling machinery, and commodious quarters for engineers, the steward's department, oilers, firemen and deckhands' are located in the after end of the ship. At the forward end is a sitting room and two staterooms for the owners, the captain's office and stateroom, pilot house; quarters for the mates, etc. The finish in the owners' staterooms is white enamel and the sitting room, dining room and officers' quarters are finished in oak.

Intercoastal Cargoes Increasing

THE Bureau of Research, United States Shipping Board, issued recently figures showing the movements of cargoes between the east and the west coasts of the United States for the first six months of 1923. The total cargo so moved amounted to 5,644,837 tons. Three-fourths of this movement was from the west coast to the east coast, and five-sevenths of this eastbound movement was composed of tank ship cargoes of petroleum. Leaving out the bulk oil traffic,

1,430,790 tons moved to the west coast, and 1,059,534 tons were brought to the eastward.

Los Angeles leads all the individual ports in quantity handled in this trade, her total being 3,727,240 tons against New York's 2,652,600. Los Angeles also stands first among the Pacific ports, both in eastbound and in westbound traffic, considered separately. On the Atlantic New York is foremost in amount of intercoastal cargo tonnage entered, while Baltimore leads in quantity cleared.

The rank of the first ten ports of the United States in intercoastal movement only—coastwise and foreign traffic not considered—is as follows, for the half-year: Los Angeles, 3,727,240; New York, 2,652,600; San Francisco, 795,987; Philadelphia, 749,354; Baltimore, 742,894; New Orleans, 332,261; Seattle, 263,141; Portland, Ore., 238,548; Boston, 223,649; Tacoma, 173,314.

To the already phenomenal growth of the intercoastal cargo trade there will undoubtedly be added a healthy gain to this route as to means of travel for passengers between the east and west coasts.

Influence of the Bulbous Bow on Resistance

Results of Recent Investigations at Government Model Basin Showing Effect of Varying Bow Slope of Sectional Area Curves

By Rear-Admiral D. W. Taylor, U. S. N. (Retired)*

FOR nearly twenty years the battleships of the United States Navy have been designed with bulbous bows because in the early days of the Model Basin at Washington searching for improvement in form we concluded that the bulbous bow, uncouth as it appeared, served to reduce battleship resistance. The bulbous bow was not altogether the result of hit or miss methods. Somewhere in the literature of ship resistance I had seen reference (by Mr. William Froude, I believe) to a so-called swan model having full but narrow water lines close to the bow succeeded by an almost parallel section which was followed again by lines swelling out to a normal form. The theory seemed to be to have first a false bow as it were, corresponding to a small ship. This would create a small bow wave and in its hollow was located the second or true bow, making a second bow wave that would neutralize the first.

We were never able to make a swan model that drove more easily than the usual form but the bulbous bow rather grew out of this research. Its idea was to fine the water line as much as possible and put the displacement removed from the vicinity of the water line as far below water as possible.

So instead of a fine bow forward with a second full bow abaft it we had a fine bow at the water line as it were and a full bow near the keel.

BULBOUS BOW NOT PATENTED

No attempt was made to patent the form or keep it confidential. In "Speed and Power of Ships," published in 1910, the Standard Series lines, the basic lines for a large

*Former Chief Constructor, United States Navy.

number of models used to investigate variation of resistance with variation of size, proportions and longitudinal fullness, were shown with a moderate bulbous bow. Concerning the bulbous bow I said in "Speed and Power," pages 93 and 94:

"It may be pointed out that experiments show a ram bow of bulbous type to be favorable to speed, even apart from the fact that the ram bow usually involves a slight increase in effective length. This is simply because the ram bow, which is the extreme case of the U bow, is much fuller below water than at the water line. The excess pressures set up around the ram being well below the surface are more absorbed in pumping the water aft, where it is needed and less absorbed in raising the surface and producing waves than if the same displacement were brought close to the surface."

So far as I know only one merchant vessel has ever been built with a bulbous bow and I am not sure that the venturesome marine superintendent who took a chance on it concluded that he had gained a faster ship by its use.

RECENT TESTS AT GOVERNMENT MODEL BASIN

We never made a thorough investigation of this bulbous bow matter during my time at the Model Basin. While it was kept in mind as one of the jobs to be taken up when a slack time came, somehow the slack time seemed never to come. But Captain Eggert, now in charge of the Model Basin, has recently finished some extensive tests in the field where I made a small beginning years ago and the results seemed so interesting to the naval architect that I sought and obtained permission of Admiral Beuret—the Chief Constructor of the Navy—to write them up. They throw much light not only upon the bulbous bow question but also upon an allied question of importance—namely, the effect upon

resistance of varying the bow slope of curves of sectional area.

In what follows, this slope is expressed by a quantity *t* obtained as follows, for the normal form, where the ordinate of the sectional area curve is zero at the bow or fore perpendicular:

Draw the tangent at the bow to the curve of sectional areas. This will cut the vertical at the center of length, intercepting on it a certain ordinate. Then *t* is the ratio be-

tween this ordinate and the ordinate of the sectional area curve at the center of length.

HOW THE BULBOUS BOW IS EXPRESSED IN FIGURES

Now we need to express the bulbous bow in figures, so to speak. This is done as follows: The sectional area curve instead of coming to zero value at the fore perpendicular has an ordinate there, representing an area at the fore per-

pendicular and the extent of bulbousness, if it may be so called, is expressed by the ratio between this fore perpendicular area and the area of the midship section. We thus have the shape that would be found, if we designed a ship with a very long under water ram and then cut it square off at the fore perpendicular.

However, we do not test a model with a square nose in front. Having made it as described above, the ends of the water lines are rounded in circular form, the radius varying with each line so that the circular termination passes through the fore perpendicular and is tangent to the water line of the square nosed form. In the figures the bulb section at the fore perpendicular is shown before rounding the corners thus corresponding to the actual section a short distance—a very short distance indeed—abaft the fore perpendicular.

In what follows the symbol f is used to denote the bulb area at the fore perpendicular expressed as a fraction of the area of midship section.

When f has a value it is necessary in order to determine t correctly to deduct f from both the midship ordinate of the tangent at the bow and the midship ordinate of the curve of sectional areas and then proceed as before.

FEATURES OF BULBS TESTED

Now what were the features of the bulbs tested? They are best characterized by the sections at the fore perpendicular. These are made tangent to the vertical at the water line for small bulbs but meet it at an angle for large bulbs, then swell out continually nearly to the keel and have a wide flat at the keel level. Figs. 7 and 8 show these sections.

In other words the bulb in the experiments I am dealing with was roughly of triangular section with its base at the keel level and its apex at the load water line.

The two sets of models I am particularly concerned with were Model Tank Series 45 and 46, but for brevity we will call them here the *A* and *B* series, *A* consisting of 20 models and *B* of 23 models. Their dimensions are given in Table I for *A* models and Table II for the *B* models. As may be seen, the *A* models were of fine block coefficient 0.552 and small displacement length ratio 60. Expanded to a 400-

Fig. 10.—Series A. $\frac{R_r}{\Delta} = 7.0$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 0.783$

foot length they would have displaced 3,840 tons with beam 45.66 feet and a draft of 13.62 feet only. This shallow draft renders it harder for the bulbous bow to show its full virtue.

Models *B* of 0.6435 block and 150 displacement length ratio, if expanded to a 400 foot length, would displace 9,600 tons on a beam of 64.64 feet and a draft of 20.2 feet. The are of battleship type while the *A* models are more of the fast passenger vessel or battle cruiser type.

It will be observed in Tables I and II that the wetted surface varies with t and f . The variations are not great enough to amount to much but are shown graphically in Figs. 1 and 2 as contours of wetted surface coefficient on ordinates of f and abscissæ of t .

Space does not permit giving the lines of the 43 models but Figs. 3 to 6 give information as to their forms. Figs. 3 and 4, referring to the *A* and *B* models respectively, show the constant water lines and the constant after body curve of sectional area. In each series the changes of form were entirely forward of the midship section and below the fore body water line, being greatest near the keel. Figs. 5 and 6 show the fore body curves of sectional area of the 20 models of Series *A* and the 23 of Series *B*, grouped by f values. To avoid confusion and at the same time save space, each group of these curves is kept clear vertically of other groups by suitable shifting of scales.

VARIATION OF f AREAS

Owing to the fact that for each group there is a wide variation of t the variations in the fore parts of the sectional area curves are quite as radical as the variations of f areas. As regards these latter—the f areas—Figs. 7 and 8 show for each model of each series the constant midship section, the bulbous section at the fore perpendicular and a section halfway between the bow and the midship section. Tables I and II should be consulted in connection with Figs. 7 and 8. Scrutiny of Figs. 7 and 8 make it obvious that many of the tested were remarkable. The models themselves show to the eye the variation of t as well as of f and to the conventional eye many of them would appear truly ridiculous. It is on

Fig. 13.—Series A. $\frac{R_r}{\Delta} = 16.1$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 1.230$

Fig. 14.—Series A. $\frac{R_f}{\Delta} = 21.7$. Contours of $\frac{R_f}{\Delta}$ for $\frac{V}{\sqrt{L}} = 1.454$

A separate set of contours was laid down for each value of $\frac{V}{\sqrt{L}}$, the usual dimensions less coefficient expressing speed, V being speed in knots and L length in feet.

At low speeds the frictional resistance is by far the major factor in the total resistance and only at very high speeds is it surpassed by the residuary. So in order to avoid forgetting this fact there is recorded upon each contour diagram a frictional resistance corresponding to the speed. Since the frictional surface varies slightly with t and f and the frictional resistance by our standard formulæ varies with length of

vessel, it is necessary to base the figures of $\frac{R_t}{\Delta}$ upon an aver-

age wetted surface and a definite length. For the *A* models the wetted surface coefficient used (see Fig. 1) was 0.3325 and for the *B* models (Fig. 2) 0.3390. The standard assumed

length was 400 feet. The values of $\frac{V}{\sqrt{L}}$ to which the several

diagrams refer do not convey much idea of actual speeds except to experts. But multiplied by 20 or $\sqrt{400}$ they become actual speeds of a 400-foot vessel. The speed of a

vessel of this length is $0.5 \times 20 = 10$ knots when $\frac{V}{\sqrt{L}}$

$= 0.5$. It is $0.8 \times 20 = 16$ when $\frac{V}{\sqrt{L}} = 0.8$ and so on.

Consider now the diagrams. Figs. 9 to 20 show contour diagrams that have been selected as typical from a larger number, Figs. 9 to 14 refer to models *A* and 15 to 20 to models *B*.

SERIES A—FINE, FAIRLY FAST VESSELS

Consider first the Series *A* figures. Fig. 9, corresponding to 11.18 knots for a 400-foot vessel, shows $f = 0.05$, $t = 1.0$ as about the best combination. Consider first, however, the case of the normal type vessel without a bulb. For this case $f = 0$. It is interesting to note in Fig. 9 that when $f = 0$ the residuary resistance varies decidedly with t , the pounds per ton ranging from the minimum of 0.45, when $t = 1.25$, to 0.6, when $t = 0$, and 1.1, when $t = 3$.

As we give f increasing values there is a falling off in t for best results. The minimum residuary is about 0.4 when $f = 0.05$. This is a 10 percent reduction from the minimum without a bulb. However, since the frictional resistance at this speed is about 3.7 pounds per ton, the gain from the bulb is only about 1 percent—a real gain but a small one.

Passing now to Figs. 10 to 14 we see that the actual residuary resistance and its relative importance increase

steadily with speed. Until $\frac{V}{\sqrt{L}} = 1$ about, corresponding

to 20 knots for a 400-foot ship, the best t keeps in the vicinity of 1. The best f increases steadily until it is over 10 percent at 20 knots. The maximum gain possible from the bulbous bow remains somewhere near 10 percent of the residuary up

to $\frac{V}{\sqrt{L}} = 1$, but at this speed it is some 3 percent of the total instead of 1 percent as at 11 knots.

Above $\frac{V}{\sqrt{L}} = 1$, in Figs. 12, 13 and 14, there is rather

a rapid change in type of the figures. In the first place for $f = 0$ the best value of t , which has been increasing slowly over that for lower speeds, increases rapidly until in

Fig. 14, when $\frac{V}{\sqrt{L}} = 1.454$, it is over 3. The best value of

f increases to 13 or 14 percent and the possible percentage of gain, from a bulbous bow, increases to over 6 percent in Fig. 14, if we hold t to the values best for speeds below

$\frac{V}{\sqrt{L}} = 1$. On the other hand, if we are bold enough to

choose t large enough, there is no gain at all from the bulb.

It is seen from Fig. 14 that for 29 knots on a 400-foot ship we would want t greater than 3. The curve of sectional areas of Model 2158 in Fig. 5 has $t = 3$ and it evidently approaches the swan form. Furthermore the bow is really of the bulbous type only the bulb does not extend to the fore perpendicular. The matter is not of practical importance for we know too much about the broad features of form to adopt

the 0.60 longitudinal coefficient of Series *A* for $\frac{V}{\sqrt{L}}$ in the

vicinity of 1.5.

TOTAL RESISTANCE REDUCED FROM 1 TO 3 PERCENT

Summing up the Series *A* results we may say that for it a properly chosen bulbous bow will save us something like 10 percent of the residuary resistance and from 1 to 3 percent of

the total for speeds up to a $\frac{V}{\sqrt{L}}$ value of unity. At higher

speeds the relative saving is less and disappears at speeds as

high as $\frac{V}{\sqrt{L}} = 1.5$, if we select t to suit the speed.

As regards t , the best value remains close to 1 until we reach a $\frac{V}{\sqrt{L}}$ value in the vicinity of unity. It then increases

rather rapidly with $\frac{V}{\sqrt{L}}$ until it reaches 3 when $\frac{V}{\sqrt{L}} = 1.25$ and increases still more for higher speeds.

Series *A* has thrown light upon a matter that had puzzled me for years. The Standard Series whose results were published in "Speed and Power of Ships" had good lines and was seldom surpassed as regards resistance by the lines of models tested in the Model Basin prepared by various naval architects. Now and then we had models that beat it at

some speeds but at about $\frac{V}{\sqrt{L}} = 1$, the Standard Series

seemed unbeatable. I feared that we had fared into the Standard Series results at about that speed something that did not exist; but bearing in mind that the Standard Series had a bulbous bow—though not a very large bulb—it is now evident that it thereby had a handicap in its favor at the very speeds where it seemed unbeatable.

SERIES B—RATHER FULL, MODERATE SPEED VESSELS

Let us now consider Series *B*—Figs. 15 to 20. Here we are dealing with a fat full-bodied vessel and there is no

use pushing our results much beyond $\frac{V}{\sqrt{L}} = 0.9$.

One thing that strikes us at once is that at low and moderate speeds the best value of t is not about unity but about zero.

While this may seem strange at first sight it is quite in accordance with many model tests of moderate speed vessels. Of course it is well known that for high speed vessels we

Fig. 15.—Series B. $\frac{R_r}{\Delta} = 1.6$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 0.447$

Fig. 17.—Series B. $\frac{R_r}{\Delta} = 4.7$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 0.805$

Fig. 16.—Series B. $\frac{R_r}{\Delta} = 3.9$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 0.715$

Fig. 18.—Series B. $\frac{R_r}{\Delta} = 5.3$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 0.850$

need large longitudinal coefficients which are associated with full ends and for low speed vessels small longitudinal coefficients with their resulting fine ends are the best. It almost seems from the A and B models that when we attempt to differentiate further for moderate speed vessels we should adopt as our slogan—"The Fuller the Body, the Finer the Bow."

THE FULLER THE BODY, THE FINER THE BOW

It will be observed in fact that for Series B the contours indicate minimum residuary at some speeds for negative values of *t*. Of course where *f* has a value, negative values of

t are physically possible as in Model 2416, but I will not undertake to pursue *t* below zero.

The table below summarizes Figs. 15 to 20.

Figure Number	15	16	17	18	19	20
$V/\sqrt{L}$	.447	.715	.805	.850	.894	.939
Corresponding speed for 400-foot vessel	8.94	14.30	16.10	17.00	17.88	18.78
Best value of <i>t</i> where <i>f</i> = 0	0	0	0.35	0.75	1.10	1.50
Best value of <i>f</i>	.03	.04	.07	.10	.13	.17
Corresponding value of <i>t</i>	0	0	0	0	.5	.5
Percent residuary resistance that can be saved by bulb	..	13	13	16	25	33
Percent total resistance that can be saved by bulb	..	3	3	6	13	18

Fig. 19.—Series B. $\frac{R_r}{\Delta} = 5.7$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 0.894$

Without attempting to draw too many conclusions from two series of experiments, it would seem evident that there are conditions where the bulbous bow is desirable from the point of view of resistance. Even if we do not take a chance with the f value needed to make the maximum saving, there are speeds where a much smaller bulb will be distinctly worth while.

In practice, a flat bottomed bulb would give trouble by pounding in a rough sea but a flat bottomed bulb is not necessary.

I have heard no complaints of pounding of the bulbous bows actually fitted on our battleships. The ingenious naval

Fig. 20.—Series B. $\frac{R_r}{\Delta} = 6.3$. Contours of $\frac{R_r}{\Delta}$ for $\frac{V}{\sqrt{L}} = 0.939$

architect will have no difficulty in devising bulbous forms where little or no furnacing of the structural plating is necessary.

EFFECT OF BULBOUS BOW ON OTHER TYPES OF VESSELS

In conclusion I may point out that Series A and B deal with two important types, the fine fairly fast vessel and the rather full moderate speed vessel. There are two other broad types of interest, the very full low speed vessel and the full very fast vessel such as a destroyer.

As regards the former the effect of the bulbous bow has not been investigated at the Model Basin. Such vessels generally have in service such extreme variation of draft forward that for them the bulbous bow would be a dubious proposition to say nothing of the fact that their speeds are generally below those for which from experiments to date the bulbous bow is indicated.

A series has been recently tested of the long full ended slab sides destroyer type and the savings by the bulbous bow seem decidedly less than for Series A and B. The results are of little interest to the mercantile shipbuilder while the results of A and B are not only of general interest but liable to have a direct dollars and cents bearing upon some problems of mercantile shipbuilding.

MONTHLY SHIPBUILDING REPORT.—The Bureau of Navigation, Department of Commerce, reports 116 sailing, steam, gas and unrigged vessels of 9,760 gross tons built in the United States and officially numbered during the month of July.

Powerful Sperry Searchlight Mounted on Foremast of the Leviathan

This 36-inch searchlight is the most powerful aboard any merchant vessel, and gives a 450,000,000 candle power beam. Reports from the trial trip of the "Leviathan" advise that an object was seen twenty-one miles by this searchlight, which, incidentally, is the same powerful type searchlight that was seen by the U. S. Army Aviators Kelly and Macready fifty miles from Bellville.

Details of Isherwood Design for Welded Ship—Process of Erection—The Caldwell All-Electrically Welded Barge

THE success obtained by the electric arc welding process urged men of initiative on to greater accomplishments, and Mr. A. J. Mason, while associated with the United States Shipping Board during the war period, proposed using a large electric spot welder in place of riveting for holding various members together, finishing the joints with electric arc welding in place of calking. This suggestion was approved by the United States Shipping Board to the extent that a 42 foot sample section of a 9,600 ton ship was ordered constructed. However, the signing of the Armistice caused

this work to be suspended, which is much to be regretted. "Had this experiment been carried to conclusion, it would have demonstrated a great saving in hull construction," Captain J. Caldwell, managing director of the Alloy Welding Processes, Ltd., remarked, in his report to the Emergency Fleet Corporation.

Fig. 68.—Midship Section, Isherwood Design for Welded Ship

and all parts ready for final welding. I wish to draw attention to the very small amount of welding to be done on the ship after erection.

Full welds of double bottom for: Butt seams, butt straps and butts of longitudinals, connection of center keelson plate top and bottom.

Light welds of double bottom for: One edge of outside seam strap, top and bottom of floor plates and transverse clips.

If the service bolt holes in the seams and butts are fitted with plugs and welded and the small connections at the intersection of the longitudinals with the floor plates are

Fig. 69.—Upper Deck Transverse Beam, Isherwood Design for Welded Ship

welded, then all riveting in the double bottom of the ship is obviated. It is assumed that the service bolt holes for the work done in the shop and on ground were filled up before material was brought to the ship and before erection.

Full welds of side plating and internal work: outside edges of shell overlaps, butts of shell plates and longitudinals, connection of transverse plates to shell clips and inner bottom plating.

Light welds of side plating only for inside edges of shell overlaps.

Full welds are used for seams of deck plating, butts of deck plating and longitudinals, heel of gunwale bar and connections of beams to transverse framing.

Light welds for connection of transverse beam plates to slips already on deck and for pillar and detail work.

Mr. H. Jasper Cox, in his paper read before the Society of Naval Architects and Marine Engineers, comments on the Isherwood design of welded ship, as follows:

"The system of construction lends itself to a large proportion of the total welding being done prior to erection, and in working out the details, no attempt has been made towards an unreasonable amount of elimination of bolting or riveting. For instance, the longitudinals are attached to

Fig. 70.—Transverse Floor at Shell and Tank Top, Isherwood Design for Welded Ship

the shell plating by service bolts spaced 12 inches apart and are welded at the toe and heel by continuous light welds; then the bolts are removed and rivets or welded studs fitted. In other parts, where the minimum number of bolts necessary to properly tighten up the work approaches the total number of rivets required in a riveted ship, the designer has simply added the extra rivets instead of attempting to weld."

Further details of construction can be found by studying the accompanying plans kindly furnished me by Sir J. W. Isherwood.

THE CALDWELL ALL ELECTRICALLY WELDED BARGE

Major James Caldwell, managing director of the Alloy Welding Processes, Ltd., London, has prepared a design for an all electric arc welded barge using the conventional transverse frame ship design with certain modifications in details of construction. This design is based on the experience gained from the building at Richborough Dockyard of the barge previously described and known as the AC-1320.

The principal dimensions of Major Caldwell's barge are

Fig. 71.—Section Through Side Stringer, Isherwood Design for Welded Ship

length between perpendiculars 125 feet 3 inches, molded breadth 16 feet 5 inches, molded depth 8 feet 6 inches. Displacement at 5 feet 3 inches draft is 280 tons and on 6 feet 0 inch draft 320 tons. The propelling machinery is an 80 horsepower, 2 cylinder, 4 stroke oil engine, weighing 5 tons. Total weight of the barge is estimated at 80 tons.

Major Caldwell states that the principles governing the substitution of arc welding for riveting in the construction of a ship are as follows:

1. Obtaining equivalent strength.
2. Minimum of overhead welding.
3. Ease of repair.

In commenting on these three basic principles of design,

Fig. 72.—Attachment of Cantilevers to Hatch Side Coamings, Isherwood Design for Welded Ship

he states: "Tensile and alternating stress tests repeatedly carried out during the last twelve months on ship plates welded with covered electrodes have shown that compared to equivalent riveted joints, the arc welded joint is consistently superior in ultimate strength, and is, moreover, water and air tight up to its breaking point, whereas a riveted and calked joint fails in watertightness at 10 percent of its breaking load. It is sufficient for the purpose of this report to state that in plates up to $\frac{3}{8}$ inch thickness a continuously welded lap joint is about 100 percent stronger in tensile strength

Fig. 73.—Details of Construction, Isherwood Design for Welded Ship

Fig. 74.—Profile and Deck Plan, Caldwell Arc Welded Barge

than a standard riveted lap joint and it is estimated that in no part of the design are the welded joints less than 50 per cent stronger than the equivalent riveted joint.

OVERHEAD WELDING

Welding in an overhead position increases labor cost owing to the slower speed obtainable and the tiring of the operators. Reliable welds can be made in this position where the necessary headroom is available, but in cramped positions it is difficult. For economical reasons it should be avoided where possible. Careful attention has been given to this point in this design and overhead welding is avoided to a considerable extent by suitable arrangements of the joints

with engineers of extensive experience in ship repair the relative merits of welding and riveting for the general attachment of plating to frames and floors. As a result, it has been decided that the advantage of welding considerably outweighs the risk I have mentioned which should not occur unless unskilled labor is utilized. As a further precaution, I suggest the introduction of "attachment" strips between frames and plating, which would bear the whole force of possible damage when plates were cut away and replaced by new plating welded to the hull. However, as a result of experience, should it be found preferable for this work to be riveted this method could be adopted without alteration of design.

The superiority of continuous welded joints over equivalent riveted joints in both tensile and shear stresses is so marked that considerable economy in the amount of welding has been obtained by substituting "tack" welding (spaced welds of short lengths) for continuous welding wherever possible without sacrificing the factor of safety in any way. On shell, bottom and deck plating, and watertight bulkheads, continuous welding is adopted to ensure watertightness. For the shell seams the plates are joggled with continuous welds on both edges. For the vertical joints, butt straps are used of light section with continuous butt weld between plates and tack welded between straps and plates.

In general, all watertight work is continuously welded, and non-watertight work tack welded.

In connection with erection the assembly of fabricated sections of the barge on the ground for subsequent erection on the ship has such manifest advantages in enabling the welding to be carried out in the easiest position thereby reducing overhead welding and facilitating inspection that it should be adopted to the greatest possible extent.

Welded construction adapts itself well to such fabrication as well as the use of jigs and templates for rapid production of repetition work such as frames, floors, bulkheads, etc.

SCHEME OF FABRICATION

The following scheme of fabrication is estimated to facilitate welding operations and decrease labor cost.

Frames, floors, frame beam and bracket knee and center keelson lugs to be tack welded in the field and erected in one piece.

Deck plating in way of hatches to have half beams, gunwale bar, deck coaming bar and alternate butt straps welded in the field and erected in sections.

Hatch coaming plates to be erected with stiffeners, beam lugs, hatch cleats, molding and hatch cover rest bars all welded.

Side shells to have seams with a continuous fillet weld out-

Fig. 75.—Midship Section, Caldwell Arc Welded Barge

and the adoption of a carefully planned system of fabrication of sections before erection. When overhead welding is unavoidable, plenty of headroom is available and the weld is in an easily accessible position.

Before adopting an all welded design of construction careful consideration was given to the question of probable repairs arising from the usual risk of collision and going ashore.

No difficulty is foreseen in cutting out damaged and holed plating with welded laps either by pneumatic tools, oxy-acetylene blow pipe or cutting arc, and the replacement of such plates by welding would be a very simple and satisfactory job. The removal of plates welded to frames and floors is not such a simple matter and there is risk of damage to such frames and floors during the operation of cutting out. I have, therefore, very carefully considered and discussed

side and continuous light weld inside but moldings and alternate butt straps should be welded onto the plates before erection.

Bottom shell laps to have continuous strength weld inside and light weld on outside.

All shell plates butt welded on ship with inside strap tack welded on outside.

The calculated total welding on this vessel is equal to 9,000 feet of continuous welding on 5/16 inch plating. Of this amount 4,000 feet can be performed in the field under the best conditions leaving 5,000 feet to be carried out in position on the ship after erection.

The regulations governing welded ship construction as laid down by Lloyd's Register of Shipping provide for efficient supervision of welders, and maximum and minimum current densities in the electrode.

Minimum throat thickness of fillet welds, etc., are also insisted upon and are easily checked.

THE PARAFFIN TEST

Further it is proposed to use the paraffin injection test on watertight joints. This test which consists of projecting paraffin against the line of welding with a syringe has already proved an exceedingly useful and efficient method of detecting porous and unsound welds in the construction of welded tanks, etc.

This barge design was worked out by Mr. G. Rowell, naval architect, employed at the Richborough Dockyard during the building of the Barge AC-1320.

Accompanying copies of plans of Major Caldwell's barge will furnish further detail information.

(To be continued)

Mechanical Oil Burner Designed with Self-Contained Forced Draft

THE latest type of mechanical atomizing oil burner, the Mayflower design, developed by the Babcock and Wilcox Company, New York, incorporates a self-contained forced draft system.

The burner consists of the main casting with a bladed cone, to which a hollow shaft turbo blower is attached. The atomizer fits through the blower shaft and may be moved in and out by the adjustment of coupling studs. A quick detachable

yoke and coupling, similar to that used on other Babcock and Wilcox types of burners is also fitted to the atomizer. An impeller blade is fastened to the bladed cone by means of lugs. Access may be gained to the furnace by swinging aside the burner which is hinged. This also provides for the insertion of a fire tile plug which is put in place when the burner is not in use. Steam connections to the turbine are detachable and somewhat similar to the quick detachable yoke and coupling used on the oil burner connection.

The special advantages claimed for the burner are that on forced draft work it eliminates all ducts as well as the large blowers supplying air to the ducts; further, any number of burners can be run independently without having air leakage through dead burners, as is sometimes found when double front construction is used. As the air for combustion can be regulated very closely to the required amount, owing to the multiplicity of speeds available with the turbo blower, higher efficiency can be obtained.

When installing these burners, the steam piping can be so arranged that one master valve on the steam supply to the turbines regulates the air supply to all burners in operation with but a single adjustment. The oil supply to all burners can also be regulated by a master valve located adjacent to the steam master valve. By this method, one man can control any number of units obtaining the correct combustion with the minimum amount of work.

This type of burner has been thoroughly tested by the United States Navy at the fuel oil testing plant of the Philadelphia Navy Yard and found satisfactory.

S. S. CLEVELAND TO BE CABIN SHIP.—The steamship *Cleveland*, recently acquired by the United American Lines, is at the Blohm and Voss shipyard at Hamburg, Germany, where she is being reconditioned and converted to an oil burner prior to entering regular service as a cabin ship. Her first and second class accommodations are being combined into a single cabin class. When the work is completed the vessel will accommodate approximately 500 cabin class passengers and 700 third class passengers in rooms. Captain E. C. Tobey, vice-president in charge of operations for the United American Lines, is in personal charge of the reconditioning of the ship. The *Cleveland* will take up regular sailings between New York, Cherbourg, Southampton and Hamburg this fall.

Turbine Electric and Geared Turbine Drive

All Factors Affecting a Particular Ship Should Be Considered Before Selecting Type of Propelling Machinery

By W. C. Watson and John Thomas*

AFTER reading Mr. Shaw's article headed "An Analysis of the Claims of the Electric Drive over the Geared Drive," which appeared in the July issue of *MARINE ENGINEERING AND SHIPPING AGE*, a few readers of this magazine no doubt have gained the impression that the General Electric Company is advocating turbine electric drive for all types and sizes of steamships. It appears that Mr. Shaw has misunderstood the purpose of our article headed "How to Get a Shaft Horsepower Hour for All Purposes with Steam on from 0.75 to 1.00 Pound of Oil," which appeared in the May issue of *MARINE ENGINEERING AND SHIPPING AGE*, and was written to inform the marine fraternity of the possibilities to be obtained through the use of turbine electric form of propulsion.

Mr. Shaw has made the statement that the article was conspicuous due to absence of detail data to substantiate the claims made for this form of propulsion. However, the data have been thoroughly discussed and approved by reliable shipbuilders and ship operators in this country and abroad, and we would be pleased to forward copies of the detail calculations to any interested parties, as they were purposely left out of the article on account of the mass of detail involved.

MANUFACTURES THREE TYPES OF SHIP MACHINERY

The General Electric Company is engaged in the study and manufacture of Diesel electric, turbine electric and geared turbine propulsion machinery for ships, and is attempting to determine the proper installation for each particular ship.

DIESEL ELECTRIC DRIVE

A number of vessels have been equipped with Diesel electric propulsion apparatus, trial results of which indicate that the future for this type of drive is very promising. Further discussions will appear in later publications.

GEARED TURBINE DRIVE

The General Electric Company has been engaged in the design and manufacture of marine geared turbines for eight years, and has built over 2,000,000 horsepower of which approximately 1,300,000 horsepower has been installed in destroyers and is of the single reduction type corresponding to 1,000,000 horsepower manufactured by the William Cramp and Sons Ship and Engine Building Company as referred to by Mr. Shaw. While these reduction gears furnished by both companies have given no trouble, all marine engineers appreciate that equipments of this type are only suitable for vessels where full power is seldom employed, and are not suitable for cargo and passenger ships when efficient propeller speeds are employed. In addition to these single reduction gear equipments, the General Electric Company has equipped 322 merchant ships involving approximately 800,000 horsepower of the double reduction type. While 12 of these vessels were sunk during the war and 34 have had machinery replacements, the average mileage steamed by the remaining 288 vessels is approximately 93,000 miles each, and today about 200 of the geared turbine vessels in actual operation under the American flag are equipped with General Electric Company double reduction geared turbine machinery. Ninety-eight of these vessels have steamed an average of 120,000 miles each without gear replacements.

Although thoroughly reliable double reduction geared turbine equipment can now be obtained for cargo vessels requiring from 2,000 horsepower to 4,000 horsepower per propeller shaft, no marine engineer should attempt to specify one type of propelling machinery for all steamships. Turning to larger passenger and cargo vessels, our experience and knowledge of the problems encountered lead us to believe that a greater degree of success can be encountered with the turbine electric drive than with any other form of propulsion. There are certain cases in the smaller powered steamships where flexibility of control and other considerations influence the marine engineer in favor of turbine electric drive.

TURBINE ELECTRIC DRIVE

The problem of comparing the results of two vessels equipped with different types of propelling machinery is extremely difficult, even when the vessels are of the same type. Mr. Shaw has presented certain curves to prove superiority of geared turbines over turbine electric propulsion, and in so doing has compared a 32,000-ton displacement, 28,000-shaft horsepower, 21-knot battleship with a 7,600-ton displacement, 90,000-shaft horsepower, 35-knot light cruiser. It would appear to us that it would be just as practical to compare the performance of the 1,800-horsepower 71-knot motorboat *Miss America 2nd* with the 4,200-intermediate horsepower 11½-knot motorship *William Penn*.

In either case the boats are of entirely different types and designed for entirely different service, and the machinery for one would be unsuitable for the other without extensive alterations, which would materially change the results. Furthermore, the electric drive battleships have four screws instead of two, as mentioned by Mr. Shaw. We believe that a comparison of electric drive battleships with the only geared turbine battleship in the U. S. Navy, the *North Dakota*, would have been more valuable to readers of *MARINE ENGINEERING AND SHIPPING AGE*, but while the electric driven vessels show a marked improvement in fuel consumption over this battleship, we will not include a comparison as the *North Dakota* has certain machinery details which might make a comparison misleading.

EFFICIENCY AT CRUISING SPEEDS

Mr. Shaw has made the claim that the geared turbine machinery is far superior to turbine electric drive at cruising speeds, and while marine engineers appreciate that geared turbine installations can be designed for as efficient operation as electric drive at a definite speed, all fair comparisons have shown that the turbine electric drive is superior at reduced power when more than one turbine generating set is employed. This has again been confirmed by recent studies of electric drive for naval vessels for various navies of the world. At several different speeds it is possible with the electric drive to shut down all but one main generating unit and turn all propellers with this one unit and to maintain at least half speed of the vessel. Pole changing propulsion motors are usually installed in such ships, which enable the operator to run the one main generating unit at efficient speeds during cruising operation of the ship. On the other hand, with the geared turbine installation it is necessary to operate practically all of the engine room machinery at cruising speeds, which also makes it difficult to make repairs to most of the machinery while the ship is under way.

* Marine department, General Electric Company, Schenectady, N. Y.

FUEL CONSUMPTION

There has been considerable discussion concerning the fuel consumption of the five turbine electric driven vessels of the *Eclipse* type, and Mr. Shaw included a few figures on their operation. During the war there came a time when the mechanical drive facilities of the country were fully employed. Since the building of engines was the limiting feature of the shipbuilding program, the Emergency Fleet Corporation turned to turbine electric drive as a way of increasing the output of propulsion machinery. The five electric ships of the *Eclipse* type were the only cargo boats equipped with the turbine electric drive as a result of that program. The propulsion turbines, generators and motors installed in these vessels were accurately tested at the factory at the time of manufacture, where the most refined measuring apparatus was employed and there is no doubt as to actual steam consumption of these units. No material improvement in fuel consumption over that of good geared turbine installations could be expected, and the ships have been studied by the advocates of electric drive primarily from the viewpoints of reliability and low cost of upkeep. The same boilers, which were not the most suitable for superheaters, and the original auxiliaries were maintained at the time the geared turbines were removed to permit installation of electric drive.

FIRST ELECTRIC DRIVE CARGO BOATS

It should be recognized that these were the first electric drive cargo boats in this country, and while they are not well balanced installations and do not represent what can be done today, the average fuel consumption of the *Archer* is approximately 1.16 pounds of oil per shaft horsepower hour for all purposes, as mentioned by Mr. Shaw, which is as good as the average geared installation and all that one could expect on this particular ship. The performance of these five cargo boats, as well as the performance of naval vessels and the four Coast Guard cutters of the *Tampa* type, has demonstrated without question the reliability of the turbine electric propulsion machinery, and has also established the fact that the maintenance expense is less than for any other form of ship drive. The turbine electric drive has proven itself extremely popular with the crews, and chief engineers have made the statement that they consider it easier to go to sea with a green crew on an electric ship than with any other form of propulsion.

The possibility of short circuits in the electrical machinery is very remote, and if they do occur, are not liable to disable the vessel. All live parts are well protected and contact with them is very difficult unless purposely done. The selection of the induction or synchronous type of propulsion motor depends entirely upon the application, and Mr. Shaw's statements concerning these types of motors are somewhat misleading. No attempt has been made by electrical experts to establish the synchronous motor as the most suitable for all propulsion applications.

No serious concern has been exercised over the smaller air gap of the induction motor, as experience over a period of ten years has shown that the induction motor is entirely suitable for such work. Both induction and synchronous motors have advantages for marine propulsion. The synchronous motor now offered by the General Electric Company primarily for the propulsion of single speed vessels might better be called a synchronous induction motor, as it combines the essential characteristics of each type. It is maneuvered as an induction motor and is operated as a synchronous motor at unity power factor only for steady running ahead or astern. Furthermore, this motor can be operated continuously at approximately half speed as a squirrel cage induction motor.

EITHER TYPE OF MOTOR EFFICIENT

Based on the performance of six ships equipped with the synchronous motor drive and a number provided with induc-

tion motors, there is no pronounced tendency for either type of motor to fall out of step under any conditions encountered at sea. The accessibility of parts for any repairs that have to be made is the principal advantage of the synchronous over the induction motor, but there is also some saving in weight and a slight advantage as regards efficiency.

In conclusion we wish again to point out that no type of drive can be recommended for a particular ship until all factors have been considered, and no single type of drive can be recommended for all seagoing vessels.

Steamer Wrongfully Libeled

THE plaintiff libeled the *Consuelo*, a Spanish steamship of steel construction, and caused an attachment to be issued against the ship, as a result of which she was arrested and taken into possession by the marshal and held, but was later voluntarily released when the plaintiff learned that their claim was against a French vessel of wood construction which bore the same name. The Court in *Artinano vs. W. R. Grace & Company*, American Maritime Cases Vol. 1, page 546, said that in an action at law, one who in error libels in a foreign port a vessel which bears the same name as another vessel against which he has a claim, but which is otherwise in every outward characteristic totally different and readily distinguishable from the vessel which he is pursuing, shows such gross negligence, similar to malice, as to become liable for actual damages flowing from the detention.

THE BOARD OF CITY COMMISSIONERS, Bayonne, N. J., has received a proposal which contemplates a huge marine and industrial terminal at that city, to cost \$150,000,000, with warehouses, piers and railroad terminals.

Depression Leads British to Urge Government Aid

Scheme to Assist Shipowners to Replace Obsolete Vessels Proposed—Loans on New Ships and Bounties Suggested

By a Special English Correspondent

IF certain factors may be taken as reliable indications—and, so far as I can see, there is no reason why they should not—the shipping industry of the United Kingdom, and with it, presumably, that of other leading maritime nations, is in for what is universally known as “a lean time.” The root of the trouble seems to lie in the international, political, economic and financial conditions which continue to obtain, and unhappily there is, at this writing, little sign of improvement. The quarterly figures which the Chamber of Shipping have now issued, covering the laid-up tonnage in the principal ports of the United Kingdom, show how the grip of the depression tightened during the second quarter of the year, the laid-up tonnage on July 1, having increased by as much as 30 percent as compared with April 1. The Chamber’s figures relate to British and foreign shipping, and the extent of the fluctuations over a period exceeding twelve months will be seen at a glance from the following:

TONNAGE LAID UP AT THE PRINCIPAL PORTS OF THE
UNITED KINGDOM

POOR REPORTS FROM OLD-ESTABLISHED SHIPPING COMPANIES

There is another indication of the disquieting situation in which the shipping trade finds itself, and that is in regard to the annual reports and balance-sheets of the principal companies, which documents have lately been published in rather a bunch. Frankly, the results shown in some of these accounts are undeniably poor. Take, as an example, the old-established Anchor Line (Henderson Brothers), Ltd., whose profits during the past year amounted to only £23,238, being a reduction of no less than £127,000 as compared with the previous year and of £172,000 as compared with two years ago. The result is, indeed, the poorest since 1908-9, when the company sustained a loss of £16,000. The directors of the line make no secret of the fact that the conditions which ruled in the shipping industry during the currency of the report have been the worst for many years past.

Another well-known shipping concern whose earnings are a good deal below the level of previous years is Furness, Withy and Company, Ltd., the profits during the past financial year amounting to only £552,510, as compared with £655,206 a year ago, and slightly more than a million sterling in the year ending April, 1920. The directors, pursuing their policy of conservatism, have set aside £200,000 for depreciation the same as a year ago, and have reduced the dividend and bonus distribution from 10 percent to 7½ percent. Fortunately the company is in an excellent financial position, and it is by no means dependent on shipping for its livelihood, for its interests extend to insurance and many

other branches. Indeed, were it not for some of these subsidiary operations the company might have been hard put to make anything like a good showing this year, because a substantial proportion of the earnings were contributed by these “outside” bodies.

ACCOUNTS OF LARGEST CARGO CARRYING COMPANY

Touching on shipping accounts, the figures of the St. Just Steamship Company, Ltd., Cardiff, managed by Sir William Reardon Smith and Sons, Ltd., make particularly interesting reading, for the concern owns the largest cargo carrying fleet of any company in the United Kingdom, with the possible exception of one or two companies whose interests are linked up with leading liner companies. Unfortunately the accounts of the St. Just Company are presented in such a way that it is impossible to ascertain what the profits amounted to in the nine months covered. No alarm need be felt on this score, however, for it is the exception to the rule for British shipping companies to convey in their accounts anything like a real impression of the financial results of the services conducted. The history of this company, as vouched for by the managers, is certainly an interesting one, and serves the useful purpose of illustrating the fluctuations assailing shipping enterprises. The company was formed at the end of 1912 and commenced trading in April, 1913. The original capital of the company was £90,000, which was increased from time to time up to March, 1919, by several increases of capital and by amalgamation. The total cash subscribed by shareholders was £645,000, the balance of the present capital of £2,064,000 being by way of bonus shares. In addition, however, to the bonus shares, the shareholders have received dividends calculated on their actual cash investment at an average rate of over 15 percent per annum, free of tax.

LOOKS LIKE A SUBSIDY

So much for the past. Reverting to the current year, the directors have reduced by £500,000 the cost of the steamships and investments, less reserve for depreciation. That sounds like a fine achievement, but obviously this half-a-million sterling was not written off from earnings of £91,604. The sum is believed, however, to have been obtained from the Government in connection with the agreement that it should pay part of the increased cost of steamers ordered during the war, such increase having been contributed to or caused by the action of the Government in delaying completion while standard boats were building. The directors have decided to pay a dividend of only 1¼ percent, but, owing to various bonuses in the past, referred to above, this distribution represents a much greater percentage on the original capital of the company.

GOVERNMENT AID BY LOANS ASKED

With the continuance of depressing times it is only meet that captains of industry and others should look into the possible or probable remedies for shipping and other ailments. This line of action is now being taken in the United Kingdom. Mr. F. E. Powell, the chairman of the Anglo-American Oil Company, Ltd., and the President of the American Chamber of Commerce in London, is responsible for the suggestion that the Government should assist in arranging loans

at a low rate of interest to shipowners on new ships built within the next three years, to be repaid over a period beginning two years after the vessels are in commission. Mr. Powell's plan is to scrap the existing obsolete tonnage, and, in its stead, build new, up-to-date vessels.

BREAKING UP BOUNTY ASKED

In addition, to induce shipowners and others to scrap old or obsolete vessels, Mr. Powell thinks that the Government should make a proposal that on all old ships sold to be broken up, and where the owner places orders for an equivalent new tonnage, with British builders, the Government should pay a bounty of, say thirty shillings per ton deadweight of the vessel broken up during 1923, and half that amount on boats broken up during the next two years. The value of old ships as scrap being about thirty shillings per ton deadweight, Mr. Powell reckons that owners would get about £3 per ton for the old vessel. He considers that the result of this would be that every shipyard in England would be full of work, and that, as "there is hardly a port in England where the facilities are what they ought to be," the docks of the country could also be assisted to improve and enlarge. To sum up, Mr. Powell maintains that the Government should arrange loans at not more than 3 percent interest for approved work begun in 1923 and 3½ percent for work commenced in 1924. "After that, the position is to be reconsidered as regards further new work," Mr. Powell concludes.

Having outlined, in necessary detail, Mr. Powell's scheme, let us see where his suggestion, if carried through to its logical conclusion, would be likely to lead us. On the surface, the construction of such a large amount of tonnage as would be involved would be a good thing for shipbuilders and their employees, but it is useless to disguise the fact that, if such a situation were created, the shipbuilding and engineering workers would inevitably demand higher wages such as would cripple the whole deal. But, apart from this aspect, it is feared in quarters competent to judge that, while the suggestion might prove a satisfactory temporary palliative, it would probably be of no more permanent benefit than the "doles" now being paid to the unemployed. It is felt that the scrapping of obsolete and inefficient tonnage will take place as a matter of course in the near future, inasmuch as the cost of laying up will force the hands of owners directly the freight market outlook makes it clear that remunerative employment for the boats is not, and will not be, forthcoming. As to the suggestion that the Government should arrange loans for shipowners at 3 percent per annum, it is thought that if shipowners availed themselves of such an opportunity it would be suicidal for them, and with them others, to spend money on producing boats for which no employment could be found.

REGULATION OF SERVICES

A suggestion from another quarter which has received attention here revolves round what are termed the "off" seasons—notably the middle months of the year. In those seasons many more passenger and cargo liners run than the trade which is offering warrants, there being, of course, no agreement in existence to restrain companies from continuing to employ their surplus vessels at heavy losses. It is suggested, therefore, that, during these "off" seasons, the companies might restrict their services, with due regard to the convenience of passengers, shippers and mails.

As matters stand, each shipowner or shipping company would seem to fear that any individual attempt to adjust the freight situation on the lines laid down would have the inevitable result of diverting traffic to competitors. It is realized that the scheme, to be successful, would have to be dealt with internationally, but it is maintained that it ought not to be beyond the capabilities of leading shipping men to devise an arrangement satisfactory to all of the parties.

Arguments for and against the motorship continue to exercise the minds of British shipowners, but, whatever doubts some may have as to the future for this type of craft, Messrs. Furness, Withy and Company seem pretty well satisfied with their experiences, so far as they have gone. They have for some time been carefully investigating the possibilities of the internal combustion engines, and, to use the words of their chairman, Sir Frederick Lewis, while there is no doubt a certain amount of development work still to be done before this type of marine engine is perfected, and the extra cost of production militates against any extensive program until these costs are reduced, still, as a result of their experience, Messrs. Furness, Withy have felt justified in contracting for two new vessels to be fitted with internal combustion engines.

BATTLE OF THE PORTS

The "Battle of the Ports," with London, Liverpool and Southampton as the eternal triangle, goes on. One has grown accustomed to learn, at various periods, that first one, and then another, of these ports is destined to become the "Supreme Port of the World." Liverpool and Southampton having taken their turn, and, incidentally, to some purpose, it is now considered as only right and proper that the searchlight of publicity should be centred on London. The Port of London Authority, who, as its name implies, is the controlling body, proposes new port works which are estimated to cost five millions sterling, the new facilities including dock improvements and the erection of a landing stage at Tilbury. It has been decided to construct a new dock, with a passage 80 feet wide, within the triangle now occupied by the Canada, Center and Quebec Ponds, which will afford five additional ship berths, each 400 feet in length. At Tilbury, which is actually 26 miles from London, but nevertheless a part of the London dock system, the authority has decided that the time has come for an entirely new dock to be constructed, of a size, both as regards the entrance lock and dry dock, and with a water area, adequate to meet the requirements of any ship built, building or likely be built for many years to come. The new entrance lock will be 1,150 feet in length, and will have a breadth of 130 feet. A dry dock of similar dimensions is also to be provided, but at the outset the length will, temporarily, be restricted to 800 feet.

Perhaps chief interest, however, attaches to the new landing stage at Tilbury. Lord Devonport, chairman of the Port of London Authority, has pointed out that some people hold the view that London is not, and never will be, a great passenger port. That is not Lord Devonport's view. He considers that, given adequate and comfortable facilities, the passenger traffic will expand, and he anticipates with confidence a great development. Tilbury Dock is estimated by the Authority's chief engineer to be finished in five years, and the bulk of the remainder of the program in about two and a half years. It only remains to add that the Government is putting up four and a half millions of the money, which is repayable, at interest of 3½ percent per annum, over a period of 30 years.

STANDARD OIL TUG BOAT LAUNCHED.—The *Socony No. 9*, the second of two steel single screw tug boats building at the Tebo plant of the Todd Shipyards Corporation for the Standard Transportation Company of New York, was launched on August 6. These tugs are to be equipped with vertical compound surface condensing engines with cylinders 18½ and 40 inches diameter by 26 inches stroke designed for a speed of 125 revolutions per minute. Steam will be furnished at a working pressure of 160 pounds per square inch by Scotch marine boilers with a heating surface of 2,700 square feet and equipped with Todd fuel oil burning equipment. The tug boats are 105 feet 9 inches long overall, 24 feet molded beam and 12 feet 9 inches molded depth.

Two Recent Single Reduction Turbine Installations

Cruisers *Gustav V* and *Drottning Victoria* of Swedish Navy Obtain Excellent Trial and Performance Results

By J. D. Schmidt*

THE excellent results obtained on trials and the subsequent highly satisfactory performance in service, of the new cruisers *Gustav V* and *Drottning Victoria* of the Swedish Navy, have served to renew the interest which these vessels aroused when their construction was first proposed.

These two ships were contracted for before the war, but due to the unsettled conditions during, and immediately following hostilities, they were not completed until early in 1922. The final trials of the *Drottning Victoria* were run in June, 1921, and those of the *Gustav V* in January, 1922.

The hull of the *Gustav V* was constructed at Kockums

Mek, Verkstads Aktiebolag in Malmo, Sweden, and that of the *Drottning Victoria* at the works of the Gotaverken in Gothenberg, Sweden. The turbines for both vessels were built by the Aktiebolag Lindholman-Motala at Motala, Sweden, in accordance with designs furnished by the Westinghouse Electric and Manufacturing Company, and under the supervision of their representative. The gears were designed and built by the Westinghouse Machine Company at East Pittsburgh, Pa.

PRINCIPAL DIMENSIONS

Draft designed	20 feet 6 inches
Speed, maximum, knots.....	22.5
Shaft horsepower at maximum speed...	22,000
Propellers, number	2

Fig. 1.—General Arrangement of Propelling Machinery

Fig. 2.—Showing Steam Path Through Turbines

Fig. 3.—Diagrammatic Plan of Piping and Valves

The armament in each case consists of four 11-inch guns mounted in turrets forward and aft, eight 6-inch guns in the secondary battery, six 12 pounders and two submerged torpedo tubes. The normal complement is 408 men.

The propulsive equipment is located in two engine rooms amidship, each of the twin screws being driven by two turbines of the divided-flow type. The speed reduction is accomplished by means of two-pinion single-reduction double-helical gears. Vacuum is maintained by means of rotary air pumps and condensate pumps. The operating conditions are:

Steam pressure at turbine...265 pounds per square inch gage
Quality.....Dry and saturated
Vacuum in exhaust.....28.27 inches referred to 30-inch
barometer

The total weight given above is 63,065 pounds less than the total specified in the guarantee.

The general arrangement of the propelling units in the ship is illustrated in Fig. 1. Fig. 2 shows the steam path through the turbines, and Fig. 3 shows diagrammatically the piping, valves and maneuvering arrangements.

The divided-flow principle may be explained briefly as follows:

Turbines of low capacity are generally complete expansion units; i.e., the steam is expanded from inlet to exhaust pressure in a single cylinder. When the capacity exceeds certain limits, which vary with different manufacturers, the expansion must be split up, for structural and other reasons, and carried out in two or more cylinders. Where this is done

Fig. 4.—Chart Showing Guaranteed Steam Consumption

The steam consumption guarantees were as tabulated below:

Speed in knots (approximate)...	22.5	20	12.5
R.P.M. propeller	200	177	115
R.P.M. turbines	3,600	3,186	2,070
S.H.P. (designed)	22,000	15,000	3,150
Water, lbs. per SHP/HR.....	10.9	11.1	13.3

The designed maximum ship speed was 22.5 knots at 7,000 tons displacement for which it was estimated that 22,000 shaft horsepower would be required. On trial the *Drottning Victoria* maintained the contract speed of 22.5 knots at 6,950 tons displacement with 19,750 shaft horsepower. On the high speed trials of the *Drottning Victoria*, both the speed and the fuel consumption guarantees were bettered by considerable margins and the trial performance of the *Gustav V* was equally satisfactory.

The machinery weights per ship, as actually built, are as follows:

4 turbines	101,948 pounds
2 reduction gears.....	169,034 pounds
Piping valves, etc.....	19,942 pounds
Total pounds	290,924
Total tons (2,240 lb.).....	129.9

the two or more turbines comprising the unit may be used in series or in parallel. If they are used in series, all the steam passes first through the high pressure turbine, and the exhaust is led to the inlet of the low pressure turbine, which exhausts to the condenser.

These turbines, however, are in parallel. All the steam passes first to one turbine, (A, Fig. 2) nominally designated as the high pressure. After all the steam has passed through the first or impulse stage of this unit it is divided and while about 40 percent of the total continues on through the reaction stages of turbine A the other 60 percent is carried over through a cross-over pipe to the so-called low pressure turbine (B, Fig. 2) where it is expanded through reaction stages down to exhaust. Thus both turbines exhaust to the condenser and develop equal power, but one exhaust end handles 40 percent and the other 60 percent of the total steam. This is what is known as the divided-flow type.

PARTICULARLY SUITED TO NAVAL VESSELS

This type of turbine is particularly suited to the purposes of a naval vessel inasmuch as a high efficiency can be maintained over a considerable range of speed without resorting to the additional complication of a cruising turbine.

Fig. 5.—Section Through High Pressure Turbine

The results obtainable with this type machine are shown in the water rate curves given in Fig. 4. The method of procedure in operating at various powers is as follows:

When steaming at full speed the steam path is as described in the preceding paragraph. At reduced speeds, however, the cut-out valve between the high pressure and low pressure turbines is closed, see Fig. 2, causing the steam to flow through the reaction blading of the high pressure turbine only, the low pressure turbine meanwhile revolving idly in high vacuum, or being disconnected if the reduced power is to be maintained for a considerable period.

This arrangement improves the economy at cruising speed since a small turbine is used at full or nearly full power, instead of using both turbines at reduced power. The reduction in area for the flow of steam consequent upon cutting out the low pressure turbine improves the pressure distribution and increases the efficiency of the turbine. The blading of the high pressure element is also especially designed for efficient operation at cruising speed, extra rows of blades being provided. Since the low pressure turbine is used only at approximately full speed, its blading is arranged for this condition only, less rows being required than would ordinarily be the case. This design also permits a high speed of rotation, thereby reducing the weights considerably. In

case of emergency either turbine may be used independently of the other, making complete break-down a remote contingency. Furthermore, since the turbines have a great overload capacity it would be possible, in case of emergency, to develop three-fourths or more of full load power with one turbine only.

One of each pair of turbines is equipped with an astern turbine in the same casing, which is capable of delivering 41 percent of the ahead power with the same steam flow, or 9,000 shaft horsepower at full power.

DESCRIPTION OF TURBINES

The ahead high pressure turbine consists of a two-row impulse wheel followed by reaction blading on a drum as shown in Fig. 5. The ahead low pressure turbine, which is illustrated in Fig. 6, contains reaction blading only. The astern turbine is located in the exhaust chamber of the high pressure ahead turbine and consists of a single two-row impulse wheel.

The cylinder of the low pressure turbine is made entirely of cast iron. The cylinder of the high pressure turbine is made in two sections, the low pressure end being of cast iron and the high pressure end, which contains the nozzle chambers, being made of cast steel.

Fig. 6.—Section Through Low Pressure Turbine

The rotors of both turbines are made of forged steel. In the high pressure turbine the impulse wheel is carried on a solid disk formed integral with the spindle end. (See Fig. 5.) The high pressure stages of the reaction blading in both turbines are carried on drums; the low pressure stages of the reaction blading in each case are carried on a solid disk, which in the high pressure unit is integral with the drum, but in the low pressure turbine is part of the spindle end. This construction is clearly shown in the assemblies, Figs. 5 and 6.

The impulse blades are machined of nickel steel and are secured in the rotor by a substantial tongue and groove construction. The reaction blades are made of drawn phosphor-bronze and are secured in dove-tail grooves by a positive mechanical interlock between blades, packing pieces and grooves. This construction is shown in Fig. 7. The ahead turbine nozzle chamber, shown in Fig. 5, is divided into compartments, each of which is provided with a group valve, hand operated from the maneuvering platform, for closing off part of the nozzles at reduced power. The steam thrust is partly balanced by means of balance-pistons of the labyrinth

Fig. 7.—Details of Reaction Blading

type located at the inlet ends of the high and low pressure turbines.

STEAM AND WATER SEAL GLANDS

The glands are a combination of the steam seal and water seal types, as shown in Fig. 8. The steam gland is sealed from an annular chamber in the usual manner. The water seal operates on the principle of a centrifugal pump, the impeller being provided with radial paddles or ribs which revolve in a chamber supplied with water at the periphery of the impeller. The centrifugal action of the paddles on the water in this chamber causes it to revolve and to form an annulus of water around the outer circumference of the impeller, thus forming a perfect seal against leakage of air.

The water seal is designed to be effective from full speed down to half speed. Below half speed the centrifugal force imparted by the impeller is not sufficient to maintain the seal and therefore, when cruising or maneuvering below half speed, or when standing by, it is necessary to use the steam gland. Steam is supplied to the labyrinth glands at a pressure of about 5 pounds per square inch gage. Water is supplied to the water glands at a pressure corresponding to a head of about 10 feet, the supply being taken from the feed water system through a suitably placed overhead tank.

The main bearings are of the self-aligning type and are provided with pads and liners for adjusting the position of the rotor.

The thrust bearing is of the Kingsbury segmental type

Fig. 8.—Steam and Water Seal Gland

and is provided with a screw adjustment for moving the rotor endwise for setting the dummy clearances.

The turbine shaft is connected to the flexible pinion driving shaft by means of a flexible pin coupling, which permits the pinion to move endwise. Provision is made for lubricating the coupling pins and bushings.

THE EMERGENCY GOVERNOR

Each turbine is fitted with a Westinghouse type emergency overspeed stop governor located at the thrust end of the machine, beyond the thrust bearing. This device consists of an eccentric weight held by means of a suitable spring and retainer in a hole drilled transversely in the shaft. In the event of overspeeding of the turbine from any cause, when the rotor reaches a predetermined number of revolutions per minute fixed by the relation of the spring scale and eccentricity of the weight, the centrifugal force on the weight becomes great enough to overcome the resistance of the spring and the weight moves radially outward. The relation of the parts is such that when the weight begins to move its centrifugal force increases more rapidly than the compression of the spring so that it at once moves out to the limit of its travel. In so doing it strikes a trip lever, located in the plane of its motion, the hardened end of which rests normally about 1/16 of an inch away from the circumference of the turbine shaft.

The displacement of this trip lever opens a valve which admits steam to the operating cylinders of the throttle valve and the auxiliary exhaust inlet control valve causing them to close.

The emergency stop governor may be reset by means of a

Fig. 9.—Floating Frame Type Reduction Gears

hand lever on the end of the bearing pedestal and as soon as it is reset balance is restored and the valves re-open automatically.

Just ahead of the governor valve in the main steam line is a steam strainer consisting of a cylindrical perforated steel strainer fitted in a cast iron body.

The admission of steam to the ahead and astern turbines is controlled by two single piston valves having circumferential ports and a pilot valve by means of which the pressure above and under the valve is equalized in the act of opening. These valves are placed on a stand at the after end of the gear case and alongside the main valves is placed the throttle valve for admitting emergency steam to the low pressure turbine. With this valve arrangement it is possible to operate either ahead turbine independently of the other in case of emergency. Nozzle control valves are furnished to permit the nozzle area to be adjusted to suit the operating conditions in order to maintain the best possible efficiency at all times. These valves are likewise located so that they may be opened or closed without leaving the maneuvering platform.

REDUCTION GEARS

The reduction gears are of the Westinghouse floating frame type as shown in Fig. 9. A Kingsbury segmental thrust bearing is located at the forward end of the gear, to take the propeller thrust. At the designed full speed the gears reduce the revolutions from 3,540 to 200, the reduction ratio being 17.23 to 1. Each pinion transmits 5,500 horsepower, the total for one gear being 11,000 horsepower.

The gears are completely enclosed in an oil-tight cast-iron box divided on a horizontal plane. The gears are of the double helical type, the teeth being inclined at an angle of 30 degrees. The teeth are of involute form and are cut with the utmost precision to obtain quiet and reliable operation.

The pinion is of the three-bearing type, as shown in Fig. 9, and is carried in a heavy floating frame supported on I beams, which automatically maintain the alinement of the pinion and gear under all conditions of load, thereby producing uniform distribution of pressure over the entire length of tooth face. The pinion is driven by a flexible shaft, see Fig. 9, which extends through it and is secured to the end distant from the coupling. The flexible coupling permits the pinion to move endwise, and the flexible shaft permits the floating frame to function without restraint. The resulting uniform

distribution of tooth pressure permits the use of higher pressures and smaller pinions and gears than is the practice where rigid bearings are used.

The pinions, Fig. 13, are single forgings of carbon steel. The gear wheels are composed of a heavy forged-steel shaft, cast-iron center and cast-steel rims. The gear and pinion bearings have heavy cast-iron bodies lined with white metal, and are supplied with oil from the main oiling system, the pressure at the inlet to the gear case being about five pounds per square inch. A copious supply of oil is sprayed on the pinion so as to pass between the meshing teeth and afford the required lubrication and cooling.

KINGSBURY THRUST BEARING

The Kingsbury thrust bearing, which takes the thrust of the propeller, is located at the forward end of the gear, and is composed of a single collar, which operates between segmental shoes made of forged steel and lined with babbitt. Each shoe is pivoted on a hardened seat, which permits it automatically to assume the position required to distribute the load uniformly over the entire surface. This uniform distribution of pressure due to the self-alinement of the shoes, gives perfect film lubrication, which permits the use of a considerably higher unit pressure than is used in ordinary thrust bearings, and also gives greater reliability of operation.

The principal parts of the bearing are made of forged and cast steel. The bearing is lubricated by a continuous circulation of oil, which is admitted near the bottom and completely fills the casing, the outlet pipe being led from the top of the casing and returning the oil to the drain system.

LUBRICATING SYSTEM

The lubrication of the main turbine bearings and the gear teeth and bearings is effected by a continuous circulation of oil through a pressure system composed of delivery and return piping, pumps, cooler, strainer and tank. Oil is supplied to the bearings and teeth under a pressure of about five pounds per square inch.

The turbines were constructed in Sweden as before mentioned and it speaks well both for the thoroughness of the design and the character of the craftsmanship of the Aktiebolag Lindholm-Motala, that the machinery was delivered without a hitch and has since established an enviable reputation for continuity of service and simplicity of operation.

The U. S. S. Colorado, the World's Mightiest Super-Dreadnaught

New British Marine Oil Engines Developed

Beardmore Builds Largest Semi-Diesel Ever Installed in Cargo Vessel—Richardsons, Westgarth Construct Modified Tosi Engine

By Our Special London Correspondent

UP to the present time, British shipowners have paid comparatively little attention to the possibilities of what in England is generally called the semi-Diesel or hot-bulb motor, for the propulsion of cargo ships. Considerable surprise was therefore evinced when it became known that Beardmores, the well-known Clyde shipbuilding firm, had produced two engines of this class, the largest ever constructed, for installation in a cargo ship of about 4,000 tons deadweight.

There are numerous vessels of this size, some of them quite recently built, and equipped with machinery of equal power, in which a Diesel plant is utilized, and it would thus appear that competition would now arise between semi-Diesel and Diesel engine builders in connection with ships of moderate tonnage. It is a curious fact that Beardmores are also manufacturers of ordinary Diesel motors, but the two types are constructed in separate works.

The ship referred to, which is now fitting out at Bristol, is 310 feet in length with a beam of 43 feet 6 inches, and the two new engines which are to be installed are designed to develop 750 brake horsepower, although the normal working output will be 600 brake horsepower. The largest semi-

Diesel motor that has hitherto been produced is of 500 brake horsepower and several of this type have been constructed by Bolinders, by the Kromhout firm, and by Vickers Petters.

A SAVING IN WEIGHT

There is a considerable saving in weight in the new Beardmore motor in comparison with the Diesel engine, since this amounts to only 45 tons, whereas with the latter design, the weight would probably be in the neighborhood of 80 tons. Presumably there is a corresponding reduction in capital cost, which is an important point since the average motorship costs between 15 and 30 percent more than a corresponding steamer. The bore and stroke are 18 inches and 24 inches respectively with a speed of 185 revolutions per minute for full power. As will be gathered from the illustration, the engine is of normal semi-Diesel type, so far as crank chamber compression is concerned, and this involves the construction of separate cylinder units, each with its own self-contained crank chamber, in which the scavenging air is compressed to about 3 pounds per square inch on the downward stroke, before being admitted to the cylinder through ports in the bottom. The

A 750-Brake Horsepower Semi-Diesel. The Largest of its Type Yet Built

The 10,000-Ton Motor Tanker Scottish Borderer

cylinders are cast separately, being flanged at the bottom for bolting on to the crank chamber, and at the top for the attachment by means of bolts of the water cooled cylinder cover.

ELECTRIC HOT PLUG

The "hot bulb," if it can so be called, is of special design, owing to the fact that the heating effect preliminary to starting, which is always necessary in semi-Diesel motors, is provided by an electric plug arranged in the top of the bulb and not by a blow lamp, which is the ordinary system. This plug, which projects into the combustion space is wound with a resistance wire, and when a current is passed through it, becomes sufficiently hot in about 20 seconds to allow the engine to start up. Thus the new motor suffers under little, if any, disadvantage in comparison with a Diesel engine in this respect.

Starting is accomplished by admitting compressed air to the cylinders through automatic non-return valves in the cylinder head, the necessary distribution being effected through mechanically operated distribution valves, arranged between the two sets of three cylinders. The six fuel valves are also located at this point and deliver through automatic valves, and it is to be noted that the timing of injection is the same for ahead or astern running, so that in reversing no alteration has to be effected. This process is therefore carried out by turning the starting wheel, which only controls the admission of compressed air. The engine represents a noteworthy departure and as the manufacturers are said to be contemplating building still larger sizes, the performance of the first vessel equipped with these engines may have some influence upon motorship construction—at any rate in the smaller types.

THE RICHARDSON TOSI ENGINE

In the year 1922, the largest output of reciprocating steam engines in the United Kingdom, was achieved by Richardson, Westgarth and Company of Hartlepool and Middlesbrough. The first marine Diesel engine built by this firm, therefore, possesses more than ordinary interest, especially as it has adopted a very conservative policy before developing along these lines. The twin screw installation has just been completed for a 6,000-ton Furness Withy motorship, and although the design is based upon that of the engines built by the well-known Italian firm, Tosi of Legnano, Richardson, Westgarth and Company have introduced a number of modifications. This has in fact been the case in practically all the Continental Diesel engines which have been taken up by British builders under license.

COMBINED VALVE FOR EQUALIZATION OF TEMPERATURE

The new Richardson-Tosi motor is of the four-cycle type with six cylinders, 24.41 inches bore and 38.39 inches stroke, the output at 120 revolutions per minute being 1,250 brake horsepower or 1,550 indicated horsepower with the rather high mechanical efficiency of 80 percent. In one feature, this engine differs from all other designs. The same valve is used for the admission of the air on the suction stroke, and the discharge of the exhaust gases; the control for the two purposes is effected by a semi-rotary valve which puts the combined valve first in communication with atmospheric air and secondly with the exhaust pipe. There are two of these combined valves in each cylinder cover so that there is more valve gear than with a normal design. It is claimed, however, that the equalization of temperature thus produced,

A Twin Screw Richardson-Tosi Installation for a 6,000-Ton Motorship

and the cooling of the valves by the incoming air, are advantages that warrant the extra expenditure, and the result is that the valve may operate for very long periods without having to be reground.

Another novelty is the system of reversing. Its chief object is to avoid having to move the heavy camshaft fore and aft as is commonly done. The reversing mechanism, therefore, merely lifts the valve levers off the cams, and then causes the rollers of the levers to move the necessary distance to bring them over the astern cams. Forked pieces are provided at the end of the valve levers, with a horizontal spindle, along which the rollers may move. Instead of operating the reversing mechanism by an air servo motor, a small electric motor is used for the purpose. One advantage of this arrangement is that there is a saving in compressed air. All the valves are arranged in cages and the valve levers are jointed in such a way that by uncoupling these joints, the valves can be removed from the cylinder head without dismantling any further gear.

POPULARITY OF MOTOR TANKERS

Tank ships are, of course, very suitable for propulsion by internal combustion motors, and it is notable that a large

proportion of the orders that have recently been placed for vessels carrying oil in bulk are to be propelled by Diesel engines. Among the latest contracts, are a 10,000-ton ship to be built by Armstrong Whitworths for a Belgian concern, and equipped with Sulzer type machinery of 2,700 brake horsepower, a 5,000-ton motor tanker with a Nobel Diesel two-cycle engine, of 2,000 brake horsepower, a 12,800-ton vessel for a Norwegian concern, to be equipped with 4,000 horsepower Werkspoor machinery, and a 6,500 tonner for Dutch owners, in which an 1,800 brake horsepower Harland & Wolff engine is fitted.

There has just been completed at Denny's yard on the Clyde, an interesting tanker, as she is the first vessel of this class to be fitted with British built Sulzer machinery. The *Scottish Borderer*, as she is named, is the fifth motor tanker constructed for the British Tanker Company, Ltd., and she carries 10,000 tons of liquid fuel. Two engines, of 1,250 brake horsepower each, with four cylinders are fitted, and, unlike most of these motors, drive their own scavenging pumps, the independent turbo-system not being adopted. A speed of 11 knots is attained on a fuel consumption of about 9 tons daily. The auxiliary machinery, contrary to usual practice, is steam driven.

Chemicals Endanger Carriage of Iron Goods

Smoke Helmets Sometimes Required to Enter Holds—Delayed Insurance Claims Causing Difficulties — Norwegians Fear Compulsory Insurance

By "Bordereaux"

IRON goods in transit often suffer serious damage through chemical influences. There has been considerable complaint, of late, of injury to consignments of such merchandise at Buenos Aires, the cargoes including iron wire, sheet iron, steel tubing, etc. It was at first supposed that sea water was the cause of the damage, but more complete examination made it appear most improbable that a ship could have stood up under such inroads of water as would have been necessary to have done the damage in evidence. Observation of steamers arriving at the South American port has led to the belief that the action of chemicals is properly chargeable with the results. It is now insisted that special care must be taken in stowage. Such corrosive chemicals as chloride of lime and acetic acid ought never be taken into the same holds with iron goods.

Captains and shipping agents too frequently try to conceal this sort of thing, but that only delays the employment of necessary remedies. It is stated that there are instances where stevedores, unloading cargo, have had their hands and clothing burnt because chloride of lime had fallen out of broken casks on the rest of the cargo in the hold; and, cases are cited where the holds could only be entered by men wearing smoke-helmets, because the vapors from broken jars of chemicals abounded and had seriously rusted all the iron goods in the holds. There is considerable business in the insurance of particular average, but unless the losses are infrequent there is no profit in it to the insurers. Checking of the stowage seems to be more important than surveys before loading.

Delayed Claims

THE late presentation of claims is one of the peculiarities of marine insurance and an element that contributes not a little to its difficulty. In the case of vessels, the repair of damages that do not disable the ship may be delayed for a long time if freights are good and the owners do not wish to lay the vessel up. Owners may delay the collection

of claims even when the repairs are made. Collision cases frequently involve prolonged liquidation extending over several years. Cargo damages often bring hundreds of consignees into the problem, with almost endless communications with parties scattered all over the world. During the war, these complications were enormously aggravated and the improvement to date has not been great. The framing of marine accounts, in consequence, becomes a matter of the utmost difficulty.

British Hull Values and Rates

IN England hull values and rates continue to be reduced under spur of violent competition. It is the old trouble—too much marine insurance facility and too little business. It is said that values as low as £2 have been fixed for recent cover. At no previous stage in its history has the British market quoted rates as low as it is now doing, especially as concerns the smaller type of vessel. Certainly, there is no justification in the claims experience for such action. A very large number of steamers have been renewed at values and rates below those that prevailed in 1914. It is hard to understand why underwriters will persist in so doing, especially when it is borne in mind that repair bills are still about fifty percent over pre-war cost; and the steamers are nine years older.

War Risk Award Reversed

THE war risk insurance award of \$280,105 granted the Standard Oil Company of New Jersey by the Federal District Court of that State has been set aside by the United States Circuit Court of Appeals at Philadelphia. The lower tribunal had held that the loss of the vessel, which was the tanker *Llama*, came within the terms of the policy. The *Llama* went down in Westray Firth, off the English coast, in October, 1915. She was en route to Copenhagen

and struck a submerged rock, stranding and subsequently sinking. The United States carried her war risk but payment was refused on the ground that her loss was not due to a war peril. Now the Court of Appeals rules that the vessel's loss resulted from a marine peril and to errors of navigation; not from a war hazard.

Cargo Rates for Munson Line

RECOMMENDATION has been made by the Underwriting Conference Committee that for rating purposes the Shipping Board owned steamers operated by the Munson Line out of United States Gulf ports to the East Coast of South America be granted the same basis of classification as the cargo boats operated by the Lamport & Holt Line in the same trade.

Hull Insurance in Norway

UNDERWRITING and shipping interests in Norway are greatly relieved that the new Norwegian cabinet, which came into office a few weeks ago, is to proceed no further with the compulsory insurance scheme fostered by a previous Government. The enforcement of this proposal was postponed one year ago, under stress of the unanimous opposition of owners and underwriters, to enable owners to effect a consolidation of the mutual insurance clubs. Since that time the number of these clubs has been considerably reduced and a consolidation and reorganization of those that remained has been effected. A claims office for the compilation of statistical data has been established and the insurance companies have joined it, and there has been a general revision of the insurance conditions of the mutual associations. In view of these improvements a general alarm went the rounds when it was intimated that the Government was to discuss discussion of the compulsory scheme in parliament. Happily, the Government has "seen a great light" and will drop the matter and let good enough alone.

Liability of Carrier

CCOURT definition of the legal responsibility of a carrier was given in an opinion recently handed down by the United States Circuit Court of Appeals, Ninth Circuit, in a libel in admiralty by the Willamette Navigation Company vs. the Hartford Fire Insurance Company, 287 Fed. Rep., 464. The navigation company undertook the transport of certain rolls of paper, by the steamship *Ruth*, under a bill of lading subject to the condition that the carrier should not be responsible for loss or damage resulting from "the perils of the lakes, seas, or other waters, or from collision, stranding or other accidents of navigation." The navigation company took out insurance with the Hartford Fire by open policy "for account of themselves, loss, if any, payable to assured."

The *Ruth* stranded and sank, and a quantity of the paper was damaged. The navigation company filed a libel against the insurance company to recover, under the policy, the amount in part of the loss and damage to the paper.

The Circuit Court of Appeals held that the navigation company, being a bailee for hire, whether as carrier or warehouseman, could lawfully insure the entire interest in the paper entrusted to its care for carriage or storage, and, if loss occurred, would be entitled to demand and collect from the insurer the entire amount of the loss sustained covered by insurance. However, in such case it would hold the excess above its own interest in the paper for the use and benefit of the owners of the paper, or others concerned therein.

In support of this holding citation was made of the case of the Munich Assurance Company vs. Dodwell & Co., 128 Fed. Rep., 410, in which it was said:

"We think that the true doctrine is that the carrier has an insurable interest in goods in his possession as such, to the full extent of their value, against a loss for which it is possible that he may become responsible, and that the question whether he has the right to recover under the policy is not to be determined after the loss by inquiring whether in fact he is then liable to the owners of the property for the value thereof or for damage thereto. . . . It had the right to insure against its own negligence, as well as against the necessity of being required to enter into the inquiry whether its own negligence caused or contributed to the stranding of the vessel."

Turning to the policy, the court expressed the view that the insurance being "for account of themselves," comprised a particular person; that is, the assured, to whom the loss is payable. Cooley's Briefs on Insurance was quoted: "The general rule is that a policy made in the name of a particular person will not protect the interest of any other person, unless the words 'for whom it may concern,' or their equivalent, indicate that it is intended that the interest of some other person be covered."

It was also shown by the authorities that a policy in the name of one joint owner of a vessel "as property may appear," without a clause stating the insurance to be for the benefit of all concerned, does not cover the interest of any other joint owner. It was further held that where the insurance policy issued to the carrier covered only the carrier's interest in the cargo, there could be no recovery thereon for the shipper's interest in the cargo, where the loss resulted from stranding of the ship, for which the carrier, under the bill of lading, was not liable to the cargo owner.

Excursion Steamers for Wilson Line

(Continued from page 535)

piston type fire and donkey pump suitable for a working pressure of 210 pounds. The pump cylinders are of cast iron heavily brass lined and brass fitted and are of the separate cylinder type. The steam valve gear is of the outside adjustable tappet type with link connection to cross heads, permitting of adjusting the stroke of pump while in motion.

There is one 4¼-inch by 4¾-inch by 5-inch vertical duplex piston pattern fresh water pump with cast iron pump cylinders, brass lined and brass fitted for fresh water supply to all lavatories, sinks and ice and hot water systems through a pressure tank on the boat deck.

There is one 6-inch by 6-inch by 8-inch vertical duplex piston pattern sanitary pump having a cast iron pump cylinder, brass lined and brass fitted. The steam valve gear of this pump is also of the outside adjustable tappet type with link connection to the crosshead. . . .

There are two 6-inch by 3½-inch by 6-inch horizontal duplex piston pattern special fuel oil service pumps, designed for 300 pounds oil pressure. The pump cylinders are of cast iron and are especially designed for fuel oil service.

For circulating brine on the refrigerating system there are two 4½-inch by 3¾-inch by 4-inch vertical duplex piston pattern pumps having cast iron pump cylinders, brass lined and brass fitted.

For ice water circulating, there are three 4½-inch by 2¾-inch by 4-inch vertical duplex piston pattern pumps with cast iron pump cylinders, brass lined and brass fitted.

The steam cylinders of all of the foregoing pumps are covered with 85 percent magnesia and lagged with planished iron, making a very neat finish.

A hot water circulating pump and heater are fitted for the hot water supply to the sinks, lavatories and showers throughout.

Protective Coverings for Shipbuilding Purposes: Paints—Bottom Compositions

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

BOTTOM compositions on steel ships have to fill two functions,—that of preventing corrosion and that of preventing fouling. This has led to the general practice of having the bottoms painted with two kinds of paint over the priming coat, the inner coating being called anticorrosive paint and the outer, antifouling paint. Corrosion is not a factor on wood ships but the antifouling paint on them has also to serve the purpose of preventing the attack of the teredo and other marine wood borers which honeycomb the wood. Corrosion is also not a factor on concrete ships; and as factors peculiar to concrete ship construction enter into the subject of bottom compositions for these vessels, this matter has been dealt with in the writer's article on "Cement and Concrete for Shipbuilding Purposes" in the June and July 1922 issues of this magazine. Furthermore some bottom compositions that adhere well to steel ships have not been found to adhere well to concrete.

The antifouling properties of the general run of antifouling compositions result from the use of a poisoning ingredient which is usually mercuric oxide in paints for steel ships and copper oxide in paints for wood ships. The latter composition is often called copper paint. Some copper paints also contain mercuric oxide. A very interesting series of tests of the toxic value of these chemicals, together with copper cyanide, copper acetate, copper chloride and mercuric chloride, have been made by Mr. A. W. L. Bray of Washington University, St. Louis, Mo.; and these tests indicate that copper cyanide would be very efficient in an antifouling paint. The copper acetate, copper chloride and mercuric chloride are probably so soluble in sea water as to afford a very brief protection. The solubilities are about as follows:

	Grams per 100 Grams of Solution.
Copper Oxide	Trace
Copper Cyanide	Trace
Mercuric Oxide	.05
Mercuric Chloride	12
Copper Acetate	13
Copper Chloride	47

The American Society for Testing Materials started out in 1921 to test the anticorrosive and antifouling properties of a great many compositions, which they applied to steel panels immersed in Raritan Bay, N. J., and also at Charleston, S. C. On a part of the panels anticorrosive paint only was applied. The poisons used in the antifouling paints were yellow mercuric oxide, mercuric arsenate, mercuric phenate, mercuric oleate, cupric oxide, cuprous cyanide, zinc cyanide and zinc stearate. These were added to a mixture of Spanish oxide, zinc oxide and asbestine to make a total pigment content of 40 percent, the vehicle being 60 percent in every case. Results reported at the annual meeting in June 1922 indicated the advisability of limiting further tests of antifouling paints to those containing copper and mercury compounds, and such further tests were decided

upon. Copper compounds alone or in mixtures with other poisons showed excellent antifouling properties in the Raritan Bay tests, but were not as satisfactory as the mercury compounds when immersed at Charleston, S. C.

There is also a type of antifouling composition which is of a saponifying nature, and a gradual sluffing off of the paint prevents the adhesion of marine growths.

ANTIFOULING PAINTS MUST BE FREQUENTLY RENEWED

The antifouling paints at the best do not retain their protective properties many months and hence vessel bottoms have to be repainted at regular intervals. There are, therefore large amounts of bottom compositions used, and as a result there are a number of proprietary bottom compositions on the market; and they are in many cases applied by their manufacturers, whether the vessel is at a shipyard or in drydock. As with all other materials, the extended results of actual service are of more value than theoretically excellent formulæ, laboratory tests, etc.; and having the former to fall back upon, the designer, owner or operator will usually approve the use of some proprietary composition with which he has had favorable experience and gives himself no further concern. Where a vessel has been coated with a satisfactory brand of bottom paint it is desirable to continue the use of the same compositions, or at least to use a brand closely resembling them; because considerable of the earlier paint will adhere and the film becomes gradually built up to a thick coating, the various layers of which should act together properly. A large user of bottom compositions will usually have an approved list of these paints. Such a list in this country for steel ships will be apt to include some of the following well known makes, and possibly others:

Red Hand	Leonard Miller
Federal	Germicide
McInnes	Amalgamated
International	Reliance
Newport News	

SPECIAL BOOTTOPPING PAINT

In addition to the anticorrosive and antifouling paints, there is a boottopping paint that is applied in the region between the light waterline and the deep load waterline. It is required for the reason that antifouling paints do not stand up well when alternately wet and dry, and also because the usual topside paint does not offer sufficient abrasive resistance to the action of the waves. Good practice on steel ships is to apply one or two coats of anticorrosive paint, as may be necessary, from the keel to the deep load line, one coat of antifouling from the keel to the light waterline and a coat of boottopping from the light waterline to the deep load line. On both steel and wood ships there should generally be a first coat of priming paint. The only exceptions to this are cases where a kind of bottom composition is used that is known to give better results with the anticorrosive paint applied to the bare steel.

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

REQUIREMENTS OF BOTTOM COMPOSITIONS

Essential requirements of bottom compositions, in addition to the fact that each coat should perform its particular functions, are that they can be applied rapidly and will dry rapidly. In many cases a vessel will go into dry dock, have the bottom cleaned and painted and be out again the same day. It is desirable that the antifouling paint differ somewhat in color from the anticorrosive paint, so that failure to properly coat any portions of the surface can be readily detected.

The poisoning element in antifouling paint is heavy and tends to settle to the bottom of the container and even to the bottom of buckets used while applying it. It is therefore necessary to stir it up thoroughly and frequently.

About 20 years ago the U. S. Navy Department began testing a number of different anticorrosive and antifouling paint mixtures at the U. S. Navy Yard, Norfolk, Va., with a view toward developing a paint of their own; and the results of this investigation together with a lot of valuable information about bottom compositions are given in an article by Mr. N. E. Adamson, assistant shop superintendent of that Navy Yard, in the August and September, 1922, issues of this magazine. The formulæ of the antifouling and anticorrosive paints there given show the characteristic composition of these paints, and the uses and values of the different ingredients are very clearly set forth by Mr. Adamson, who also points out the possibility and desirability of having one kind of paint for both the anticorrosive and antifouling duties. The tests are not yet completed.

Of 21 formulæ first tested at the Norfolk Navy Yard, formula 17 for anticorrosive paint and formula 19 for antifouling paint gave the best results and were found to greatly exceed the merits of the proprietary paints compared with them. They have been adopted by the Navy Department, except as to the kind of alcohol, and are as follows:

Quantities Required for 1 Gallon		
	Anticorrosive	Antifouling
Grain alcohol	3 qts.	4 pts. 3 gills
Gum shellac, Grade A.....	13 oz.	1 lb. 8 oz.
Turpentine	2 gills	3 gills
Pine Tar Oil.....	2 gills	3 gills
Zinc Oxide, dry.....	3 lbs.	1 lb. 8 oz.
Zinc dust	1 lb.	x
Indian red, dry.....	x	1 lb. 8 oz.
Mercuric oxide, dry.....	x	12 oz.
Weight per gallon	11 lbs. 8 oz.	10 lbs. 8 oz.

These formulæ were adopted by Dr. P. H. Walker of the Bureau of Standards and Dr. H. A. Gardner of the Institute of Industrial Research in the paint specifications prepared by them in 1917 for the U. S. Shipping Board Emergency Fleet Corporation, except that the grain alcohol was denatured by the addition of 5 gallons of approved wood alcohol to each 100 gallons of grain alcohol, the oxide of mercury was reduced to 8 ounces per gallon, and silica, to the same amount as the Indian red replaced it in the antifouling paint. Tests made by the Norfolk Navy Yard on modifications of the above formulæ had indicated that Indian red was not a desirable pigment for an antifouling paint and that better results would be obtained by the substitution of silica. Requirements of the Emergency Fleet Corporation specifications were as follows:

ANTICORROSIVE BOTTOM PAINT

The paint shall be furnished in prepared form ready for application. It shall be made of the ingredients in the proportions given. The shellac shall be thoroughly dissolved in the alcohol before mixing and milling with the other ingredients.

The zinc dust used shall contain not less than 90 percent metallic zinc as such, the balance consisting mainly of zinc oxide. The pigment portion of the paint shall be of such fineness that 98 percent shall pass through a 300 mesh screen.

The paint must be satisfactory in every respect, including body and freedom from objectionable settling or hardening in the can. The paint must have satisfactory working qualities, hiding power, drying value, and color. It must be resistant to sea water.

ANTIFOULING BOTTOM PAINT

The paint shall be furnished in prepared form ready for application. It shall be made of the ingredients in the proportion given. The shellac shall be thoroughly dissolved in the alcohol before mixing and milling with the other ingredients.

The paint shall be tinted with lampblack to a color approximately that of the low visibility gray for hulls, a color card for which is to be seen at each district office.

The paint must be satisfactory in every respect, including body and freedom from objectionable settling or hardening in the can. The paint must have satisfactory working qualities, hiding power, drying value, and color. It must be resistant to sea water and poisonous to marine growths.

BOOTTOPPING PAINT

The paint shall be a zinc oxide paint in a vehicle of best quality water resisting varnish, with volatile thinner, which may be either turpentine or mineral spirits, or a mixture of these, and liquid drier.

The paint shall contain not less than 35 percent by weight, of pigment.

The pigment shall consist of zinc oxide tinted to the desired slate color with lampblack. (Leaded zinc oxide may be used, but in any event the total pigment must contain not less than 93 percent zinc oxide.)

The vehicle portion of the paint should contain at least 40 percent varnish which should comply with the specification for Emergency Fleet Corporation Varnish, the balance to consist of linseed oil, drier, and turpentine or mineral spirits.

The paint must be satisfactory in every respect, including body, freedom from objectionable settling or caking in can, working qualities, hiding power, fineness, drying, color, gloss, and durability under alternate exposures to sea water and air.

These specifications were adopted in 1918 by the War Service Committee of the Paint Industry.

One of the shipyards has for a number of years manufactured Navy standard bottom paints to Navy specifications and used them on all of the Government vessels built at their plant. In recent years they have been under contract with the U. S. Shipping Board to furnish bottom compositions to Shipping Board specifications for several ports. The ingredients used and their amounts reduced to a per gallon basis are as follows:

Anticorrosive		Turpentine	
Alcohol	2.92 qts.		3.2 gills
Gum Shellac	12.8 oz.	Pine Tar Oil	3.2 gills
Turpentine	1.92 gills	Zinc Oxide	22.1 oz.
Pine Tar Oil	1.92 gills	Indian Red	22.1 oz.
Zinc Oxide	2.84 lbs.	Oxide of Mercury ..	12.0 oz.
Zinc Dust	.96 lbs.	Boottopping	
Antifouling		Spar Varnish	4.25 pts.
Alcohol	2.4 qts.	Drier	2.19 pts.
Gum Shellac	22.1 oz.	Mineral Spirits	.85 pts.
		Venetian Red	2.91 lbs.

This company for a number of years has also been manufacturing proprietary bottom compositions similar to the Navy standard paints but with some substitutions that enable them to be sold at little more than half the price of the Navy standard paints. These include the use of rosin oil varnish instead of shellac and alcohol, and part turpentine substitute instead of all pure turpentine, in the anticorrosive paint, and the use of some coal tar naphtha in both the anticorrosive and antifouling paints. The boottopping paint is practically the same as above given. The manufacturers are in a position to observe the results of actual service of these compositions, in comparison with the Navy standard compositions, which gives considerable weight to their claims for these proprietary paints.

Antifouling paints which contain copper as the poisoning element have generally been considered undesirable on steel ships on account of the galvanic action set up between steel and metallic copper when in salt water which results in a rapid corrosion of the steel. However, some proprietary paints of this kind are often used on steel ships. One of these has approximately the following analysis:

		Anticorrosive	Antifouling
Pigment		40%	60%
Vehicle		60%	40%

Zinc oxide	7.5%	11.0%
Iron Oxide	32.0	24.5
Copper Oxide	x	22.0
Talc	x	2.5
Quick drying varnish	37.5	20.0
Pine tar and naphtha.	23.0	20.0
	100.0%	100.0%

A test made on a submerged plate, referred to by Mr. Adamson, in which cuprous oxide replaced the mercuric oxide in the Norfolk Navy Yard paint, showed after five months a film that was harder and more free from rust than the standard film, although it also showed that the copper paint would not prevent barnacles from becoming attached to the steel. The safer plan, however, is to use the mercury paints on steel. Copper paints are favored for wood ships.

Specifications for copper paint adopted by the U. S. Shipping Board Emergency Fleet Corporation for their wood ships are as follows:

The paint shall contain finely ground natural iron oxide. This oxide shall contain at least 40 percent Fe_2O_3 . It shall also contain copper oxide in amount sufficient to insure not less than 12.5 percent by weight, of copper in the completed paint.

The total pigment shall be not less than 44 percent, by weight, of the paint.

The non-volatile vehicle shall be not less than 30 percent, by weight, of the paint. The paint must dry satisfactorily to a tough salt water resisting film. It must have satisfactory working qualities, freedom from objectionable settling or caking in can, must be suitable for use on wood bottoms and have good antifouling and protective properties. The bottom of the vessel up to the light water line will have three coats of Standard Copper Paint.

Specifications prepared in 1918 by the War Service Committee of the Paint Industry followed the above very closely. They were as follows:

Pigment 44 percent.

Liquid 56 percent.

The pigment portion shall consist of finely ground natural iron oxide. This oxide shall contain at least 40 percent Fe_2O_3 . It shall also contain finely ground copper oxide in amount sufficient to insure not less than 12.5 percent of copper (Cu) in the completed paint.

The liquid portion shall consist of pine tar oil, drier and suitable thinners. The non-volatile liquid shall be not less than 25 percent of the paint.

Special requirements: The paint shall dry satisfactorily to a tough salt water resisting film and shall be suitable for use on wood bottoms and have good antifouling and protective properties.

One of the proprietary copper paints on the market has as its ingredients rosin oil varnish, coal tar naphtha, Venetian red and oxide of copper.

As with bottom compositions for steel ships, there are a number of proprietary paints on the market that have proved their worth in actual service; and the designer, owner or operator will usually find it to his advantage to approve the use of one of these paints. Approved lists may be expected to contain such brands as:

Woolsey	Cape Cod
New Jersey	Newport News
Baltimore	International
Cape Anne	Davis

Some of the proprietary paints contain more copper than called for by the above stated formula, and should be expected on that account to give better protection. Although the formula contains the amount of copper called for by the Navy Department and they have found after testing and examining a large number of paints of various formulæ that their paint with $12\frac{1}{2}$ percent metallic copper fully met their requirements, the very best copper paint is none too good a protection in some waters.

Three coats of copper paint of good quality may be expected to afford good protection for a period of about six months against marine wood borers although complete metal or wood sheathing is the only certain protection. Cementing the seams is of value in this connection. Wood ships should not be laid up in salt water, if it can be avoided, although

northern waters that have not in the past been infested with marine wood borers are reasonably safe.

Auxiliary Vacuum Pumps Used to Advantage

ABOUT three years ago one of the 12,000-ton Lake freighters was having considerable difficulty in maintaining proper vacuum, particularly while maneuvering in and out of port. Incidentally, this difficulty is not by any means uncommon. However, a remedy was found for the trouble in this case.

This particular ship had a ballast pumping installation consisting of two 14-inch centrifugal pumps and two reciprocating pumps for drainage. The pumping installation had been made with a connection from the condenser to the manifold so the engineer on the ship, as an experiment, started up the ballast pumps to see if they would help the vacuum any. He found a decided gain, especially when in maneuvering it was necessary for the engine to turn over slowly. Soon after this, an auxiliary air unit, consisting of two radojets, was installed and these, in conjunction with a turbo tail pump, are used for port service and at sea, if for any reason it is necessary to shut down the main air pump and also when an additional vacuum is desired for maneuvering. This auxiliary system can be operated at about 75 percent of the capacity of the main pump.

In general this system has been so satisfactory that all new vessels built for the steamship company on which the first unit was tried out will be equipped with radojets and a turbo pump as the main unit and not for auxiliary service alone.

NEW INTERCOASTAL SERVICE.—The Intercoastal freight and passenger service recently announced by the United American Lines will be opened by the steamship *Sudbury*, which will sail from Baltimore on September 8 and from New York, September 13. Fourteen modern vessels will operate in a weekly service between Baltimore and New York, Los Angeles Harbor, San Francisco, Portland, Seattle and Tacoma.

Famous North Pole Ship Becomes a Tug

The *Roosevelt*, famous exploring ship which carried the expedition of Admiral Robert E. Peary to the North Pole in 1909, and which has lain idle in Puget Sound for several years, has been purchased by a barge company and will be converted into a sea-going tug. The *Roosevelt* was built in Portland, Me., in 1905, and was associated with all the exploring expeditions of Admiral Peary. In 1915 the Government purchased the vessel and used it for several years in the Coast Guard service. The *Roosevelt* has a solid oak ice crusher bow, 24 feet thick. When the carpenters finish with her she will be one of the staunchest and most powerful tugs on the Pacific.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Life of Chain Cable

Q. (1,210).—Chain cables must be renewed when $\frac{1}{8}$ thickness in diameter has worn out. If so, how many years are chain cables good for resistance against the corrosion of salt water—any accidents being out of the question? K. S.

A. (1,210).—This question can only be answered in a general way because very little trustworthy information upon the subject is available. First class wrought iron chain may be considered to have a life of about ten years. The distorting and stretching of the links of the cable by excessive strains during proof tests and service eventually result in failure to engage the wildcat lugs properly. Probably this is as often the cause for its discarding as is the wastage due to corroding.

Most Economical Steam Pressure at Engine

Q. (1,211).—We have a twin screw job developing 2,200 indicated horsepower at 130 revolutions per minute, the high pressure valves cutting off approximately 64 percent of the stroke, and boiler pressure at 150 pounds, and throttle full open. For certain reasons we have cut the revolutions per minute down to 115, and I cannot shut the high pressure link in far enough to give me the required speed with throttles full open; I put a liner 1-inch thick back of the drag link brasses, but even that is not enough, and they will not stand any more.

My problem is this: Which is the most economical way of running (a) to use full boiler pressure and throttle to the required revolutions; or, (b) to cut down boiler pressure to give the required revolutions and run with throttles full open. In our case 135 pounds boiler pressure will give the required revolutions.

The proper way of course is to run at full boiler pressure, throttles full open and link up, or put lap on valve and advance sheave, but I cannot do this at present, so I have to do the next best thing. I cannot find any definite information in any of my books and would like this matter discussed, and the reasons for and against.

A. (1,211).—It has been found from experimental trials that it is not so economical to carry high steam pressure on the boiler and throttle down to the pressure required, as it is to carry the boiler pressure at about 25 pounds above that desired in the high pressure chest. In the case of a triple expansion engine the boiler pressure can not be dropped much below 100 pounds. A still lower desired pressure in the high pressure chest makes throttling necessary. Several factors enter into the making of this limiting pressure of 100 pounds.

Should there be a reducing valve in the auxiliary steam line the main steam could not be lower than its setting. Again, such auxiliaries as generators, main feed pumps and fire room blowers may begin slowing down to the point where they will fail to function properly even though no ill effects are shown in the running of the main engine.

High boiler pressure with a fireroom force of little experience has the advantage of requiring less careful attention in holding conditions constant and insures a safe steam reserve for maneuvering, but it has the disadvantage of increasing the heat loss by radiation and water loss from leakage. While throttling may produce some superheat, yet it will not be sufficient in amount to be of material value.

Reducing Valve in Steering-Engine Steam Line Dangerous

Q. (1,212).—Is there any economy in installing a reducing valve in a steering-engine steam line, where we are at present running under 150 pounds pressure, the reduced pressure to be say 65 or 70 pounds per square inch? Please give reasons.

A. (1,212).—Steering engines are constructed to take steam the full length of stroke, and the drying or slight superheating of the steam on the low pressure side of the reducing valve would have no economical value. Inasmuch as you are operating the steering engine on boiler steam it is probable that it was designed for high pressure and would not function properly on low pressure steam. Aside from this, the installing of a reducing valve introduces an element of danger. When a steering engine is wanted it is wanted badly. Should for any reason the valve fail to operate and the steam be cut off, a more or less serious casualty to the vessel might result. A relief valve and steam gage should always be fitted on the low pressure side of the reducing valve, and there should also be a by-pass connection around the valve.

Fuel Oil Consumption

Q. (1,213).—In good practice, what is the average consumption per indicated horsepower with fuel oil? Is 1.78 pounds of oil per indicated horsepower for all purposes excessive?

A. (1,213).—The fuel oil consumption per indicated horsepower varies not only with the power and service of the vessel in question but with the skill of the operating personnel, the tightness of joints, the condition of the vessel's bottom as to foulness, weather, etc. The following figures are based upon what may actually be expected under average service conditions covering a long period of time and not upon what might be expected under fairly good conditions, and may therefore seem somewhat high.

Deadweight Tonnage	Indicated Horsepower	Pounds Oil per Indicated Horsepower, all purposes.
3000 to 4500	1000 to 1200	1.75 to 1.6
5000 to 6000	1500 to 1800	1.6 to 1.5
7000 to 8000	2000 to 2250	1.5 to 1.4
8000 to 9000	2400 to 2800	1.4 to 1.30
9000 to 10000	2800 to 3000	1.30 to 1.25
10000 to 12000	3000 to 3600	1.25 to 1.20
Over 12000 (tank steamers)	4000 to 6000	1.20 to 1.15
Intermediate liner		1.15 to 1.10
Large passenger liner		1.15 to 1.10

Use of CO₂ Recorders

Q. (1,216).—Is the CO₂ recorder used to any extent in marine work in the United States, and who supplies these instruments?

A. (1,216).—The CO₂ recorder is not used to any great extent in the merchant service, but it is believed that engineers are beginning to see its value more and more as a fuel saver.

Among those manufacturing CO₂ recorders may be mentioned: The Chadburn (Ship) Telegraph Company of America, Inc., Troy, New York; The McNab Company of Bridgeport, Conn.; Foxboro Company, Foxboro, Mass., and Schaeffer and Budenberg Manufacturing Co., New York.

LETTER TO THE EDITOR

Combined Riveting and Welding

Referring to the editorial in the July issue of MARINE ENGINEERING AND SHIPPING AGE under the above heading, the writer is in favor of combined riveting and welding where such construction is not too expensive.

We still have considerable to learn about welding, but there is no question but that welded joints will hold when they are properly made. The writer has had experience with both kinds of welded joints—those that hold and those that let go. The principal objection to the welded joint is the old so-called "personal factor" which is present but not to the same extent in the riveted joint. Besides, the welded joint does not lend itself so readily for inspection and testing. It is easy for a poor welder to "cover up" his poor welding.

It has been demonstrated in the making of tanks that the addition of welding is beneficial for two reasons—first, it makes the joint stronger, and, second, it makes the joint leakless and calking becomes unnecessary.

As for the questions which are asked, "Will a combination of riveting and welding work in unison or will the weld which unites the metal in one piece take the entire load and the elastic limit of the joint be reached before the rivets begin to work?" This question can hardly be answered positively because so much depends upon the nature of the weld. If properly done, there can be but little question that the weld and the riveting will act in unison, but there is no telling in advance or possibly even after the welding is done that the two will work in unison and we must "take a chance" just the same as we are taking chances right along even with riveted work, and for which we use a factor of safety in nearly all engineering practice. By carefully annealing the welding after it is finished it is quite probable that the welding and riveting will act in unison. If the welding is not annealed, the chances are that there will be some internal stresses and both the riveting and the weld will be stressed somewhat due to the initial welding stresses and even before the load is applied. This is not alone "theory"—it has been proved in practice.

As for the second question—"If riveting cannot be depended upon for such a connection why not make an entirely welded joint?" The answer is already partially given. Neither joint is absolutely dependable. Nothing is absolutely perfect. But by both welding and riveting the joints we have a "duplication" which is usually desirable for the same reason that two pumps on boilers are desirable, two main steam lines in the power plants, two boilers, two engines, etc. To my way of thinking a joint that is both riveted and welded is more dependable than one that is only riveted or only welded. Some exhaustive tests on this subject are surely needed by the engineering world.

New York.

N. G. NEAR.

PERSONAL MENTION

M. C. JACKSON has been appointed general superintendent of the Philadelphia-Norfolk Steamship Company, with headquarters at Norfolk.

M. M. VIPOND, known among the shipping men of the Port of Norfolk for many years as the special deputy collector of customs, has assumed the title of Assistant Collector of Customs.

A. W. DAVIDSON, former representative of the United American Lines at Hamburg, Germany, has assumed the

duties of marine superintendent of the United American Lines at 39 Broadway, New York.

W. K. SEMPEY, formerly with the China Mail Steamship Line, has been appointed general freight agent of the Los Angeles Steamship Company, succeeding G. C. Foster, resigned, and will have headquarters at Seattle.

JAMES T. STEWART, formerly superintending engineer for the Army Transport Service at Brooklyn and Hoboken, has accepted the position of assistant port engineer for the Division of Operations, U. S. Shipping Board, New York District.

E. H. WEATHERSPOON, marine electrical engineer, has opened an office at 149 Broadway, New York, and will act as eastern representative for manufacturers of marine equipment, including the Charles J. Henschel Company, Inc., of Amesbury, Mass., electrical engineers and manufacturers.

JAMES GEISTMAN has been appointed general manager of the Marine Iron & Shipbuilding Company, boiler makers, shipbuilders, machinists and foundrymen, foot of Eleventh Avenue West, Duluth, Minn. John Abernethy is general superintendent, B. J. Roberts, assistant superintendent and John Sinclair, repair superintendent.

H. J. WAGNER has been formally installed as traffic commissioner of the Norfolk and Portsmouth Freight Traffic Commission. H. V. C. Wade, who prior to the organization of the Commission was traffic manager of the Norfolk-Portsmouth Chamber of Commerce, is assistant traffic commissioner of the new body.

W. A. MILLER, formerly port engineer of the Baltimore Steam Packet Company, at Baltimore, has been appointed by W. L. Seddon, vice-president of the company, as superintendent to succeed the late Captain J. H. Delano. Mr. Miller has been with the Old Bay Line for several years and is thoroughly familiar with the position.

J. S. MAHOOL has been appointed traffic manager of the Panama-Pacific Line of the International Mercantile Marine Company, which will resume service, interrupted in 1915, between New York and California. For the past three years Mr. Mahool has been assistant general manager of the Red Star Line in Antwerp. He is a native of Maryland, and has been in the service of the International Mercantile Marine Company since boyhood. His headquarters will be at 1 Broadway, New York, and he will have charge of both passenger and freight business of the coast to coast line. The ships selected to open the new service, the first sailing of which is scheduled for October 18, from New York, are the *Kroonland*, *Finland* and *Manchuria*.

FREDERICK W. COWIE, consulting engineer of the board of harbor commissioners of Montreal, has been appointed expert advisor of the Hampton Roads (State) Port Commission. The immediate duties of Mr. Cowie will be to aid the state commission in preparing a report and recommendations to the next General Assembly of Virginia, visualizing the future of Hampton Roads as a state asset, and showing how the state will be benefited by participation in its expansion and its development. Mr. Cowie has spent thirty-six years with the St. Lawrence Ship Channel and board of harbor commissioners of Montreal, being chief engineer of the latter from 1907 until last year. During his term in that capacity he supervised the construction at Montreal of what is considered one of the most successful terminal projects in the east. The terminals are self-supporting and are building a surplus. Included in recent work Mr. Cowie has done on the Atlantic seaboard are surveys and reports, with recommendations on the harbor of Boston and a comprehensive plan on the development of Savannah as the state port of Georgia.

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

Southern Pacific Asks Bids for New Passenger Vessel

PRELIMINARY plans and specifications have just been completed by the Southern Pacific Company for a combined passenger and freight ship and sent it to various shipyards for estimates on the cost of construction.

This vessel, which is to be used in service between New York and New Orleans, will probably be followed by a second vessel, the plans for which are now being considered by the company. Bids submitted for the present vessel will be taken under consideration for further action about September 30.

Estimates have been made by the shipbuilding companies, to whom plans have been submitted, on a vessel 445 feet length overall, 427 feet length between perpendiculars, beam 57 feet, depth to hurricane deck 37 feet 6 inches, draft 25 feet 6 inches, with a deadweight tonnage of 7,000 at this draft. She is to be a single screw vessel, driven by double reduction geared turbines of 6,000 brake horsepower. The vessel will be capable of a speed of 15½ knots. Steam will be supplied at 250 pounds pressure by six oil-burning watertube boilers, at about 75 degrees superheat.

No efforts will be spared in making this vessel one of the most luxurious of the ships in coastwise service. Cabin arrangements allow for commodious lounge rooms, dining salons and promenade decks. She will be fitted to carry 237 first class passengers and 111 steerage passengers.

City of Los Angeles to Be Reconditioned

It is reported that the steamship *City of Los Angeles*, formerly the *Aeolus*, operated by the Los Angeles Steamship Company between West Coast ports and Honolulu, is to be reconditioned and fitted with new boilers and propelling machinery. Bids have been submitted on turbines for the vessel by various builders of marine engines. Prices have also been given on a single and double reduction gears by one of the gear manufacturers.

Captain Pillsbury, of Pillsbury & Curtis, San Francisco, Cal., is carrying on negotiations for boilers with oil burning equipment for this vessel. Work on the refitting of this vessel will necessarily include structural changes in the bunkers to accommodate them for carrying fuel oil.

O. Tug to Be Rebuilt

FORMATION has been received by MARINE ENGINEERING AND SHIPPING COMPANY that the Standard Oil Company of New York has decided to practically rebuild tug No. 1 of the New York fleet. The tug, which is 100 feet in length, will require new boilers.

American Marine Association Announces Plans for the Third Annual Exposition Nov. 5-10

THE American Marine Association will hold its Third Annual Marine Show in the Grand Central Palace, New York City, during Marine Week, November 5-10. This is the same week that the American Marine Congress will convene in New York, so that the combination of the two will beyond a doubt bring to New York the greatest marine gathering ever held anywhere in the world.

Practically every person interested in ship operation, building, repairing and allied lines will be present at that time, as the success of their business depends to a great measure on what is done by the Congress.

On the other hand, New York will be full of manufacturers, farmers, producers and shippers, who have things to ship in our vessels. They are coming with a view of bettering their business operation, namely, securing more profitable and advantageous ways of shipping their goods.

Much can be shown to these people by the marine fraternity, through the Marine Exposition.

This interest has never before been displayed in shipping affairs, so the committee in charge of the Marine Exposition this year feels that it has become in addition to its present function a matter of transportation in all its phases.

Transportation facilities will be highly developed in the Exposition; harbor, ports, terminals and shipping projects will be shown, together with all modern and economic handling facilities.

The committee in charge of the Exposition has been named and is as follows:

Edward A. Colson (chairman), chief operating engineer, Babcock and Wilcox Company.

J. Tiebout, Jr., Secretary, W. & J. Tiebout.

G. E. Lawrence, Sales Agent, Bethlehem Shipbuilding Corp.

R. C. Burnside, President, Asbestolith Mfg. Co.

C. Van Zandt, Gen. Mgr., Fire Detecting Wire Corp.

A. Schlueter, President, New Process Chemical Co.

F. W. Sterling, President, Sterling Cooper Corp.

P. S. Thorsen, President, P. S. Thorsen & Co.

Gardner Cornett, President, Pneumercator Co.

H. M. Lee, President, Lee and Simmons.

W. A. Reynolds, Field Engineer, Lunkenheimer Co.

H. Seip, New York Representative, Adams and Westlake Co.

G. E. Barker, Manager Eastern Zone, Crane Company.

R. B. Lea, Manager Marine Dept., Sperry Gyroscope Co.

John T. Borden, New York Manager, Sun Shipbuilding Co.

The chairman, Edward A. Colson, reports that already approximately 60 percent of the available exhibit space has been reserved.

Marine Congress to Foster Diesel Engine Development— Committee Organization Outlined

IN a recent interview with K. Warren Heinrich, secretary of the American Marine Association, which organization has called the American Marine Congress for November next, it was learned that one of the important activities of the Congress will be to determine upon effective ways and means of fostering Diesel engine development in this country.

To accomplish this end, a Diesel engine committee has been established, the chairman of which is Rear Admiral William S. Benson, U. S. N. (Retired), commissioner of the United States Shipping Board, Washington, D. C.

Admiral Benson is recognized as one of our foremost authorities on Diesel engine development, and he is noted for the unflagging interest he has always taken in the development of the motorship. Under his leadership it is confidently expected that the efforts of this committee will be most productive.

Admiral Benson has given much thought and study to an organization plan for such a committee, and it is learned that his proposed organization, as outlined here, has

met with the approval of those charged with the direction of the American Marine Congress:

CHAIRMAN: Rear Admiral W. S. Benson, U.S.N., (Retired), commissioner of U. S. Shipping Board.

EXECUTIVE SECRETARY: K. Warren Heinrich, secretary of American Marine Association.

GENERAL COMMITTEE: To include representatives of all the various fields of activities in the marine and stationary field of internal combustion engines, auxiliaries, and electrical appliances.

EXECUTIVE COMMITTEE: To include a few selected from the general committee and to be men actually engaged in the development of the industry and nationally known for their active interest in the matter.

The following is a list of the classifications of the various groups to be represented, together with the names of the various persons who have been selected for membership in this important committee. Some of those whose names are given have been extended invitations to accept places on this committee, and the others will receive their invitations as soon as they can be prepared and forwarded. In some cases the representatives of various companies have not yet been selected, and in those cases the name of the company is given, it being the

intention to confer with each company in question and have them designate their representatives:

GROUP (A) Manufacturers of marine Diesel engines: A. B. Homer, Bethlehem Shipbuilding Corporation; Max Rotter, Bush-Sulzer Bros., Diesel Engine Company; M. P. Fillingham, Falk Corporation; A. Ballin, McIntosh and Seymour Corporation; New London Ship and Engine Company; Wm. E. Groesbeck, New York Shipbuilding Corporation; Robert Haig, Sun Shipbuilding and Dry Dock Company; J. F. Metten, William Cramp and Sons Ship and Engine Building Company, and others.

GROUP (B) Manufacturers of small Diesel engines for propulsion or auxiliary purposes: Atlas Imperial Engine Company; G. H. Jernberg, Fairbanks, Morse and Company; S. B. Abrams, Ingersoll-Rand Company; H. G. Trout and Company; Knudson Motors; Mid-West Engine Company; Winton Engine Works; M. L. Katzenstein, Worthington Pump and Machinery Corporation; Union Gas Engine Company.

GROUP (C) Manufacturers of marine auxiliary and electrical equipment: G. H. Jett, Allan Cunningham Company; P. E. Kriebel, American Engineering Company; E. W. Niven, General Electric Company; F. L. Andrews, Hyde Windlass Company; Western Electric Company; W. E. Thau, Westinghouse Electric and Manufacturing Company; W. S. Wilkinson, Bethlehem Shipbuilding Corporation.

GROUP (D) Shipyards and ship repair plants: Bath Iron Works; Federal Shipbuilding Corporation; Louis R. Ford, Morse Dry Dock and Repair Company; J. F. Nichols, Newport News Shipbuilding and Dry Dock Company; New York Harbor Dry Docks Company; J. S. Milne, Todd Shipyards Corporation; Vulcan Iron Works; W. and A. Fletcher Company.

GROUP (E) Manufacturers of miscellaneous appliances specially applicable to motorships. (Note: No appointments to be made in this group at present.)

GROUP (F) Manufacturers of stationary Diesel engines: Nordberg Manufacturing Company.

GROUP (G) Ship operators: No representatives have been selected in this group, but it is understood that they will be selected from the following: Baltimore Steamship Company; C. H. Sprague and Son; Luckenbach Steamship Company; Mallory Transport Line, Munson Steamship Lines, Tampa Inter-Ocean Steamship Company. Standard Oil of New York, Standard Oil of New Jersey, United American Lines.

GROUP (H) Advisory Group: A. S. Hebble, Chief engineer of the Southern Pacific Company Lines, New York; Carl E. Peterson, naval architect, United States Lines, New York; Phillip Shore, president, Tampa Inter-Ocean Steamship Company, Tampa, Fla.

Full and complete information concerning the activities of this committee will be given from time to time by the press.

Morgan Yacht Corsair to Be an Oil Burner

WORK has just been commenced on the conversion of J. P. Morgan, Jr.'s, yacht *Corsair* as an oil burner, at the Tebo Yacht Basin Works, Brooklyn, N. Y., of the Todd Shipyards Corporation. The installation of new equipment and necessary structural changes will take about two months for completion.

The arrangement of coal bunkers in the *Corsair* is such that it will be necessary to tear down the present bulkheads and install oiltight bulkheads in their place, it being necessary to have three tanks on each side of the vessel to hold fuel oil for the cruising radius required.

BOILER EQUIPMENT

The yacht is fitted with two double end Scotch boilers with three furnaces each, so that twelve fuel oil burners will be used in the installation. The Todd system of fuel oil burning will be used. Additional equipment necessary to complete the work will be two duplex pumps and four fuel oil heaters.

The *Corsair*, when fitted for coal burning, made use of a closed stokehold with blowers located on the upper deck. Natural draft will be employed in the present installation.

Chief Executives of Six Cities to Serve on Delaware River District Committee of Coming Marine Congress

THE mayors of six cities have consented to serve on the Delaware river and Pennsylvania district committee of the American Marine Congress, to be held in New York, November 5-10, according to latest announcement. The district committee, the personnel of which is now virtually complete, is as follows:

Honorary Chairman, Hon. J. Hampton Moore, Mayor of Philadelphia, Pa.; district chairman, W. P. Smith, of the William Cramp & Sons Ship and Engine Building Company; Hon. Frederick W. Donnelly, Mayor of Trenton, N. J.; Hon. Victor King, Mayor of Camden, N. J.; Hon. William T. Ramsey, Mayor of Chester, Pa.; Hon. George W. K. Forrest, Mayor of Wilmington, Del.; Hon. William A. Magee, Mayor of Pittsburgh, Pa.; George F. Sproule, Director of Wharves, Docks and Ferries of Philadelphia; J. S. W. Holton, President, Philadelphia Maritime Exchange; Emil P. Albrecht, President, Philadelphia Bourse; Edward F. Henson, First Vice-President, Philadelphia Board of Trade; William R. Tucker, Secretary, Philadelphia Board of Trade; Charles P. Vaughan, President, Philadelphia Chamber of Commerce; J. H. Mull, President, William Cramp & Sons Ship and Engine Building Company; H. A. Magoun, Vice-President, New York Shipbuilding Company; E. M. Herr, President, Westinghouse Electric & Manufacturing Company; H. T. Herr, Vice-President, Westinghouse Electric & Manufacturing Company; John G. Pew, Presi-

dent, Sun Shipbuilding Company; H. B. Vansciver, Superintendent, Merchants & Miners Transportation Company; E. Lavino, President, Lavino Shipping Company; John Hazelhurst Mason, Chairman of the Board, Bank of North America; Gal-lowsay C. Morris, Vice-President, Insurance Company of North America; Charles E. Mather, of Mather & Company; S. M. Vauc-lain, President of the Baldwin Locomotive Works; James W. Rawle, President The J. G. Brill Company; W. J. Conlen, of Conlen, Acker, Manning & Brown; E. B. Hill, Vice-President, Bethlehem Shipbuilding Corporation; *W. G. Coxe, Vice-President-General Manager, Pusey & Jones Company; *Charles E. Davis, Jr., Manager Gailey, Davis & Company; *Charles Delaney, President, Kensington National Bank; *John Frederick Lewis, of Lewis Adler & Lewis. (Those indicated by * are considered practically certain of acceptance.)

STANDARDIZATION COMMITTEE

It is further announced that the Standardization Committee will be composed of the following men:

Captain R. D. Gatewood, chairman; A. E. Bouillon, Director of Simplified Practice Department of Commerce; E. H. Riggs, Naval Architect of the New York Shipbuilding Corporation; H. G. Smith, Vice-President, Bethlehem Shipbuilding Company; A. W. Whitney, Chairman, American Engineering Standards Committee; Captain C. A. McAllister, American Bureau of Shipping; William F. Gibbs, Naval Architect; C. F. Bailey, Engineering Director, Newport News Shipbuilding Company; William S. Brown, President, Marine Engineers' Beneficial Association.

OTHER ACCEPTANCES

Definite acceptance of the invitation to serve as chairman of the Great Lakes District Committee, covering Minnesota, Wisconsin, Michigan, Northern Illinois, Northern Indiana and Northern Ohio, has been received from F. C. Bradbury, of the Cra Company, Chicago, Ill. Similar action with regard to other committees has been given out as follows:

H. H. Raymond, President, the City Steamship Company, is chairman of the Coastwise Shipping Committee; Robert Alter, of the American Tool Works Company, Cincinnati, O., chairman of the Manufacturers' Committee; William H. Kell, of the Flower Lighterage Company, New York, chairman of the Towing & Lighterage Committee; Admiral William S. Benson, Washington, D. C., chairman of the Diesel Engine Committee; R. H. M. Robins, President, United American Lines, chairman of the Steamship Owners' & Operators Committee, and George Carey, Secretary, Omaha Chamber of Commerce, Omaha, Neb., chairman of the Agricultural Committee.

PLANS DEVELOPING

Rapid strides are reported in the work out of plans for the Congress, interest in forthcoming event having already become nation-wide. State, municipal and city bodies, in addition to national organizations throughout the country have signified their intention of taking an active part in the deliberations.

Offers Made for Purchase of the President Arthur

INFORMATION has been received that negotiations are under way for the purchase of the *President Arthur*, operated by the United States Lines, by the Los Angeles Steamship Company through Pillsbury & Curtis, San Francisco, Cal., acting as agents for the line. The *President Arthur* is desired to replace the *City of Honolulu*, recently burned, which was used in the service between Los Angeles and Honolulu.

If the negotiations are successful, the vessel will be reconditioned at a cost of approximately \$500,000. Of this sum \$250,000 will be spent in the boiler room in fitting new boilers and remodeling the coal bunkers for the carriage of fuel oil. It was decided to fit this vessel with oil burners when it was found that the coal bunkers could easily be changed to carry oil fuel.

The present boiler installation includes three single end and three double end Scotch boilers, which have been in service since the ship was built. It is understood that these will be replaced with boilers of the watertube type. It will also be necessary to fit new uptakes to the boilers and most of the present piping will have to be replaced to provide for the changes in the same generating plant. New condensers will also be installed.

In addition to the changes in the boiler and engine rooms, it will be necessary to completely recondition the third class passenger accommodations.

Ocean Shipping Improving; High Costs a Drawback

THAT the ocean shipping situation is improving is disclosed by recent reports of the Transportation Division of the Department of Commerce. It is difficult for ship operators, confronted with the task of making revenue from unusually low rates, to balance with, and perhaps exceed, operating costs, which are still high. Yet fundamental factors, the Commerce Department finds, have become more favorable during the last year.

In the 12 months ended June 30, 1923, the idle steam tonnage of the world declined 2,443,200 gross tons. Of this decrease 1,694,502 gross tons were put into employment during the first six months of this year. The fact that idle tonnage has declined more rapidly in the last half of the past 12 months indicates that the slowly improving overseas trade of the world is gaining momentum. Furthermore, ocean freight (trip charter) rates apparently reached bottom in the last quarter of 1922 at 109 percent of the average for 1913. In the first quarter of 1923 the index rose slightly to 109.8 and stood at 109.5 for the second quarter. While the increase is almost infinitesimal it is significant that there was an increase.

Idle tonnage in British ports decreased from 1,667,000 gross tons on July 1, 1922, to 1,063,500 gross tons on July 1, 1923, but increased 53,500 tons over the tie up tonnage on January 1, 1923. Greece and Australia show an increase in idle tonnage in their ports during the year. On the other hand, the idle fleet of the United States Shipping Board decreased by 155,000 gross tons, and the privately-owned American vessels out of employment on July 1, 1923, were approximately 55,000 gross tons less than on July 1, 1922. Japan, Denmark and Spain show a decline of over 50 percent in vessels tied up in their ports on July 1, 1923, as compared with the year ended July 1, 1922.

Admiral Line Plans Building New Coastwise Liner

IF reports from Seattle are true, the Admiral Line has had plans drawn for a new vessel for their coastwise passenger service. The ship will have accommodations for seventy more passengers than the steamer *Admiral Schley*, of the same line, and will have a speed of about 15 knots. It is said that if the plans for the construction are let, the proposed liner will be one of the finest afloat in the coastwise service anywhere in the world.

Bids for Derrick Boat Hulls

The U. S. Engineer Office, Louisville, Ky., will receive bids about September 25 for six steel derrick boat hulls, 34 feet by 16 feet. Alternate bids on two and on four hulls will be asked. The hulls will cost \$5,000 to \$15,000 each.

To Build New Equipment

Keystone Sand & Supply Company, of Pittsburgh, Pa., plans to spend nearly \$100,000 on new equipment, including one sand digger and one large all-steel tow-at.

Specifications Issued for One and Two Coastwise Ships for the Old Dominion Steamship Line

PLANS and specifications for the construction of one and two passenger and freight ships for the Old Dominion Steamship Line, of which H. B. Walker is president, have been issued from the office of Theodore E. Ferris, naval architect and marine engineer, and bids were received on August 27. It is believed that if two ships are built it will involve an expenditure of approximately three and a quarter million dollars.

The proposed vessels are to be of the 3-

deck, hurricane deck, coastwise type, 375 feet 6 inches in length by 53 feet beam, 20 feet 6 inches depth, with a draft of 17 feet 9 inches. Accommodations are to be provided for about 322 first-class passengers, 58 steerage (white and colored) and 289 immigrants. The ships, which will be about 2,100 deadweight carrying capacity, will be driven by turbine engines with reduction gears, steam being supplied by four Scotch boilers. The engines are to develop 4,750 shaft horsepower and all the auxiliaries are to be driven by steam.

Newport News Shipbuilding Co. Low Bidder for Construction of Two Type "B" Steamers for Clyde Line

THE Newport News Shipbuilding Company, of Newport News, Va., is the low bidder for the construction of two passenger and freight ships for the Clyde Line although no definite contract has been signed as yet, according to information obtained by MARINE ENGINEERING AND SHIPPING AGE. While no official announcement regarding prices has been made it is understood that the contract will involve slightly under two million dollars for each vessel, these figures being for the construction of the "B" type or smaller size steamer.

The "B" type ship, according to the specifications, which were prepared by Theodore E. Ferris, is to have a length overall of

402 feet, beam molded 54 feet, designed load draft 18 feet and a speed of 15 knots. This type of ship is also to have passenger capacity for between 252 and 306 first class and 86 steerage passengers.

Prices were submitted for two type "A" ships, each having a length overall of 425 feet 6 inches, driven by turbine engines, and two type "B" ships, equipped with either reciprocating or turbine propelling machinery.

Bids on the contract were received on July 23 and due to the absence of Clyde Line officials from the city no definite information could be obtained as to when a final contract would be signed.

Manitowoc Shipbuilding Corp. Awarded \$1,750,000 Contract for Construction of Two Steamers

THE contract for the construction of two new steamers for the Pere Marquette Railroad, to be used on Lake Michigan, has been signed with the Manitowoc Shipbuilding Corporation, at Manitowoc, Wis. Delivery of the first vessel is promised for March and the second to follow in four months, the outlay involving an expenditure of approximately \$1,750,000. When these two ships are completed the railroad's fleet on Lake Michigan will comprise seven vessels.

The specifications for the new steamers provide for an overall length of 360 feet, depth of hold 21 feet 6 inches, depth at center—main to shade deck—17 feet 7 inches, depth at side 17 feet 4 inches, draft 16 feet. The hulls will be of single bottom construction with six watertight bulkheads through the lower hold space and the bows will be cut away for use in ice. Construction will

be of steel with two complete decks, the main deck having four tracks and being capable of carrying twenty-six 42-foot cars. Accommodations for passengers and crew will be on the shade deck, the passenger staterooms being equipped with double berths.

PROPULSION

The steamers will be propelled by two vertical, triple expansion, direct acting, condensing engines turning twin propellers. Steam will be supplied by four Scotch boilers, equipped for burning coal under the Howden forced draft system. With the engine turning 92 revolutions per minute and three of the four boilers in use, the boats are to develop a speed of 14 knots under ordinary service conditions.

The steamers will be electrically lighted throughout, the auxiliary equipment including wireless telegraphy.

Shipping Board Gets Two Piers

The two piers at the Army Base at Norfolk, Va., have been turned over to the Shipping Board, by an executive order of President Harding. No agreement has been reached thus far which will permit the transfer of the property to the city of Nor-

folk, the city having made a bid for the purchase of the base.

The Shipping Board now has the two piers in its custody and it is understood that if the base is sold there will be an arrangement whereby Government owned ships may have the use of the docks and service from the Belt Railroads.

Bids Open Sept. 7 for Construction of Six Steel Barges

SEALD proposals for the construction and delivery of six steel barges will be received by the United States Engineer Office, 321 Custom House, Portland, Ore., until 10 A. M., September 7. The boats are each to be 120 feet long, of 34 feet beam and 7 feet 6 inches depth, delivery to be at the government moorings, Linton, Ore.

Each boat is to be equipped with eight 36-inch cleats and four 30-inch open chocks, all of cast steel and of approved design, and two hand capstans of American Engineering Company type.

Bids September 10 at Montgomery, Ala., for 6 Steel Barges

THE United States Engineer Office, of Montgomery, Ala., will receive bids until 11 A. M., September 10, for three steel barges 80 feet by 26 feet by 5 feet and three barges 60 feet by 22 feet by 4 feet. One of the 80-foot boats is for delivery at Mobile, Ala.; two at Apalachicola, and the three 60-foot barges are for delivery also at Apalachicola. The boats are to be built with transverse oiltight bulkheads.

One of the three 60-foot barges is to be used as a pile driver hull and one as a drilling barge, certain fittings being required for each.

Bids Sept. 11 on Proposed 19-Barge Building Program

AS previously announced the U. S. Engineer Office, at Louisville, Ky., plans the construction of nineteen steel barges. The time for receipt of bids has been set at 2 P. M., central time, on September 11. The proposed boats are to have a length of 110 feet, beam 26 feet, depth 6 feet 5 inches. Four of the boats are to be built without cargo boxes, 15 with cargo boxes, delivery to be at the locks of the Louisville and Portland Canal, Louisville, Ky.

The time allowed for completion, including delivery, is as follows:

19 barges.....	216 days
15 barges.....	240 days
14 barges.....	240 days
10 barges.....	220 days
9 barges.....	210 days
5 barges.....	200 days
4 barges.....	200 days

New Nautical College

A charter has been granted by the State Corporation Commission in Richmond, Va., to the United States Nautical College, Inc., of Norfolk, under which name the institution will operate. The institution will have as its purpose the education of students in the management of ships.

The school will train students in the fundamentals of ship operation. Captain William J. Blue has been named as president; Charles H. Drummond, secretary, and Ella Blue, as one of the incorporators. The maximum capital was placed at \$5,000 and the minimum at \$1,000.

Steamship Typhon to Be Converted as Motorship

THE steamship *Typhon*, owned by the United States Shipping Board, has been purchased by the O'Boyle Lightering Company, 15 Moore street, New York City. The most important feature in connection with this transaction is the fact that the vessel will be converted as a motorship, and is to be equipped with a 750 horsepower McIntosh & Seymour engine.

Changes in propelling machinery will necessitate considerable reconstruction. Plans and specifications for the work, now available, have been prepared by Whittlesey & Whittlesey, naval architects, New York City.

The vessel has a length of 250 feet, beam 43 feet, depth 24 feet, and is of 3,400 tons deadweight at a draft of 19 feet. When completed, the vessel is expected to do about 9 knots.

It is estimated that three months will be required to complete the work, which will cost approximately \$200,000.

To Build Barges and Elevator

It is learned that the West Kentucky Coal Company, of Sturgis, Ky., plans to build several 600-ton coal barges, 136 feet by 26 feet by 9 feet, at its shipyard at Dubuque, Ky. The same company is also considering a \$25,000 addition to its coal elevator at Dubuque.

TRADE PUBLICATIONS

COMBINATION GRINDER AND BUFFER.—A pamphlet giving the structural features of the combination grinder and buffer made by the Hisey-Wolf Machine Company, Cincinnati, O., is being sent to the trade. This machine is adapted to work requiring the use of a grinding wheel, buffer wheel, wire brush wheel or rotary wire rasp wheel.

SHIP LANTERNS.—A circular describing a combination lantern applicable to ship service has been sent out by the V. & N. Lantern Company, 256 Broadway, New York. This lantern, it is claimed, is useful as a riding light and deck lantern. It has a white and a red lens, the latter readily adjustable at any time and in any wind.

AMERICAN LIT-O-SIL-O.—The steamship *Leviathan* is decked with American Lit-O-Sil-O and the Marine Decking and Supply Company, Philadelphia, Pa., has made this latest outstanding installation of flooring the subject of a special *Leviathan* pamphlet. In addition to details and photographs of the decks of the *Leviathan*, general information on Lit-O-Sil-O is given.

BOILER TUBES.—An announcement of the New York boiler tube supply service of B. F. Keating Company, New York City, has recently gone out to the trade. Complete stocks of steel, lap welded and seamless charcoal iron tubes, as well as fittings, valves, cocks and plumbing supplies are maintained in the New York district. The card also includes a number of reference tables giving tube data.

ELECTRIC HOISTS.—A book of illustrated economies describing the application of the Shepard electric "Lift About" featuring the slogan "an electric hoist for everybody," has

been prepared by the Shepard Electric Crane and Hoist Company, Montour Falls, N. Y. to demonstrate that Shepard hoists are applicable to practically every industry. The book also contains specifications and structural details of the "Lift About."

MECHANICAL SYSTEM OF OIL BURNING. The system of oil burning known as the "Dahl System" controlled in this country by the Bethlehem Shipbuilding Corporation Ltd., Bethlehem, Pa., is outlined in a catalogue now being distributed. The swinging type furnace front is described in detail with illustrations, specifications, and its application. The catalogue also contains a description of the Bethlehem line of pumps for handling oil.

INDUCTION MOTORS.—The construction and application of Type A-A Reliance Induction motors for two and three phase alternating current circuits have been made the subject of a special bulletin by the Reliance Electric & Engineering Company, Cleveland, Ohio. The bulletin is introduced with a short outline of the company's history, leading to the manner in which type A-A motors were designed. Specific details of the motor construction are then given.

CONTROL RELAYS.—Control Relays, to be interposed between the circuit breaker solenoid and control switches are described in bulletin No. 47672 issued by the General Electric Company, Schenectady, N. Y. The relays described are known as the instantaneous control type PB-53 and the hesitating control, type PB-54. These relays are used for the remote control of circuit breakers when it is undesirable to have the control current pass through the control switch.

MODERN FURNACE BUILDING.—The Jointless Fire Brick Company, 9899 Clay Street, Chicago, is offering to engineers and power plant operators a booklet which tells the complete story of the building of modern lithic furnace linings. It shows how boiler furnaces, circular furnaces, pit type brick furnaces and other furnaces may be lined with this jointless furnace lining. Illustrations showing how forms for special shapes, like front door arches, are made are frequent.

SHOP TROLLEYS.—A trolley folder has just been issued covering the new Yale trolleys. It is the first piece of literature to be issued on this equipment, and contains, in addition to detailed descriptions of the plate and geared types of the new Yale steel plate roller bearing trolleys, a description of the new Yale cast-iron trolleys. Incorporated in it are details of interesting trolleys to which the new steel plate trolley was subjected, and a complete list of the material handling equipment manufactured by Yale & Towne Manufacturing Company, Stamford, Conn.

INJECTOR TROUBLES.—Many companies manufacturing equipment both for marine and stationary service devote considerable time to the investigation of the possible ways in which their equipment may be caused to function badly and to develop the best service and maintenance methods to prevent such difficulties. In the case of the Penberthy Injector Company, Detroit, Mich., many requests from engineers using the Penberthy injector asking for help in locating troubles caused this company to send out a data sheet giving "Directions for Locating Injector Troubles." It is quite the most complete work of its kind and will prove invaluable to any marine or plant engineer who includes injectors in his equipment. This company will send copies of the pamphlet on request.

Foreign Shipping and Shipbuilding Activities

Italian Liner Launched at Ansaldo Yard

GENOA, Italy (Special).—The latest addition to the fleet of the Transatlantica Italiana was recently launched in the shipyards of the Ansaldo Company at Sestri Ponente, just outside of Genoa. The new liner is named the *Admiral Bettolo*, after a famous Genoese sea captain, and was christened by the Countess Bettolo. There were present at the launching many civil and military authorities, and officials of the Transatlantica Italiana.

The *Admiral Bettolo* is the product of Italian labor and Italian enterprise, and her engines and entire equipment are Italian. She is the third liner which the Ansaldo Company has built for the Transatlantica Italiana. She will carry a total complement of 1,375 comprising 68 first class passengers, 114 third class passengers and 197 members of the crew.

The vessel is 447 feet long, displaces 1,600 tons, and will be capable of a speed of about 16 knots. She will be equipped with 22 lifeboats, one a motorboat, and with a radio outfit of the most modern type. There will be a complete heating and ventilating system, contrived to serve, specially, the hospitals, the third class dormitories, and the stokers' quarters.

The total capacity of the coal bunkers is about 1,880 tons, sufficient for a round trip from Genoa to New York. Among the other features of the equipment are an up-to-date refrigerating plant, and an electric plant.

The new liner will go into service between Italy and South America.

Ellerman Vessel Launched on the Tyne

WALLSEND-ON-TYNE, England.—Built for the Ellerman Lines, Ltd., of Liverpool, the *Lesbian*, a steel single screw steamer, was successfully launched by Swan, Hunter & Wigham Richardson, Ltd., from their Wallsend yard on July 31. The vessel is 71 feet 4 inches long, 41 feet 6 inches beam and 23 feet 9 inches depth forward and 22 feet aft. She has a cruiser-shaped stern, a combined poop and bridge about 172 feet 3 inches long, also a topgallant forecabin of 40 feet, and is rigged as a two-masted fore and aft schooner.

The ship is being built to the highest class of Lloyds, is designed to carry about 1,425 tons on a draft of about 21 feet 3 inches, has three cargo holds with four large hatchways leading to same and eight cargo derricks. Water ballast will be carried in the double bottom, all fore and aft, and in the after peak.

A steel house amidships provides accommodation for the saloon, chief officer, apprentices and stewards, and above this is a steel house with the captain's room and chart room. The engineers and remaining officers are berthed in steel houses abreast the engine casing, the seamen, firemen and petty officers in the forecabin.

The ship is lighted throughout by electricity, and the accommodation amidships is steam heated.

France Taking Steps to Improve Shipping; Committees Appointed to Suggest Ways; Shortage of Orders Handicaps Shipyards

By Our Paris Correspondent

THAT France is making strenuous efforts towards a general improvement of the conditions of her shipping trade is shown by recent examples such as the appointment of special committees for the mercantile marine, the measures taken by the Government and the resolutions passed by several congresses and various trade associations and Chambers of Commerce. Both the Government and these associations have been endeavoring for some months to stir up the general opinion in this country in favor of the development of the merchant marine by pointing out the vital importance of the shipping trade for France.

COMMITTEES APPOINTED

The Government has recently appointed a committee of leading personalities in the trade and shipping circles with a view to investigating the actual position of the French merchant marine and making suggestions towards bringing about an improvement in the present conditions of the maritime commerce. This committee, the so-called "Commission Generale Extra-Parlementaire de la Marine Marchande" (General Extra-Parliamentary Committee for Merchant Marine), has already made energetic efforts towards a better utilization of French vessels and a more favorable position of French shipowners as compared to foreign shipowners. The principal schemes and measures which are about to be enforced, thanks to the remarkable activity of the Commission Extra-Parlementaire, are: The organization of joint committees constituted by representatives of shipowners and seamen which is intended to prevent the occurrence of all possible differences between employers and employees such as the strike of September, 1922, which entailed severe inconvenience for the country and losses for shipowners; and the organization of the "Credit Maritime," a régime of loans to shipowners which shall enable the latter to hold out until the prevailing difficulties have disappeared. At the same time the Commission is importing measures in order to reduce the imports of foreign materials or fittings used for the construction of vessels, so as to organize a "self-supply" scheme.

Although the position of the steamship companies has so far not been much improved as shown by the reports for 1922, it

A vertical donkey boiler is fitted for supplying steam to the winches, windlass and other auxiliary machinery.

The engines, which are of the ordinary inverted marine type with three cranks driving a single propeller, also the boilers, of which there are two single-ended ones for a working pressure of 225 pounds per square inch, will be placed slightly abaft amidships and are being built by the Wallsend Slipway & Engineering Company, Ltd., Wallsend-on-Tyne.

is hoped that following the real and extensive efforts made on this side the shipping trade will shortly recover from its uneasiness.

LIQUIDATION OF STATE FLEET

The final accounts in respect of the liquidation of the State fleet have been recently set forth by Mr. Charles Leboucq, a deputy for Paris. While the sum produced by the sale of the vessels owned by the Government since the war amounts to 190 million francs the total expenditure comprising the cost of vessels and the running expenses works out to 1,998 million francs, the liabilities thus amounting to 1,808 millions. Assuming that the amount of interest for four years and various other expenses and duties may be estimated at 740 millions, the total amount of the liabilities amounts to nearly 2,500 million francs. Such figures which represent an enormous sum are far beyond the most pessimistic conjectures which have been put forward in recent years in that respect and it may be anticipated that France is not likely to make any further experiment with a State fleet.

Interesting signs of a slight improvement in trade conditions may be found in the recent decision taken by the French line to establish fortnightly departures (in lieu of monthly) from Havre to the northern and southern Pacific Coast of America.

SHIPBUILDING OUTLOOK

The position of the shipbuilding industry in this country is still showing severe difficulties owing to the shortage of orders for new vessels. Several shipyards, which were about to fail, have been able to carry on work, thanks to orders for warships placed by the Navy. Orders placed by private shipowners have been growing fewer and fewer in the course of the last month and it may be stated that the Messageries Maritimes is the only steamship company which has an important building program under completion. The reason for this is to be found in the fact that this company is receiving the financial support of the Government according to an agreement entered into in 1921.

A big event which has been arousing many comments in shipping circles during the last few weeks is the non-renewal of the commercial "modus vivendi" which had been entered into between France and Portugal in order to establish special low rates for the customs duties in respect of goods imported from one country to the other. The measure was suggested by the French Minister of Agriculture with a view to protecting the interests of the wine-growers of Southern France by opposing the import of Portugal wines. Such development will cause a heavy prejudice to French shipowners by reducing or suppressing the return freight which was taken in Portuguese ports by their vessels on their homeward voyages from North Africa.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPS AND SHIPBUILDING

Tug Drydocked, Portland, Ore.—The tug Wallula has been lifted on the Portland drydock preliminary to her transfer to the Hammond Lumber Company.

Ship Work, San Francisco, Cal.—The General Engineering Company is very busy with miscellaneous ship work, including the steamer West Henshaw.

Steamer Drydocked, Cleveland, Ohio.—The steamer W. A. Rogers has been drydocked for repairs to twenty-seven damaged plates received as a result of grounding.

Plate Repairs, Etc., Cleveland, Ohio.—The barge I. L. Bell, which recently had her plates damaged and considerable internal damage as well, has been drydocked for repairs.

Steamer Reconditioning, Philadelphia, Pa.—The steamship Western Spirit was awarded by the Shipping Board to the Cramp Shipbuilding and Dry Dock Company for reconditioning.

Barge Contract Awarded, Fort Mason, Cal.—The Quartermaster, United States Army, Fort Mason, Cal., has awarded the contract for a wood barge to A. W. DeYoung, at a price of \$17,250.

Conversion to Oil, Staten Island.—The steamship Kermit, of the United American Lines, is being converted from a coal to an oil burner at the plant of the Staten Island Shipbuilding Company.

Power Boat Repairs, Baltimore, Md.—The power boat, W. J. Townsend, which recently received damage to her propeller and stern bearings, has been taken to the Woodall's shipyard for repairs.

Vessel Repairs, New Jersey.—The contract for general hull and machinery repairs to the steamship West Comak was awarded on August 7 to the Federal Shipbuilding Company, at a price of \$21,235.

Steamer Overhauling, Mobile, Ala.—The steamship Cabrille has been hauled out on the docks of the Alabama Drydock and Shipbuilding Company for hull repairs and also some boiler and auxiliary work.

Dredge Reconditioning, Charleston, S. C.—The Charleston Dry Dock and Machine Company has started work on the United States dredge Comstock, which consists of scraping and painting the bottom.

Steamship Overhauling, Boston, Mass.—The Atlantic Works, East Boston, has been awarded the contract for overhauling the steamer Wabash, of the Nawsco Lines. The work will occupy thirty days and cost \$16,356.

Annual Overhauling, West Coast.—The coastwise passenger and freight fleet of the Pacific Steamship Company will receive its annual overhauling, the work having been started with the reconditioning of the liner Admiral Schley.

Stern Frame Replacement, Oakland, Cal.—The Moore Drydock Company received the contract for replacing a broken stern frame on the Norwegian steamer Lulse Niesen, the work to cover a period of about twenty-two days. Price \$18,454.

Vessel Repairs, New York.—At the opening of tenders for damage and bottom repairs to the steamship City of Freeport, of the Tankers Corporation, on Wednesday, August 8, the Alderton Dry Docks, with a bid of \$10,500, received the contract for the work.

Wooden Scows, Nassau.—The Government of the Bahamas invites tenders for the construction of

two wooden dump scows, having a capacity of 800 cubic yards. Plans and specifications may be obtained from S. R. H. Beard, harbor engineer at Nassau.

Vessel Repairs, New York.—The contract for general repairs and betterments on the steamship Southern Cross has been awarded to the Morse Dry Dock & Repair Company at a price of \$22,000, following the opening of bids by the Shipping Board on August 8.

Seasonal Drydocking, Charleston, S. C.—The steamship Cliffwood has been taken to the drydock of the Charleston Dry Dock and Machine Company and the steamship Cody is expected on the docks in the very near future.

Steamship Survey, Oakland, Cal.—Survey of the French Line steamer Alaska, damaged recently in collision, has been made by the Moore Drydock Company, of Oakland, and it was found that the vessel will need a new stem, renewal of some frames and about twenty new plates.

Extensive Repairs, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation has been awarded changes and repairs on the Mexican steamer Korrigan III.; river boat San Joaquin, general repairs, and the tug Sea Queen, of the Red Stack fleet, for propeller installation.

Miscellaneous Work, Oakland, Cal.—The Moore Company is also working on the following contracts: Renewal of six furnaces in the boilers of the tanker San Joaquin, after which the vessel will be drydocked, and drawing the tailshaft and carrying out hull repairs on the steamer Isonomia.

Low Bidders, Derrick Hull, Mobile, Ala.—The Midland Barge Company, of Midland, Pa., with a bid of \$21,900, submitted the lowest price for the construction of a steel derrick boat hull, bids for which were received by the United States Engineer Office, at Mobile, Ala., on Monday, August 6.

Scows Ordered, Louisville, Ky.—The contract for the construction of six steel side dump scows, bids for which were opened by the United States Engineer Office at Louisville, Ky., on July 16, has been awarded the Dravo Contracting Company, of Pittsburgh, Pa. The Dravo Company's total bids for the boats was \$113,220.

Vessel Conversion, Baltimore, Md.—The Bethlehem Shipbuilding Corporation of Baltimore, Md., has been awarded the contracts for reconditioning the steamers Mount Carroll and Mount Clinton from passenger to freight carriers for the United American Lines, the price for each steamer being approximately \$32,725.

Low Bidder, San Francisco, Cal.—The General Engineering and Dry Dock Company submitted the lowest tender at the opening of bids for hull repairs to the steamer West Cactus, with a tender of \$959. The other bids were: Moore, \$975; Bethlehem, \$998; Crowley, \$1,270; United Engineering Works, \$2,081, and Smith & Scanlon, \$2,197.

Tanker Repairs, New York, N. Y.—The tank steamer Bethelridge, operated by the firm of Walker & Daly, has been awarded to the Clinton Dry Dock & Repair Company for drydocking, painting and bottom repairs, to cost about \$2,280. A contract on the same vessel was recently completed by the Atlantic Basin Works, totaling about \$2,800.

Shipyard Activities, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation, San Francisco, Cal., has received the following contracts: The Norwegian steamer Sinaloa, of the Latin-American Line, for inspection; State tug Governor Irwin, for extensive hull repairs; British tanker Placuna and tanker La Purisma, for miscellaneous repairs.

Shipyard Activities, Baltimore, Md.—The Bethlehem Shipbuilding Corporation has been awarded

the contract for repairs to the steamer West Arrow by the Shipping Board at a price of \$5,800. The steamship Morrirstown is on the Baltimore Dry Docks and the Maryland Dry Dock Company is completing repairs on the steamship West Isleta.

Derrick Boats Planned, Rock Island, Ill.—The Chief of Engineers, U. S. Army, has authorized the U. S. Engineer Office, at Rock Island, Ill., to have constructed two steel hull derrick boats, to be 7 feet long by 34 feet beam and 5 feet deep, each boat to have two watertight bulkheads and two spud wells. It is understood that bids will be canvassed shortly.

Bids for Pumps, New York.—Sealed proposals were received by the Superintendent of Lighthouses, Third District, Staten Island, New York, on August 16, for furnishing and delivering a 3-inch by 2-inch by 3-inch horizontal duplex fresh water pump. This pump is to replace a pump of similar size and the new pump must replace old one without alteration to present piping or foundation.

Drydocking Job, New York.—The toss of a coin decided the awarding of a drydocking job on the steamship Prusa, following the recent opening of bids by the Shipping Board. The Morse, Robinson, New York Harbor, Crane and Staten Island Shipbuilding Companies each bid \$255.65 for the work the Fletcher yard tender being \$300. On the "throw-off" the Crane Company took the job.

Steamer Launched, Newport News, Va.—The steamer City of Chattanooga was recently launched from the yards of the Newport News Shipbuilding and Dry Dock Company. The vessel is for the Ocean Steamship Company and is a 6,500-ton ship 400 feet in length. She will run between Savannah, Ga., and New York. Her sister ship, the City of New York, is now on the ways and will soon be launched.

Low Bidder for Derrick, Huntington, W. Va.—At the opening of tenders by the United States Engineer Office, Huntington, W. Va., on August 16, the Dravo Contracting Company, of Pittsburgh, Pa. was low bidder for furnishing and delivering a steel derrickboat for the Kanawha River. The proposal were: Dravo Contracting Co., \$25,870; Charles War Eng. Works, \$26,760; Penn Bridge Co., \$28,500; Midland Barge Co., \$29,700; Independent Bridge Co., \$31,000.

Oil Barge, New York.—Plans and specification for the construction of a 5,000-barrel steel oil barge for the New York Central Railroad have been issued from the office of J. W. Millard, 17 State street, New York City. Bids were received at the uptown office of the New York Central on August 23. The proposed vessel is to be 144 feet long, beam 22 feet, depth 11 feet. It is understood that the equipment will include the "R. & D." heating system.

Miscellaneous Repairs, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company, Mobile has been awarded the following contracts: Towbon Demopolis, engine overhauling, etc.; tug Pinquon for hull scraping and painting machinery and boiler work; steamship Normania, boiler work; tug Buzzard, electric welding and other boiler repairs; tug Nimrod, installing of two fuel oil tanks, etc.; and tug Marion, placing of new steel decking and various other repairs.

Shipyard Activities, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation has been awarded the following work: Standard Oil tanker Captain A. F. Lucas, general repairs; oil carrier William H. Doheny, general cleaning, painting and miscellaneous work; British tanker Placuna, of the Anglo-Saxon Petroleum Company, placing of rivets in the hull; American-Hawaiian carrier Oregonian extensive general repairs; the Arizonian, extensive reconditioning.

Pump for Standard Oil Barge.—The Northern Fire Apparatus Company, of Minneapolis, has received

he contract for rotary pump equipment on the new diesel-electric barge under contract with the Newport News Shipbuilding & Dry Dock Company for the Standard Oil Company of New Jersey. The boat will be the first on the Atlantic coast with almost complete rotary pump equipment. There will be three cargo and four auxiliary pumps, direct connected to Westinghouse motors.

Vessel Repairs, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation, of San Francisco, Cal., submitted the lowest tender for drydocking and repairing the United States Shipping Board steamer West Calera. The price bid for drydocking the vessel was \$1,700 and \$17,638 for repairs, with the highest bid for the repairs running approximately \$21,000. The West Calera is one of the five freighters being placed in spot condition by the Government, these vessels having been brought to San Francisco from Southampton Bay on the West coast.

Miscellaneous Repairs, Mobile, Ala.—The Alabama Drydock and Shipbuilding Company has also been awarded the following miscellaneous work: steamship Hulaco for repairs to machinery, overhauling and assembling of refrigerating machine, boiler work, etc.; the tug Marion for renewal of a number of bulwark plates and various other plates; steamship Gaston for drydocking, cleaning and painting and some propeller and engine work; reconditioning of the steamer Cattleya and the Texas company's steamship Louisiana, for examination of hull and scraping and painting.

Vessel Repairs, New York.—Recent contracts awarded the New York Harbor Dry Dock Company include: The Standard Oil tanker Somerset, the Export Steamship Company's steamship West Gotomka, the Norton Lilly steamship City of Madrid, the White Star steamship Gitano, the Tidewater Oil barge Tydol, and two Merritt, Chapman & Scott derricks. Bids submitted on the Somerset were: New York Harbor, \$11,899; Robins, \$12,656; Staten Island Shipbuilding Company, \$14,661. On the steamship West Gotomka the proposals were: New York Harbor, \$6,972; W. & A. Fletcher, \$6,900; Alderton, \$7,300; Shewan, \$7,500; Clinton, \$7,514; Morse, \$7,694; Crane, \$7,827.

Bids for Derrick Boats, Nashville, Tenn.—The Union Bridge Company, of Beaver Falls, Pa., with a price of \$58,900, was the low bidder for the construction of two derrick boats with derricks, at the opening of proposals by the United States Engineer Office, at Nashville, Tenn., on August 13. The proposed vessels are to have a length of 76 feet 6 inches, beam 34 feet, depth molded at gunwales 5 feet, the hulls to be built of steel, each having two transverse watertight bulkheads. The tenders submitted for the work were as follows: Penn Bridge Co., \$58,900; Midland Barge Co., \$64,000; Independent Bridge Co., \$67,900; Dravo Contracting Co., \$71,750; Nashville Bridge Co., \$89,940.

Vessel Reconditioning, San Francisco, Cal.—At the opening of tenders for the reconditioning of three vessels, the General Engineering and Drydock Company, of San Francisco, Cal., submitted the lowest bids. For the installation of an oil burning system on the Mexican Navigation steamers Washington and Bolivian, the prices submitted being for each ship, the bids were as follows: General Engineering, \$10,865; Hanlon, \$12,675; Main Iron Works, \$14,339; Moore Drydocks, \$19,750; Bethlehem Ship. Corp., \$21,465. The third bid was on the steamer West Henshaw, one of the five vessels withdrawn from the idle Shipping Board fleet to be put in "spot" condition. The following were the prices: General Engineering, \$17,505; Main Iron Works, \$17,965; Crowley Ship Co., \$21,311; United Engineering, \$21,735; Hanlon, \$21,820; Bethlehem Ship. Corp., \$22,591; Moore Drydocks, \$24,170.

SHIPYARDS AND DRY DOCKS

Shipyard Purchased, Seattle, Wash.—The Pacific Steamship Company has completed a purchasing deal of 25½ acres of the wartime shipyard of the Skinner & Eddy Corporation, known as the No. 1 plant, and will construct terminals for ocean shipping which will cost several million dollars. The plans provide for three large piers, warehouses of large capacity and a building for the general offices of the Pacific Steamship Company.

Merchant Yard Closed, Chester, Pa.—On September 1 the Merchant Shipbuilding Company's yard on

the Delaware River will be closed down permanently, due to the dullness in the shipbuilding industry and the determination of the Harriman interests to concentrate all their efforts in that line at the Cramp Yards, at Philadelphia. When the yard was first owned by John Roach the first four steel ships of the modern American navy were built, the Atlanta, Boston, Concord and Dolphin.

PORT IMPROVEMENTS

Coal Elevator, Paducah, Ky.—West Kentucky Coal Company, Sturgis, plans a coal elevator at the foot of Ohio street, here. \$25,000.

Grain Elevator, Louisville, Ky.—R. D. Reidling, 18th and Magnolia streets, plans rebuilding grain elevator recently destroyed by fire. \$40,000.

Seawalls, West Palm Beach, Fla.—An election was held on August 14 for the purpose of voting on \$100,000 bonds for seawalls. K. Riddle, city manager.

Contract Rescinded, Sanford, Fla.—The city of Sanford rescinded the contract for a pier and yacht basin. Will re-advertise. F. T. Williams, Sanford, engineer.

Canals, Caledonia, Minn.—Plans are being prepared for 4,700 lineal foot canals to take care of flood waters of Mouse River. \$266,250. W. W. Peterson, city engineer.

Harbor Improvements, Oshawa, Ont.—The Dominion Government, Ottawa, voted \$50,000 for harbor improvements here, hydraulic dredge work. K. M. Cameron, chief engineer.

Grain Elevator, Edmonton, Alta.—The Department of Public Works, Railways and Canals, Ottawa, plans grain elevator here, \$200,000. K. M. Cameron, acting chief engineer, Public Works.

Pier, Charleston, S. C.—Sealed proposals will be received by the Port Utilities Commission, Room 712, Peoples Building, for construction of Union Pier. H. M. Gallagher, general manager.

Grain Elevator, Halifax, N. S.—The Department of Public Works, Railways and Canals, Ottawa, plans a grain elevator here, \$200,000. K. M. Cameron, acting chief engineer, Public Works.

Contract Placed, Ottumwa, Ia.—Wapello County awarded the contract for a drainage ditch and improvements in Cedar Creek Drainage District to Rude & Wold, Pomeroy, at a price of \$35,281.44.

Wharf, Blind River, Ont.—The Department of Public Works, Ottawa, awarded the contract for reconstructing timber wharf, pile foundations, to T. P. Charleson, 179 Gilmour street, Ottawa, \$25,000.

Drainage Canals, Levees, etc., Rayville, La.—Tensas Basin Levee Association plans to build 75-mile drainage canals, levees, etc., to protect 1,250,000 acres in northeastern section of state. \$3,500,000.

Hydraulic Dredging, Sault Ste. Marie, Ont.—The Department of Public Works, Parliament Buildings, Ottawa, plans hydraulic dredge work in harbor here. \$60,000 bonds voted. K. M. Cameron, chief engineer.

Pier, Hamilton Beach, Ont.—The Department of Public Works, Parliament Building, Ottawa, voted \$50,000 bonds for pier (mostly wood construction) at Hamilton Beach. K. M. Cameron, chief engineer.

Landing and Facade, New Orleans, La.—The Board of Port Commissioners, New Court Building, will take bids about October for extending the Poland Street wharf, 400 feet long and 230 feet wide.

Pier, San Diego, Cal.—The City Council awarded the contract for Contract B, on Municipal Pier 2, comprising concrete apron wharf for mole type pier, to F. H. Doran, 3735 Seventh street, at a price of \$292,700.

Levee, Caledonia, Minn.—Houston County Drainage & Conservancy District 1, plans levee and pumping station. \$428,000. Central States Engineering Company, 602 Laurel Building, Muscatine, Iowa, engineers.

Grain Elevator, Tiffin, Ont.—The contract for a 2,500,000-bushel elevator at Tiffin has been awarded to Fegles Construction Company, Fort William, by the Canadian National Railroad Company, 230 St. James street, Montreal, Que.

Levee, Bridge Junction, Ark.—Sealed proposals were received on August 15 by the St. Francis Levee Board for 32,000 cubic yards of excavation in ditch construction work adjacent to levee in Lee County. H. N. Pharr, chief engineer.

Elevator, Vancouver, B. C.—Harbor Commissioners, 712 Pender street, West, awarded the contract for superstructure of addition to Elevator No. 1, reinforced concrete, to Pacific Construction Company, Ltd., foot of Salisbury Drive, \$350,000.

Grain Terminal Improvements, San Francisco, Cal.—The Board of Harbor Commissioners has approved of the letting of contracts calling for various improvements at the State Grain Terminal located at Islais Creek, aggregating \$23,600.

Shipping Platform, Pittsburgh, Pa.—H. H. Heinz Company, 1062 Main street, is having plans prepared by Hunting & Davis, engineers, Century Building, 2 and 3 story, 25 by 500 feet reinforced-concrete and steel shipping platform, Progress street. \$175,000.

Grain Elevator, Vancouver, B. C.—Harbor commissioners, 712 Pender street, West, awarded the contract for a super-structure and foundation for Elevator No. 2, reinforced concrete, to Northern Construction Company, 736 Granville street, \$1,450,000 and \$150,000 respectively.

Levee, Clarksdale, Miss.—The Board of Levee Commissioners, Yazoo Mississippi Delta, received sealed proposals on August 14 for enlarging 5-mile Ward Lake Levee containing 10,000 cubic yards of topping and 75,000 cubic yards of banquette enlargement. W. L. Head, chief engineer.

Coal Elevator, South Beloit (Beloit, Wis., P. O.), Ill.—Keeler Lumber and Fuel Company, 108 State street, Beloit, Wis., awarded the contract for a 60 by 100-foot reinforced-concrete and timber coal elevator, 36 feet high, here, to J. Cliff, Bluff street, Beloit, Wis. Engineer's estimate, \$30,000.

Canal Drainage, Senatobia, Miss.—Strahorn Creek Drainage District, Tate County, has awarded the contract for 12½ miles drainage of canals, including 410,680 cubic yards in main canal and 110,000 cubic yard laterals, to Canal Construction Company, McCall street, Memphis, Tenn., at a price of \$0.975 per cubic yard.

Contract Awarded, Vicksburg, Miss.—The contract for 4,200 lineal feet of sea wall containing 9,500 cubic yards of concrete, 450 tons of reinforcing steel, 4,200 feet of interlock sheet piling 10-20 feet long, has been awarded to Jefferson Construction Company, Q & C Block, New Orleans, La. Engineer's estimate, \$325,000.

Bulkhead, Indian River City, Fla.—Indian River City Town Site Corporation is having plans prepared for a 3,000-foot bulkhead, 400 feet out from meander line of Indian River, and a 600-foot causeway to connect with artificial island of about 5 acres, \$150,000. H. F. Williams, care Hotel Pines, Titusville, manager.

Harbor Improvements, etc., Ontario, Can.—The Department of Public Works, Parliament Buildings, Ottawa, plans harbor improvements at Port Stanley, \$50,000; Toronto, \$600,000; Fort Williams, \$192,000; wharf extensions at Pelee Island, \$31,000; wharf repairs at Windsor, \$3,500; Port Burwell, \$2,500. K. M. Cameron, acting chief engineer.

Dredging, New Jersey.—Sealed proposals were received on August 15 at the office of the Department of Commerce & Navigation, Trenton, for dredging a section of proposed inland waterway connecting Barnegat Bay with Manasquan River, Ocean County, at \$55,000. H. J. Sherman, engineer. V. Gelineau, State House, Trenton, director.

Dredging, Boston, Mass.—The United States engineer office received bids on August 30 for dredging in Beverly Harbor, Mass. The total estimated quantity of material necessary to be removed, exclusive of allowable overdepth, is 512,803 cubic yards; the maximum amount of allowable overdepth being estimated at 96,940 cubic yards.

Bonds for State Port, Georgia.—A bill providing for the issuance of \$15,000,000 in bonds for the creation of a state port at some point to be voted on by the people of Georgia was introduced in the

house of representatives recently. The bill provides for a vote of the people on the issuance of the bonds and also an election as to the best location for the port.

Port Surveys.—A survey of the ports of this country is being made jointly by the Shipping Board and the Board of Engineers. At present a complete survey of the Port of Norfolk and its terminal facilities is being made by Oliver Albert Reynolds, examiner of ports and terminals for the United States Shipping Board and the United States Board of Engineers for rivers and harbors.

Steel Structure, New Orleans, La.—The Board of Commissioners at the Port of New Orleans received sealed proposals at Suite 200, New Orleans Court Building, on August 16, for furnishing and erecting a steel structure complete for a straw warehouse at the Desire Street landing. Bids were taken separately for fill, concrete floor, etc., and for the structure above the foundations and for the entire work. Requisition E. D.—13752.

Terminal Enlargement, Norfolk, Va.—The Norfolk City Port Commission has been discussing the necessity for taking up the plans for the construction of the proposed west gallery on the municipal grain elevator, in order to handle the business which is now moving through these terminals. The east gallery is now being built by A. M. Crain & Company, the builders of the elevator. The plans and specifications for the west gallery have been drawn, and the work is estimated to cost in the neighborhood of \$175,000. The commission also has discussed the possibility of being compelled in a short time to erect an additional storage unit of from 500,000 to 1,000,000 bushels capacity.

GOVERNMENT WORK

Dredging, Galveston, Tex. U. S. Engineer, Galveston, plans dredging in Houston Ship Channel. L. M. Adams, district engineer.

Dredges, Louisville, Ky.—U. S. Engineer, P. O. Box 72, will soon take bids for two steel hull dipper dredges 2½ to 4 cubic yards capacity.

Dredging, San Diego, Cal.—Specification 4885. The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans dredging here.

Dredging, Norwalk, Conn.—Sealed proposals were received at the office of the U. S. Engineer, Providence, R. I., on August 22 for dredging in Norwalk Harbor.

Lock Construction, Pittsburgh, Pa.—The U. S. Engineer Office, Pittsburgh, received sealed proposals on August 23 for constructing new Lock No. 7, Monongahela River.

Dredging, Milwaukee, Wis.—Contract for dredging various rivers and channels during the season have been awarded to Great Lakes Dredging & Dock Company, 216 West Water street, \$0.364 per cubic yard, total \$31,500.

Dredging, New York, N. Y.—U. S. Engineer Office, 2nd District, Army Building, awarded the contract for removing St. George Shoal, New York and New Jersey Channels, to G. H. Breyman & Brothers, 17 Battery place, at \$7,200.

Stone Riprap, Harbor Beach, Mich.—Sealed proposals were received at the United States Engineer Office, Detroit, Mich., on August 16 for furnishing and placing, and for recovering and replacing stone riprap at Harbor Beach, Mich.

Dredging, Etc., Buffalo, N. Y.—Bids will be asked for in a short time by the U. S. Engineer Office, Federal Building, Buffalo, for dredging and rock excavation in the Black Rock Canal, Buffalo, approximate cost to be \$250,000.

Pumps, New Orleans, La.—The contract for furnishing two 20-inch dredge pumps to U. S. Engineer Office, 329 Custom House, has been awarded to Ellicott Machine Corporation, Bush and Severn streets, Baltimore, Md. \$11,200.

Tanks, Memphis, Tenn.—U. S. Engineer Office, Mississippi River Dredging District, P. O. Box 1017, awarded the contract for two 20,000-barrel fuel oil tanks, at U. S. Dredge Depot, here, to Walsh & Weldner Boiler Company, Main and Sycamore streets, Chattanooga, \$26,494.

Contract Awarded, Louisville, Ky.—U. S. Engineer Office, P. O. Box 72, awarded the contract for a deep well centrifugal pump, double stroke, 8-inch drop pipe, for Dam 44, to Belknap Hardware & Manufacturing Company, 2nd and Washington streets. \$2,230.

Lumber, Louisville, Ky.—The contract for furnishing yellow pine No. 1 common, 1,300 pieces, 6 by 8 inches by 20 feet; 250 pieces 4 by 6 inches by 20 feet, 120 pieces 2 by 4 inches by 10 feet, etc., to U. S. Engineer Office, Louisville, has been awarded to King Sparrow Lumber Company, Hattiesburg, Miss. \$32 per M feet.

Grain Elevator, Montreal, Que.—Montreal Harbor Commissioners will build Tarte Pier grain elevator by day labor. First unit 2,000,000-bushel capacity reinforced-concrete, structural steel marine towers, track sheds, receiving house and shipping houses, \$2,347,000. J. S. Metcalfe Company, Ltd., 54 St. Francois Xavier street, architects.

Repairs, Philadelphia, Pa.—Sealed proposals were received on August 28 by J. M. Hoffman, Division of Docks and Wharves, Navy Building, Washington, D. C., for repairs to substructure and deck of portions of Piers 97, 98 and 99, Philadelphia Army Supply Base, foot of Oregon avenue, Philadelphia, for the United States Shipping Board.

Steel Booms, Pilcher, Ky.—Sealed proposals were received by the United States Engineer Office, Room 423, Customhouse, Louisville, Ky., on August 27, for furnishing and delivering two steel booms, 67 feet long complete with 22-inch sheaves, etc., delivery to be c/o U. S. Government Engineer, c/o Dam 44, Ohio River, U. S. Siding, Pilcher, Ky., a station on the L. H. and St. L. R. R.

NEW INCORPORATIONS

The Callaghan Transportation Corporation, capital \$100,000, chartered under Delaware laws.

The Bison Steamship Corporation, of Tonawanda, N. Y., capital \$150,000, chartered at Albany. Incorporators: J. J. and M. O'Hagan and J. Gehm.

The Morecraft Transportation Corporation, of Wilmington, Del., capital \$500,000, incorporated under Delaware laws, to engage in the operation of boats.

The Pacific Mail Corporation, capital \$1,000,000, incorporated under Delaware laws. Incorporators: F. M. Stokes, of Woodhaven, L. I.; Joseph F. Mann, of Bloomfield, N. J., and William D. Ahearn, of Brooklyn.

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), National Association of Periodical Publishers, Inc., New York Business Publishers' Association and the Audit Bureau of Circulation (A. B. C.).

Requests for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

A Solution for the Shipping Problem

THE decision of the Attorney General of the United States, regarding the so-called Lasker-Farley plan for the disposition of the Government-owned merchant vessels, has left the Shipping Board once more at sea, exactly where it has been floundering most of the time since Congress refused to pass the ship subsidy bill. Mr. Daugherty's opinion was that the unloading of Government merchant ships on numerous private corporations in which Uncle Sam would be a considerable stockholder and, incidentally the holder of the proverbial bag, would be illegal, consequently, the Lasker-Farley plan has become a dead issue and the Shipping Board must devise some other scheme for solving its vexing problem.

What can be done?

The present method of indirect operation is both unsatisfactory and costly. The loss to the Government is at the rate of \$50,000,000 a year. Moreover, Section I of the Jones Act seems not only to preclude continuous Government ownership but actually to demand that the Shipping Board vessels be sold to private owners.

The approximate value of each and everyone of these vessels is known as a result of the careful and competent survey of all Government-owned merchant ships which has recently been made. Many of the ships are commercially worthless and must therefore be scrapped. There are several responsible concerns, however, which are ready to buy certain ships and routes and, if the Government assumes a business-

like attitude and agrees to terms that are fair to both sides, customers can be found for the others.

To ask a prospective buyer to pay a definite price for an article of questionable value is certainly unfair to the customer and it cannot be denied that some of the steamship routes established by the Government, if not the vessels themselves, are of questionable value. Nor is it right for the Government to turn its property over to private citizens without remuneration and proper protection against loss, but it is conceivable that it would be cheaper in the end to give away as an investment those routes and vessels which are actually of questionable value rather than to continue the present method of Government ownership and semi-Government operation, especially when instances are known where ten ships have been turned over to agents to make possible the continuous operation of five!

The formula that seems to us the solution of the whole problem was given in the editorial "Why Government Ownership?" published on page 387 of our July issue. This reads as follows: "First scrap all ships that cannot possibly be sold because unfit for profitable operation; they are in any event as much of a menace to the progress of the American merchant marine as are derelicts to navigation. Then sell all of the others to private owners either after first installing Diesel engines and in other ways refitting for competitive business such of the vessels as would be amenable to that treatment, or else authorizing the purchaser to do so, the job to be financed by the Government."

To those corporations of American citizens which indicate that they are willing to purchase such vessels or routes, terms of payment that they can meet should be granted. Moreover, the prices charged for the vessels, as well as for the routes, should be in proportion to their respective capital values and their possible earning power. In the event that these values are not known or cannot be determined with any reasonable degree of certainty in advance, an upset minimum based on the worth of the ships alone could be filed, the question of possible additional compensation to be determined after a given period of actual operation on stipulated routes under private ownership.

If this plan were put into effect, the result would be the elimination of a Government expense of at least \$50,000,000 a year and the return to the Treasury of some part of the cost of the ships. At the same time, a new lease of life would be given to the American merchant marine as a whole and a new hope to that great industry which has to do with the building, repairing and equipping of ships.

Revision of Our Maritime Laws Should Be Speeded Up

ONE thorn in the side of the American merchant marine should be speedily removed, and that is the antiquated rules and regulations under which Federal inspection of vessels is conducted. Not only are the present rules and regulations antiquated, but often they are confusing and difficult of uniform and fixed interpretation. Moreover they frequently overlap the rules of the ship classification societies and are at variance with good practice. For some time past a committee acting under Congressional authority and with the co-operation of the Bureau of Navigation and Steamboat Inspection Service of the Department of Commerce has been working on a revision of the maritime laws. Considerable progress has been made and it is believed that the result will correct most if not all of the existing evils. But the matter should not be permitted to lag. American shipowners face too many obstacles to be handicapped at the start by antiquated Government laws and regulations. That the need for prompt action in this matter is acutely felt is shown by the fact that the National Merchant Marine Association has only recently adopted resolutions urging that the recommendations for the revision of the maritime laws be presented to the Congress without delay.

Shipbuilding Prospects

IN spite of the continued depression in the world's shipping there are pending in American shipyards orders for at least thirty-seven new vessels as well as a considerable volume of repair and reconditioning work. While this does not in any way indicate the approach of another shipbuilding boom, it does at least promise some relief for the shipbuilders. Most of the vessels for which bids have been asked are for coastwise or inland waterway service. They include combined passenger and cargo steamships for the Clyde, Southern Pacific, Old Dominion, Oceanic and New York and Porto Rico Lines, a fleet of twenty Diesel electric motorships for lake, canal and coastwise service, cargo ships for special interests and a number of special types of vessels for the inland waterways, including eight ferryboats for the city of New York.

Many of these contracts would probably have been placed weeks ago, if prices had not shown a tendency to stiffen. After a prolonged slack period, however, shipbuilders cannot be expected to take work at ruinous figures and there seems to be no indication of any marked reduction in the cost of shipbuilding materials. As a matter of fact, those who months ago put off the placing of orders for new tonnage in the expectation of securing more favorable prices later on missed a golden opportunity for the day of rock bottom prices seems to have passed and the price of steel apparently is destined to remain far above its level of eighteen months ago.

Meanwhile, certain of the steamship companies need new vessels and it is a question whether any possible saving in initial cost which might be made by waiting for more favorable prices would begin to compensate for the loss of business which might be gained by immediately adding new

tonnage to their fleets. On the other hand, the shipyards are badly in need of new contracts to maintain their skilled forces and it will not be long, if orders are further delayed, before the yards will be far less capable of turning out the work as efficiently and economically as they are today.

Shipyards Committee Appointed

ONE factor which may have a decided influence on the future of American shipbuilding is the work of the shipyards committee recently appointed for the investigation of general conditions affecting shipyards and ship repair plants throughout the country with a view to formulating recommendations for presentation at the forthcoming American Marine Congress in New York city, November 5 to 10. This committee, headed by J. Harry Mull, president of the William Cramp and Sons Ship and Engine Building Company, and including J. G. Pew, president of the Sun Shipbuilding and Dry Dock Company; H. G. Smith, vice-president of the Bethlehem Shipbuilding Corporation; E. P. Morse, president of the Morse Dry Dock and Repair Company, and J. J. Tynan, general manager of the Union Plant of the Bethlehem Shipbuilding Corporation, has already established headquarters in the office of the Atlantic Coast Shipbuilders' Association in Philadelphia and is seeking the co-operation of over two hundred establishments engaged in all branches of shipbuilding and marine repair work. This will give the shipbuilders a chance for co-ordinated action which is bound to reflect favorably on the future welfare of the industry.

Diesel Engines at the Marine Show

THE number of manufacturers and licensees of Diesel engines that are exhibiting at the forthcoming Marine Exposition at the Grand Central Palace, New York, during the week of November 5 to 10 is a significant indication of the belief of a great many shipping experts that this form of propulsion is bound to be the next important development in the establishment of our merchant marine upon an economic basis.

As stated by Professor Chapman in his comparison of steamships and motorships which appeared in the January, 1923, issue of this magazine, if capital is to be interested in shipping ventures it must be shown where it can make a reasonable profit on its investment. Professor Chapman gives this profit at 10 percent which, with the fixed charges of 15 percent for interest, insurance and depreciation, makes a total of 25 percent for the capital charge. Now with the Shipping Board apparently willing to practically give away good vessels providing they are converted to motorships, and with the total estimated cost of these converted vessels at \$50 or less per deadweight ton or about \$20 per ton less than they can be produced in England, it is evident that 25 percent on the difference in capital required to secure a good motorship here as compared with abroad is quite a subsidy in itself.

One thing is certain, and that is that those who have Diesels to sell believe in their future as the space devoted to the internal combustion engine at the Marine Exposition will exceed that given to all other forms of propulsion combined.

What Is the Remedy for the Shipping Situation?

By "Old Scotch"

We are rapidly approaching a showdown in shipping matters in this country. For the past two or three years, since the collapse of the great shipbuilding and shipping boom we have drifted along without a definite policy and without clear-cut leadership. The world trade has declined and freight rates have reached such a low level that the ships now conducting the ocean trade of the world seem only to vie with one another for bare existence without thought of profits to those who have their capital invested in them. We all know that the rehabilitation of normal conditions on the seas is a long time off, and depends upon the stabilization of the former European combatants in the Great War. Our own United States is the only one of the great nations of the earth which has even a semblance of prosperity. While we naturally are deeply interested in all that pertains to general world prosperity, we must consider our own interests of paramount importance; to retain these present fair conditions and to improve them where possible must necessarily receive our first attention.

IT has been conclusively demonstrated to the minds of all thinking Americans that much of the credit for our present comparatively better conditions is due to the fact that we have had sufficient American vessels to regulate freight rates on our exports and to establish and extend our foreign business in new territories. This has, to date, been accomplished principally by the medium of the Government-owned ships in foreign trade, operated by the Shipping Board through the existing system. This system has, owing to the general depression, been operated at a considerable direct loss, chargeable to operation alone. But in the broad view, this extension of the nation's business has resulted in a decided gain to our industries taken as a whole.

THE GOVERNMENT MUST HELP

Two outstanding conclusions may be deduced from our present shipping activities in foreign trade.

1. It is clearly proven from our experience with the operation of Government tonnage that we must have our own ships to conduct at least half of our own foreign trade.

2. To keep sufficient American ships in the foreign trade, to maintain even our present business conditions, and to better them when world trade improves, as they must at some time, the United States Government itself must help either directly or indirectly and perhaps both.

Regardless of the controversy between the Shipping Board and the steamship owners, which is now bringing the subject of Government ownership and operation or private ownership and operation to a crisis, the great object to be obtained is the guarantee to our farmers and merchants that a sufficient amount of American tonnage will be maintained.

LOSSES TO BE REDUCED

Whatever may be the outcome of the dispute between the Shipping Board and the shipowners, it seems to be a settled fact that the present system of operation of Government tonnage is to be replaced by some other method in order to reduce, if possible, the direct financial loss to the National Treasury. This undoubtedly can be accomplished, but just now is the all-absorbing question of the hour.

Direct subsidy in the manner prescribed by the bill which failed of action in the last Congress would undoubtedly have solved the problem, but that now seems to be out of the question for reasons which need not here be discussed.

While it is true that our foreign trade, that is such portion as is being carried under the American flag, is borne in ships directed by the Shipping Board, the future of the American merchant marine in foreign trade is much broader than the mere question of Government or private ownership. The Shipping Board and the Shipowners' Association, while

parties most interested in the present situation, are not alone sufficient to decide on the great shipping question now before the country. The farmers, manufacturers and merchants have the greatest interest in the subject, as the correct solution will largely enter into the question of their success in the future.

MARINE CONGRESS TO POINT THE WAY

Fortunately for all concerned is the fact that the all-American Marine Congress has been called, to meet in New York the first week in November (5th to 10th, inclusive). There will assemble representatives from all branches of industry, directly or indirectly interested in shipping. The proposal for this Congress has been seized upon with the greatest enthusiasm, and representative men will be present from all sections of the country. The farmers will be represented by delegates from the American Farm Bureau, the manufacturers by a number of prominent organizations including the American Manufacturers' Export Association and the United States Chamber of Commerce. All shipbuilding and shipping organizations have appointed delegates, as have various labor associations. Numerous transportation companies, whose interests are closely allied with foreign shipping will through able representatives take part in the discussions. Municipal authorities interested in commerce will be represented to discuss port facilities. The American Legion, the greatest of all our patriotic societies, will have delegates and members present. The marine branches of the Federal Government will each have a representative present to join in the work of the Congress.

With such a galaxy of talent present and sincerely interested in the subject, it is plain to be seen that all phases of the shipping problem can be intelligently discussed by men who can speak.

ENFORCEMENT OF EXISTING LEGISLATION MAY BE URGED

It is difficult even to predict what the recommendations of this gathering will be, but it is safe to assume that intensive consideration will be given to the legislation already on the statute books, which if enforced or invoked will be of great assistance to the maintenance of American ships in the foreign trade. Although former Presidents Wilson and Harding, for reasons which they deemed sufficient, failed to put the policy of discriminating duties in force, it may yet be possible, by certain modifications which may be recommended by the Congress, to convince President Coolidge of the desirability of resorting to that method of encouraging our shipping. Some experts claim that the principle of discriminating trade can be applied advantageously in the indirect trade, such as the Central and South American routes,

without resorting to the abrogation of existing treaties with the great shipowning nations.

The sections of the Jones Act providing for preferential railroad rates on goods carried in American bottoms have not yet been enforced, and give promise of considerable help if properly worked out and applied.

EXTENSION OF COASTWISE LAWS TO THE PHILIPPINES

The inevitable enforcement of the provision relating to placing the Philippines under the coastwise law will be a great boon to American shipping. There now seems but little reason why President Coolidge should delay in making that portion of the Jones Act operative. A good strong resolution from the Marine Congress might have a very beneficial effect towards accomplishing that much desired action.

The increase in freight rates feared by our Philippine brethren (the fear largely inculcated by our shipping rivals in Europe) has been proved to be largely a bugaboo, by comparison with existing freight rates between New York and San Francisco, a distance about the same as from the latter port to Manila. It is estimated that there are 1,272,780 tons of shipping engaged in the Philippine trade. The United States would undoubtedly secure three-fourths of this

Automobile Ferryboat Motor Princess Built for Canadian Pacific Railway

trade for our own ships, if the coastwise laws are made applicable, as now authorized by law.

As before stated, the Government must help to retain the American flag in foreign trade, and the Marine Congress will inevitably devote much of its time to discussing and recommending ways by which this Governmental help can be efficiently applied without too much drain on the Treasury.

UTILIZATION OF NAVAL FORCES ON MERCHANT VESSELS

It has been suggested that the wage differential, now the most serious handicap on American ships in world wide competition, may be overcome by utilizing enlisted men from the authorized personnel of the Navy on ships engaged in the foreign trade. Despite the opinion of strictly militarists, it is very apparent that the impoverished nations of the world will not be able to engage in any great conflicts on the sea for some years yet to come. While we all believe in preparedness, there is no particular use in over preparedness, and we must use good sane judgment in appraising conditions which can arise. The utilization of naval forces on merchant vessels would in no way detract from their readiness to meet any emergencies which might arise, and at the same time they may be extremely useful in helping to solve our merchant marine problem.

These and other phases of the problem will most likely receive attention at the forthcoming marine gathering, and it is but fair to presume that the recommendations made will be based on the good sound judgment of all interested parties.

SHIPPING BOARD SHOULD POSTPONE ACTION

In view of the near approach of this all-American Marine Congress, of the great diversity of the interests represented, and of the intelligent discussion which will ensue, does it not appear that it would be fitting for the Shipping Board to postpone any definite policy regarding the method of using its ships, until they can have the benefit of the recommendations made by this nation-wide council?

New Motor Ferryboat Has Capacity for Fifty Cars

THE new *Motor Princess*, built by the Canadian Pacific Railway, is said to be the first specially built automobile ferryboat in the world, and a new floating link in the chain of friendship binding the United States and Canada together. Motorists board her, 250 strong and 50

600 Horsepower McIntosh & Seymour Diesel Engines of the Motor Princess

cars at a time, at Bellingham, Wash., cross the Gulf of Georgia to Sidney, Vancouver Island, run their cars off the boat and tour over automobile roads to Victoria and Nanaimo, or farther north.

The *Motor Princess* is a staunch craft 170 feet long and 42 feet wide, with decks 11 feet high. She is driven at a speed of 14 knots by two 600 horsepower McIntosh & Sey-

Main Parking Deck Looking Forward to Ramp Leading to Upper Parking Deck

mour Diesel engines, and there are ample observation and smoking rooms, as well as a ball room and tea room, for the comfort of passengers during the three hours' trip between the States and Canada. Last year 18,000 automobiles were carried on the *Princess* steamers from Seattle to Victoria and Vancouver, and now that the *Motor Princess* is at their service it is expected that even more will visit Vancouver Island and the British Columbia mainland.

Shipping Board Plan Held Illegal

Attorney General Advises President Shipping Board Lacks Authority to Carry Out Proposed Plan

By Harold F. Lane

WASHINGTON, D. C.

ATTORNEY General Daugherty on September 19 threw a large monkey-wrench into the plans of the Shipping Board for operation of the Government fleet through 12 to 18 subsidiary corporations of the Emergency Fleet Corporation, whose stock was to be owned by the Shipping Board, by giving President Coolidge an opinion, at his request, that the so-called Farley-Lasker plan, suggested by the policy committee of the board as a substitute for the present plan of operating through managing agents, is illegal. The result is expected to be that the whole question of Shipping Board policy will again be thrown before Congress at the coming session.

RESULT NOT UNEXPECTED

Such an opinion from the attorney general was not exactly unexpected, as it is in line with the opinions of three of the seven members of the Shipping Board who had voted against the adoption of the subsidiary plan, as well as of many others outside the board, although counsel for the board had declared the plan legal, and President Coolidge had previously let it be known that, even if the plan were held legal, he proposed to have a further study made of the advisability and wisdom of the policy, by the special committee which he had suggested.

The President regards it as fundamental, it was said at the White House, that any plan of operation must be such as will assure adequate shipping facilities for the commerce of the country and at the same time provide a merchant marine auxiliary to the Navy for the national defense.

It was also stated officially after the President had received the opinion of the attorney general that he had no new policy to suggest and that it is not the business of the President under the law to try to formulate policies for the Shipping Board, although he would be glad to and expected to confer shortly with the members of the board as to some plan for trying to get the ships into private hands as soon as possible. It was added that the plan had appealed to him as probably the best step toward liquidation and private operation that could be taken at this time but that since it has been decided impossible to make it effective under the present statute he did not know what would be done or whether the board would desire legislation.

ALTERNATIVES AVAILABLE

The alternatives left to the board now apparently are to try to work out further economies under the present plan; to adopt for the entire fleet a plan similar to that under which the United States Lines operate, with a salaried manager employed directly by the Government, or to ask for some modification of the law.

Attorney General Daugherty advised the President that the Government does not possess the power under the Merchant Marine Act to carry out the proposed plan of the Shipping Board to dispose of Government-owned ships through the incorporation under state laws of corporations authorized to own and operate such craft. He was of the opinion, he added, that the statute authorizes a sale of the ships and not an exchange of title thereto in consideration of stock in a corporation, which the proposed plan of the Shipping Board contemplated when the matter was placed before President Coolidge for consideration.

It evidently was the intention of Congress, Mr. Daugherty said in his opinion, to authorize a sale for cash or on credits not to exceed 15 years from the making of the contract of sale, and that an exchange whereby the Government receives shares of stock in return for its ships is not a sale within the provision of the act and does not meet the condition limiting deferred payment. Moreover, if the transfer of vessels to state corporations in return for the issuance of capital stock is to be regarded as a passing of title authorized by the sale provisions of the act, the attorney general added, "it is obvious that Section 14 of the act must be ignored, for its provisions, as we have seen, contemplate the payment of money and not shares of stock into the Treasury of the United States as miscellaneous receipts."

If any weight is to be given to the long settled legal principle that a corporation is a distinct juristic person, holding its property and exercising its corporate function through the appointed agents, Mr. Daugherty said, "it must be admitted that under the present proposal the Government will in a real and substantial sense part with title to its vessels."

GOVERNMENT NOT AUTHORIZED TO TRANSFER SHIPS

Serious questions likely would arise as a consequence of the assumption by the Government of the ownership of stock in a private corporation controlled by state law, the attorney general pointed out, as it possibly would be contended that under statutes imposing assessments to meet the debts of the corporation the Government would be liable as any other stockholder. The vessels transferred to the corporation, he added, might even become legally subject to state taxation, and such immunity from suit as the Government now enjoys with respect to the operation of its fleet would very likely disappear. Undoubtedly, also, the attorney general further explained, the directors and officials of the proposed corporations would not be officers of the United States, and thus the United States in the administration and operation of its shipping industry would lose (except under statutes like that under consideration in United States vs. Bowman, 206 U. S. 94) the benefits of the sanctions provided by law to secure the good conduct and public accountability of its agents.

These considerations, Mr. Daugherty said, impelled him to the opinion that it was not the intention of Congress to authorize the executive branch of the Government to organize corporations to take title to the Government's ships, and in the place of responsible Government control by the Shipping Board substitute a management by directors of private corporations amenable alone to the laws of another sovereignty. There have been instances of the formation of corporations to aid in the discharge of administrative function the attorney general explained, adding that, however, in each case, so far as he was aware, there had been unmistakable legislative authority. There is no language of like import in the statute now under consideration, Mr. Daugherty declared, and he concluded that, "the authority to transfer the ships to private corporations can not fairly be rested on the provisions in the act relating to sales."

Is it possible to construe the provisions relating to the maintenance and operation of the fleet as permitting, as a method of operation, the proposed transfer? Mr. Daugherty asks, and proceeds to answer the question by quoting sections

7 and 12, of the act, which relate to the establishment and operation of steamship lines, reconditioning, etc., asserting that there is no further provision, than is found in the two sections quoted, for the delegation of the authority confided by the statute in the officials of the Shipping Board.

"It is a well settled rule," Mr. Daugherty said, "that a public officer or public body can not delegate powers which require the exercise of judgment or discretion. . . . The operation and maintenance of the fleet until sold was entrusted by Congress to public officials who are at all times subject to congressional control. It cannot be admitted that this important trust can be put in the hands of the directors of a private corporation who bear no official relation to the Government; who are merely the trustees of the corporation and removable as such only through the processes of corporate management prescribed by the various and varying systems of state law.

"Moreover," continued Mr. Daugherty, "if the proposed plan is to be regarded not as a sale, but merely as a method of operation, it does not conform to the program set forth in section 12 (of the act). This section contemplates that operation shall continue only until the vessels are sold. *And yet under the plan it is made impossible to sell the ships hereafter for the reason that the Government will have placed the legal title to them in the proposed corporation and will have nothing to sell except the stock which it has received in exchange.*"

Mr. Daugherty called attention to the fact that when the bill for a merchant marine act was introduced in the House it contained a provision which stated that the power and authority vested in the board might be exercised directly by the Shipping Board, or by it through the United States Emergency Fleet Corporation or other agencies created pursuant to authority of law. The underscored words were stricken out in the Senate, and the House agreed to the amendment. This circumstance, Mr. Daugherty said, was significant, and it "negatives the idea that Congress intended that the power and authority vested in the board should be exercised by any one outside the board itself or the Emergency Fleet Corporation."

BOARD CANNOT MAKE RULES TO COVER PLAN

In connection with the suggestion that the power of the Shipping Board under the law to make rules and regulations might be broad enough to authorize the board to put into execution the plan proposed, Mr. Daugherty states that Section 19 of the act directs the board to aid in the accomplishment of the purposes of the act to make all necessary rules and regulations to carry out its provisions . . . "rules and regulations which are not inconsistent with the act or which are not unreasonable or inappropriate."

But rules and regulations not authorized by the statute, the attorney general held, would be invalid, and the authority to promulgate rules and regulations "can, therefore, add nothing substantial to the powers conferred."

Finally, Mr. Daugherty says, the question is presented whether the language of section 1 confers the power proposed to be exercised.

"That section, as we have seen," the attorney general advises, "announces a national policy. After declaring that for the national defense and for the growth of commerce it is necessary that the United States should have a merchant marine ultimately to be owned and operated privately by its citizens, the section provides . . . 'it is hereby declared to be the policy of the United States to do whatever may be necessary to develop and encourage the maintenance of such a merchant marine, and, in so far as may not be inconsistent with the express provisions of this act, the United States Shipping Board shall, in the disposition of vessels and shipping property as hereinafter provided, in the making of rules and regulations, and in the administration of the shipping

laws keep always in view this purpose and object as the primary end to be attained.'

"But this adds nothing to the power conferred. The language is that in the disposition of the vessels and shipping property 'as hereinafter provided' this end shall always be kept in view. The authority to sell and until sold to operate the Government vessels was conferred in subsequent sections; and, within the scope of the powers given, the board is directed to keep in view the policy and purpose thus announced. Although the title or preamble of an act may be referred to when ascertaining the meaning of a statute which is susceptible of different constructions, they cannot control or restrain express provisions. . . . Nor can they enlarge or confer powers. . . . I accordingly have the honor to advise you that in my opinion the power to carry out the proposed plan does not exist."

President Coolidge has devoted very close study during recent weeks to the situation of the Shipping Board and its proposed plan and several times had called upon the board for further details and estimates as to how much it would cost and what savings could be effected as compared with the present plan. He had also called the entire membership of the board into conference with him at the White House on the evening of August 30, at which he is said to have been a "good listener." It was after this conference that the attorney general was asked for a formal opinion, although it is understood that the board had previously received informal assurances that its plan would not be in violation of the existing law.

CONFERENCE WITH SHIP OWNERS AND OPERATORS

There was practically nothing in the way of definite results from the all-day conference held between the board and committees representing the steamship operators and owners at Washington on August 28, at which the latter were given an opportunity to submit alternative plans. A new plan as a substitute for the present managing operator contract was proposed by C. H. Potter on behalf of the United States Ship Operators' Association, the purpose of which was to put on the operator or agent a greater measure of responsibility than at present, so that, if the present losses increase, the agent would bear a substantial share of such increase, whereas, if they diminish, he would receive some of the resulting benefit. It was proposed to set up an agreed standard figure for each trade route to represent the net result per voyage and that, if the agent should do no better than this standard, he would receive no compensation for operation but only a husbanding fee. If his operation should show a surplus above the standard figure, it would be divided on an agreed percentage basis between the board and the operator and a certain percentage of the amount received by the board was to go into a purchase and building fund which might be applied on the purchase of ships by the operator.

Gale H. Carter, vice-president of the American Steamship Operators' Association, also presented a statement of arguments against any plan of Government operation with a suggestion that the board and the shipping men endeavor by co-operation to work out a "plan by which the Government ships can be most efficiently and economically operated by private parties and ultimately transferred to private ownership," and "the board gradually retired from the shipping business."

Chairman Farley, however, gave no indications of having been at all impressed with the alternative suggestions presented by the shipping men and said that, if anything were to be accomplished, the board must have more concrete and specific proposals and without delay. The conference was adjourned with the idea that the shipping men might get together and formulate a more definite plan for the consideration of the board later, if they could do so within very short time.

Secretary Hoover to Preside as Chairman of the Marine Congress During American Marine Week

Greatest Convention Ever Held of Commercial, Manufacturing, Farming and Maritime Associations to Discuss Merchant Marine Problems During Week of November 5 to 10

THE eyes of the nation will be focussed on New York during the week of November 5 to 10, for in the space of six short days technical and practical shipping questions and the exhibits at the great annual Marine Exposition will be given the widest publicity. The fact that organizations in such cities as Omaha, Duluth, Cincinnati and many other interior points are going to the expense of sending delegates to this Congress shows that the country at last has awakened to the necessity of an American merchant marine.

The writer attended a farmers' conference in Cincinnati on the merchant marine in June and he was greatly surprised and pleased to see the enthusiasm displayed by the delegates on shipping matters. They have come to realize that their prosperity depends on economical and efficient transportation of their products and with that realization has come the determination to find a solution that will induce private capital to invest in shipping.

There are four major groups of our industries, namely: Agriculture, mining, manufacturing and transportation. The first three have been developed far beyond the actual needs of the country and now agriculture in particular is severely suffering because we have, in our laws and our regulations, handicapped our transportation facilities. In fact, our merchant marine is now threatened with the evil of direct Government operation which the former chairman of the Shipping Board, Albert D. Lasker, once characterized as "poison ivy in the garden of industry."

It is useless to harp on what might have been done if the subsidy bill had been passed. We are faced with the problem of making a new start but with the facts and findings arrived at by a non-partisan body—and our merchant marine question is just as non-partisan as our army or navy—representing all sections of the country, we will have something to build on that Congress will not dare to ignore.

This Congress, as we have said in our title, will be presided over by Secretary Hoover whose reputation for efficiency in organization and for getting results is international.

Announcement of the personnel of the Great Lakes District Committee; a special technical committee to represent the shipowners of the Great Lakes; a committee representing the agricultural interests of the Mid-West, and the Marine Insurance and Classification Committee, in connection with the Congress is the latest word from the headquarters of the American Marine Association, at whose invitation the Congress will be held. Inasmuch as the chief executives of four cities are listed as members of the Great Lakes Committee, much is expected of the group whose personnel is the more interesting when it is remembered that the mayors of six cities have already consented to serve on the Delaware District Committee.

The make-up of the Great Lakes District Committee, which will represent the regional interests of all of the Great Lakes States and which is now complete, is as follows:

Chairman, F. C. Bradbury, manager of the Marine Department of the Crane Company, Chicago, Ill.
Honorary Chairman, Hon. William E. Dever, Mayor of Chicago, Ill.
Hon. George E. Leach, Mayor of Minneapolis, Minn.
Hon. Fred Kohler, Mayor of Cleveland, Ohio.
Hon. Judge B. F. Brough, Mayor of Toledo, Ohio.

William M. Pattison, president, The W. M. Pattison Supply Company, Cleveland, Ohio.

R. E. Sawhill, editor, *Marine Review*, Cleveland, Ohio.

Harold Emmons, president, Detroit Board of Commerce, Detroit, Mich.

C. E. Boyd, assistant secretary, Detroit Board of Commerce, Detroit, Mich.

A. A. Schantz, president, Detroit & Cleveland Navigation Company, Detroit, Mich.

W. W. Nichols, vice president, Society of Industrial Engineers, Detroit, Mich.

Robert June, Diamond Power Specialty Company, Detroit, Mich.

A. M. Creed, Creed & Company, Detroit, Mich.

John Cowell, president, Board of Trade, Toledo, Ohio.

P. R. Merk, Board of Trade, Duluth, Minn.

Walter J. Fitzgerald, Lake Transportation & General Insurance, Milwaukee, Wis.

Harwood Frost, Terminal Engineer, Chicago, Ill.

F. E. Heath, Association of Commerce, Grand Rapids, Mich.

A special Technical Committee, which will represent the Great Lakes Ship Owners, is making rapid strides in the formulation of a policy which is expected to tie together the shipping men of the Great Lakes and the shipping men of the coast. This committee is as follows:

Chairman A. A. Schantz, president, Detroit & Cleveland Navigation Company, Detroit, Mich.

C. F. Bielman, secretary and general manager, White Star Lines.

Oliver S. Dustin, vice president, Ashley & Dustin.

P. G. Findlay, traffic manager, Dodge Bros. Auto Company.

Henry T. Ewald, president, Ewald Advertising Agency.

A powerful group under the leadership of George A. Carey, secretary of the Omaha Chamber of Commerce, will represent the agricultural interests of the Mid-West and is in itself a notable committee. It is made up as follows:

Chairman, George M. Carey, secretary of the Omaha Chamber of Commerce.

Carl H. Gray, president, Union Pacific Railroad, Omaha, Neb.

Henry W. Meile, vice president, Merchants National Bank of Omaha, Nebr.

H. D. Lute, secretary of Nebraska Farmers Bureau Association, Lincoln, Nebr.

Joseph F. Leopold, general secretary, Iowa State Chamber of Commerce, Des Moines, Iowa.

James F. Coupe, assistant secretary, Iowa Farm Bureau Association, Des Moines, Iowa.

Harry L. Keefe, president, Nebraska Farm Bureau Association, Walthill, Nebr.

Additional committee personnel is announced with the naming of the Marine Insurance and Classification Committee, which is made up as follows:

Chairman, S. D. McComb, manager, Marine Office of America, New York City.

Captain C. A. McAllister, vice president of the American Bureau of Shipping, New York.

Charles D. Mather, Philadelphia.

Frank Gair Macomber, Boston, Mass.

James A. Mathews, San Francisco, Cal.

The latest word received on committee-chairmanship acceptances is that R. S. MacElwee, commissioner of the Port of Charleston, S. C., has agreed to serve as head of the Southern States District Committee.

With regard to the Marine Show, the list of exhibitors is growing steadily, one of the latest additions being the port of Charleston, S. C.

The following is a list of exhibitors who have already

reserved space for the 1923 exposition, together with their booth numbers:

	Booth No.
Ajax Rope Company, Inc., 149 Broadway, New York.	44
Akimoff Propeller Company, Harrison Building, Philadelphia, Pa.	67-B
American Car & Foundry Company, 165 Broadway, New York	85 (part)
American Krupp System Diesel Engine Company, 165 Broadway, New York.....	80
American Society of Marine Designers, 29 West 39th Street, New York.....	294 and 295
American Steel Foundries, Chicago, Ill.....	52
Asbestolith Manufacturing Company, 1 Madison avenue, New York	97
Ashton Valve Company, 161-179 First Street, Cambridge 41, Boston, Mass.....	(part of) 18 and 19
Babcock & Wilcox Company, 85 Liberty Street, New York	76-77
Beaver Tile, Inc., 442 West 42nd Street, New York...	11
Bethlehem Shipbuilding Corporation, Ltd., Bethlehem, Pa.	68
Briggs Engineering Works, 227 24th Street, Brooklyn, N. Y.	104
Brown Instrument Company, 50 Church Street, New York	65-B
Burmeister & Wain, Ltd., 27 Whitehall Street, New York	86
The Coen Company, 50 Church Street, New York....	79
Wm. Cramp & Sons Ship & Engine Bldg. Company, Philadelphia, Pa.	70-71
Crane Company, 836 South Michigan Avenue, Chicago, Ill.	66
Crane Packing Company, 59 Park Place, New York...	227
Diamond Power Specialty Corporation, Detroit, Mich..	74
O. M. Edwards Company, Inc., Syracuse, N. Y.....	15
Electric Storage Battery Company, 26 West Broadway, New York	31
Electro Sun Company, Inc., 161 Washington Street, New York	253
L. W. Ferdinand Company, 152 Kneeland Street, Boston, Mass.	228
Fire Detecting Wire Corporation, 2 West 45th Street, New York	335-336
Foster Marine Boiler Corporation, 111 Broadway, New York	101
General Carbonic Company, 542 Fifth Avenue, New York	49
General Electric Company, Schenectady, N. Y.....	3-4-5-6
B. F. Goodrich Rubber Company, Akron, O.	84 (half)
Griscom-Russell Company, 90 West Street, New York.	60
Hill Rotors, Inc., 42 Broadway, New York.....	252
Hooven-Owens-Rentschler Company, Hamilton, Ohio..	17
Journal of Commerce and Commercial Bulletin, 32 Broadway, New York	50
Walter Kidde & Company, 140 Cedar Street, New York	49
Knudsen Motor Corporation, 30 Church Street, New York	81
London Steam Turbine Company, 149 Broadway, New York	29
Lunkenheimer Company, Cincinnati, O.....	95
McIntosh & Seymour Corporation, Auburn, N. Y.....	59
Mack Engineering & Supply Company, Inc., 136 Liberty Street, New York.....	348
Marine Decking & Supply Company, 116 North Delaware Avenue, Philadelphia, Pa.....	110
MARINE ENGINEERING AND SHIPPING AGE, 30 Church Street, New York.....	94-106
The Marine News, 26 Water Street, New York.....	83
The Marine Review, Cleveland, O.....	30
Morse Dry Dock & Repair Company, foot 56th Street, Brooklyn, N. Y.	72
National Malleable Castings Company, Cleveland, O...	57
National Meter Company, 229 Broadway, New York...	14
Natural Carbonic Gas Company, Newark, N. J.....	267
Newport News Shipbuilding & Dry Dock Company, Newport News, Va.	32
Northern Fire Apparatus Company, Minneapolis, Minn.	54
Pantasote Company, 11 Broadway, New York.....	28
Peabody Engineering Corporation, 110 East 42nd Street, New York	13

	Booth No.
Pneumercator Company, 40 Flatbush Avenue, Brooklyn, N. Y.	36
Port of Charleston, Charleston, S. C.	255
Power Specialty Company, 11 Broadway, New York...	101
Radio Corporation of America, New York	48
The Roto Company, Hartford, Conn.....	266
Row & Davis Engineers, Inc., 90 West Street, New York	63
R. S. V. Valve Corporation, New York	51
Rubber-All-Products Company, 821 Broadway, New York	69
Scovill Manufacturing Company, Waterbury, Conn....	58
Shipley Construction and Supply Company, 42nd Street and 2nd Avenue, Brooklyn, N. Y.....	33
Sperry Gyroscope Company, Manhattan Bridge Plaza, Brooklyn, N. Y.....	20-21-22-23
The Sterling-Cooper Corporation, 220 West 42nd Street, New York	67-A
B. F. Sturtevant Company, Hyde Park, Boston, Mass.	107
Submarine Signal Company, Boston 9, Mass.....	256
Sun Shipbuilding Company, Chester, Pa.....	78
The Superheater Company, 17 East 42nd Street, New York	73
The Texas Company, 17 Battery Place, New York....	35
W. & J. Tiebout Company, 118 Chambers Street, New York	27
P. S. Thorsen & Company, Inc., 82 Coffee Street, Brooklyn, N. Y.....	98
Valentine & Company, 456 Fourth Avenue, New York.	43
Westinghouse Electric & Manufacturing Company, 165 Broadway, New York.....	82-83
C. H. Wheeler Manufacturing Company, Lehigh and Sedgley Avenues, Philadelphia, Pa.....	7
Worthington Pump & Machinery Corporation, 115 Broadway, New York.....	96

Naval Architects and Marine Engineers to Hold Annual Meeting in New York on November 8 and 9

THE thirty-first general meeting of The Society of Naval Architects and Marine Engineers will be held in the Engineering Societies Building, 29 West 39th Street, New York City, Thursday and Friday, November 8 and 9. Professional sessions will begin at 10 A. M. each day.

The following papers will be read and discussed at the professional sessions:

THURSDAY, NOVEMBER 8

- "Additional Notes on American Shipyard Apprenticeships, Evening Schools and Scholarships." By Charles F. Bailey, member of council.
- "Comments on Aviation, Naval and Commercial." By Captain Emory S. Land, CC. U. S. N., member.
- "Some Factors Affecting the Economy of Operation of the Lake Freighters." By Professor Anders Linblad, member.
- "Wetted Surface." By Henry H. Schulze, member.
- "Propeller Design Based Upon Model Propeller Experiments." By Rear Admiral David W. Taylor, CC. U. S. N., (Retired), honorary vice-president.

FRIDAY, NOVEMBER 9

- "The Probable Effect Upon Ports of the Probable Growth of Ships." By Commander John H. Walsh, CC. U. S. N., (Retired), member.
- "The Economics of Trans-Atlantic Liners of Various Lengths." By Carl E. Peterson, member.
- "The Manufacture of Heavy Steel Castings for Ships with Special Reference to Stern Frames, Rudders, Shaft Brackets and Stems." By Hugo P. Frear, member of council.
- "Fuel Conservation and Engineering Performance Standards by Shipping Board Vessels." By Joseph E. Sheedy, member.
- "Some Considerations on the Conversion of Steamships to Motorships." By Robert Haig, member of council.

The annual banquet will be held in the Grand Ball Room of the Waldorf-Astoria Hotel, New York City, on Friday evening, November 9, at 7:30 P. M. Immediately preceding the banquet there will be a reception beginning at 7:00 P. M.

What Shall Be Done with the Ex-German Transatlantic Passenger Liners *Agamemnon* and *Mount Vernon*?

Conversion to 18-Knot Oil Burners Would Cost Only \$3,000,000 Each and Would Provide Excellent Running Mates of the *George Washington* for Next Year's Passenger Business

[Contributed]

THE twin screw steamships *Agamemnon* and *Mount Vernon*, formerly known as the *Kaiser Wilhelm II* and *Kronprinzessin Cecilie* respectively, were prior to the war familiar to the transatlantic traveling public as the crack ships of the North German Lloyd Line. Both are now lying in idleness, one at Boston, Mass., and the other at Brooklyn, N. Y., and because of the vicissitudes of the United States Shipping Board and Emergency Fleet Corporation are apparently destined to remain in idleness. It is apropos to present a brief review of the histories of these vessels leading up to the events which now find them, splendid as well as profitable in their day of passenger service, inactive rather than as a valuable part of the United States Lines' fleet.

The *Agamemnon* was built by the Vulcan Works, Stettin, Germany, in 1902, and was first placed in service in the early part of 1903. We are told that after but one year on the Atlantic run the financial results and the fine performances of the vessel in other respects were so gratifying that the North German Lloyd immediately placed an order with the same shipbuilding firm for a similar vessel. The keel for the second vessel, the *Mount Vernon*, was laid in 1905. The vessel was launched in 1906 and placed in service alongside of the *Agamemnon* in the latter half of 1907. Both vessels continued in this service, proving veritable gold mines for their owners, until the beginning of the war brought their careers as a part of Germany's merchant marine to a close.

VESSELS SHOULD BE CREDITED WITH A HANDSOME BALANCE FOR TRANSPORT SERVICE

The entry of the United States into the war brought with it the seizure of both vessels which were subsequently overhauled and fitted out as troop transports. The service these vessels rendered in this respect is too well known for further comment but it may be mentioned that if the vessels were credited with the number of troops carried at the standard troop transportation rate then prevailing we may be assured that the vessels would show a very considerable balance in their favor quite apart from the other services.

The *Agamemnon* was put out of commission as a transport and turned over to the Shipping Board on November 22, 1919, and on the 24th plans and specifications for her reconditioning commenced, the services of Messrs. Kindlund and Drake, naval architects, being engaged for the purpose of making a survey and preparing plans showing the vessel in its present condition. On March 24, 1920, the vessel was sent to the New York Navy Yard where the engines, boilers and auxiliary machinery were thoroughly overhauled, new lifeboats and mechanical davits fitted and other repairs

made to the extent of an approximate expenditure of \$2,056,000. The *Mount Vernon* was put out of commission as a transport, turned over to the Shipping Board and placed in the Boston Navy Yard to have similar work carried out to the extent of an expenditure of approximately \$625,000.

POTENTIAL VALUE OF THE VESSELS RECOGNIZED

The International Mercantile Marine Company, knowing these vessels' age and condition, in their bid for the purchase of the ex-German passenger vessels dated January 17, 1920, included one or both in the three proposals submitted showing that a reputable and responsible concern was keen to realize the potential value of a fleet including the *Agamemnon* and *Mount Vernon*.

On May 28, 1920, a contract was entered into between the Shipping Board and the United States Mail Steamship Company whereby that company would acquire a number of the ex-German vessels, arrange for their reconditioning and place them in the transatlantic service; included among these were the *Agamemnon* and *Mount Vernon*. Coincident with the work which was being carried out by the Navy Yards a complete study was made by the United States Mail Steamship Company's technical staff. Plans and specifications for reconditioning the vessels were prepared for restoring in general their original arrangements having in view the appointments desired by the American ocean traveler rather than that of the heavy Continental character which previously obtained. An alternative arrangement was prepared for converting the vessel to burn oil instead of coal for fuel. By August, 1921, this work had progressed almost to the point of obtaining firm bids from the various shipyards when the company, being out of harmony with the board and unable to finance its undertaking, was forced into bankruptcy and the reconditioning of the vessels was suspended.

UNITED STATES LINES FAVORED RECONDITIONING THE VESSELS

The United States Lines succeeded the United States Mail Steamship Company in the operation of the Shipping Board's transatlantic fleet of passenger vessels. It was not long before it became apparent that it was desirable to augment this fleet with vessels having more speed, greater tonnage and finer appointments than the majority of its vessels then offered; and again the *Agamemnon* and *Mount Vernon*, potential high grade liners, were looked to as being the only suitable vessels which could be placed in service within a reasonable time.

It will be recalled that careful studies of probable revenues and expenditures were made and in one instance published.

Fig. 1.—Sketch Showing How the *Agamemnon* and *Mount Vernon* Would Look if Converted to 18-Knot Oil Burners

(See MARINE ENGINEERING AND SHIPPING AGE, January, 1922). All of these were favorable to the reconditioning of the vessels. Later, at the time the Shipping Board was considering the authorization for proceeding with the actual reconditioning of the *Leviathan*, Mr. T. H. Rossbottom, general manager of the United States Lines, was extensively quoted in the press as saying that, if he were given the choice between the *Leviathan* and the *Agamemnon* and *Mount Vernon*, he would choose the latter two, thus indicating the desirability from an operator's viewpoint of having these two vessels in service. It might also be mentioned here that Mr. Rossbottom in his testimony on April 11, 1922, at the joint hearings before the committee on commerce of the United States Senate and the committee on the merchant marine and fisheries of the House of Representatives, said that, if he had the *Mount Vernon* and *Agamemnon* in the North Atlantic service, those vessels could make money in either Government or private operation.

Upon Shipping Board Commissioner Frederick I. Thompson's return from Europe on September 15, 1922, the question of reconditioning these vessels was again brought forward by his advocacy of placing them in service in view of the demand for accommodations on the United States Lines' vessels. Nothing further was done until November 17, when an inspection was made of the *Agamemnon* then lying at Hoboken, N. J. This inspection party was headed by Commissioner M. Lissner and was composed of Messrs. W. J. Love and Joseph Sheedy, vice-presidents; Mr. John Bailey, assistant manager of repairs; Col. R. M. Watkins, operating manager, all of the Emergency Fleet Corporation; Mr. W. F. Gibbs, of Gibbs Brothers, Inc., Mr. Carl E. Petersen and Mr. Wm. L. Bunker, naval architect and superintendent engineer, respectively, of the United States Lines. The excellent condition of the vessel together with its suitability after reconditioning for the passenger service so favorably impressed the Shipping Board officials they decided to direct that a survey be made of both the *Agamemnon* and the *Mount Vernon*.

BOARD OF SURVEY APPOINTED

On December 13, 1922, it was announced that the Board of Survey which was to examine the vessels with a view to making recommendations for their future use had been formed. The members of this board were: Mr. W. F. Gibbs, of Gibbs Brothers, Inc., chairman; Mr. Joseph W. Powell, former president of the Emergency Fleet Corporation; Mr. C. F. Bailey, chief engineer of the Newport News Shipbuilding and Dry Dock Company; Captain C. A. McAllister, vice-president of the American Bureau of Shipping, and Mr. Harry Brown, formerly of the Bethlehem Shipbuilding Corporation.

It will be recalled Mr. Powell had, after having retired from the Emergency Fleet Corporation some time previous to this, surveyed these vessels and submitted an estimate of reconditioning costs to Chairman Lasker. Mr. Powell's exact figures were not given out but it is understood that it was estimated that between \$5,000,000 and \$6,000,000 for both would be required to put them in service as three-class ships but as coal burners. Conversion to oil would require about \$450,000 additional outlay per ship.

The Board of Survey proceeded to make a thorough inspection and detailed study of these vessels and their findings and recommendations confirmed all that had previously been stated relative to the condition of the vessels and their suitability for active passenger service. This board estimated that the cost of changing the fueling system from coal to oil and refitting the liners as modern three-class steamers would be from \$4,000,000 to \$4,500,000 each. The Shipping Board at a meeting on March 14, 1923, instructed Messrs. Gibbs Brothers, Inc., to proceed to draw up plans and specifications so that these could be sent to prospective bidders the first week in June.

An idea of the extensive work called for by these plans and specifications can best be realized by the fact that in the latter part of May the Shipping Board was advised that the cost of carrying out the work specified would certainly exceed \$8,000,000 for each vessel whereupon the Shipping Board abandoned the project as proposed and passed a resolution to ask the next Congress to appropriate \$24,000,000 to build two new ships.

SHALL THE VESSELS BE SCRAPPED?

To anyone who has had the opportunity to inspect or carefully survey these vessels he would undoubtedly answer NO to any suggestion of scrapping. The machinery, main engines, boilers and auxiliaries as well as the hulls proper are in a wonderfully well preserved condition; the accommodations in general and the various systems only being in such bad condition as to necessitate complete renewal. The necessity to balance our merchant fleet with vessels of this class together with the fact that these particular ones, so far as the essential vitals are concerned, are suitable for service should preclude serious consideration being given to the suggestion to scrap them.

SHALL THEY BE SOLD?

The market at this time for the sale of these vessels is primarily a foreign one. If sold abroad, they would undoubtedly go to German interests who would recondition and place them in direct competition with the United States Lines. In fact, a high official of the North German Lloyd Line has stated that apart from the great differential in reconditioning and operating costs here and abroad that company would, if given the opportunity, waste no time in getting the vessels into active service. For proof of this the reader is referred to what occurred to the S.S. *Pocahontas*, now known as the S.S. *Bremen*.

SHALL THEY REMAIN INACTIVE?

It is well known that a vessel in lay-up in spite of extreme care depreciates much more rapidly than when in service. The *Agamemnon* and *Mount Vernon* have been excellently cared for in lay-up until some time ago when the personnel aboard them was very materially reduced as a measure of payroll economy. For reasons of offsetting rapid depreciation and eliminating lay-up costs the vessels should not be continued in their present state.

SHOULD THEY BE RECONDITIONED?

The proposal implied by the Shipping Board's resolution to ask Congress to appropriate funds for the building of two vessels to be used in lieu of the *Agamemnon* and *Mount Vernon* would be a very creditable one from the viewpoint of having thoroughly American vessels of more modern proportions and construction were it a certainty that Congress would make this appropriation. If the attitude of Congress toward the merchant marine is properly sensed, there appears to be very little likelihood of its voting funds for additional governmental construction.

Prior to the Shipping Board's resolution an anonymous argument against the reconditioning of the *Agamemnon* and *Mount Vernon* in favor of the building of new vessels was made by a private owner who evidently was not familiar with the provision of the Jones Act prohibiting the board from constructing new vessels from their funds. This same act makes provision for a construction fund from which private American owners contemplating building new vessels can obtain loans at a reasonable interest rate to enable them to finance their projects and to promote construction. It is worthy of note that up to date no owner has made application for moneys from this fund to build vessels of the type under discussion whereas many vessels have been reconditioned.

Now then, if the *Agamemnon* and *Mount Vernon* should

neither be scrapped, sold nor continued in lay-up, they should necessarily be reconditioned, having in mind reasonable expenditures for this purpose. The factors in favor of reconditioning them may be briefly stated as follows:

1. The crying need for the addition of these or similar vessels for the United States Lines.
2. The fact that new vessels will not in all probability be authorized by Congress; also that, if authorized, at least three years will elapse before these new vessels could be placed in service.
3. The good condition of the vessels, their suitability for the service, as well as their availability for next year's passenger season, if promptly and properly reconditioned.
4. With present first costs, a considerably greater return could be had on the reconditioning investment than on investments in new tonnage.

SUITABLE RUNNING MATES OF THE GEORGE WASHINGTON

Can these vessels with their limitations in size, spaciousness and loftiness ever be considered comparable running mates of the *Leviathan* no matter how much money be expended on them? It would seem, therefore, that these vessels should be reconditioned for running mates of the *George Washington* having first, second and third class passenger accommodations. By removing from each vessel two of the engines, auxiliaries, certain boilers, uptakes and the forward and after funnels and converting from coal to oil burners, a service speed of 18 knots may be had. Reducing the power makes available additional cubic and deadweight for the carriage of oil fuel and is favorable for effectively dealing with any question of stability, no expensive "bulges" or "blisters" being required. The economy of operating at 18 knots instead of 22½ knots should be apparent.

EACH SHIP COULD BE RECONDITIONED FOR \$3,000,000

With this arrangement nothing like \$16,000,000 would be expended in reconditioning, an estimate of \$3,000,000, exclusive of steward's equipment, for each vessel would surely be an outside figure of cost at prevailing prices. Any estimate of operating costs which is based on similar ships would show a substantial net revenue after deducting all items, including insurance, interest on investment and a high rate of depreciation, fully justifying reconditioning the vessels as outlined. Fig. 1 illustrates the graceful general character of the vessels after they have been reconditioned on this basis.

Powerful Windlass Built for Submarine Tender

FOR installation on the United States submarine tender *Holland*, which is being built at the Puget Sound Navy Yard, Bremerton, Wash., the Hadfield-Penfield Steel Company has recently completed at its Willoughby (Ohio) works a windlass of sufficient size and power not only to handle regular 2¾-inch Navy standard chain but also to lift the tail of a fleet submarine sufficiently out of the water for the replacement of a propeller if necessary.

PULL OF 1,000,000 POUNDS REQUIRED

When the design of the windlass was undertaken it was found that for the latter purpose the windlass would have to exert a pull of 1,000,000 pounds but in order to get a windlass that would exert a direct pull of this magnitude it was found that the machine would be too large for use on the vessel and, therefore, the designer suggested to the Navy Department that the chain could be led from the wildcat out through the hawser pipe and around a large sheave and then the end of the chain made fast to the bow of the vessel, the

sheave to be fitted with a hook to which the chain which was fastened to the submarine would be attached. By this arrangement the actual pull exerted by the windlass would be practically one-half that required to lift the submarine as the sheave would make a 2 to 1 purchase.

A windlass for handling 2¾-inch chain generally exerts a pull on the chain of about 86,000 pounds when used only for handling the anchor but it will be noted that this windlass must exert a pull on the two chains of something over 500,000 pounds which necessitated designing a special windlass having a ratio of gearing sufficient to produce the required pull.

As built, the windlass has 12-inch by 13-inch double cylinders with cranks set at 90 degrees and the gearing is so

Forward End of Windlass Showing Chain Pipes

arranged that by operating through one set of gears the anchors can be hoisted at the usual rate of speed while by means of clutches this set of gearing can be thrown out of use and another set brought into play which gives the required pull of 500,000 pounds at a very low speed for lifting the tail of a submarine out of water. The overall length of the windlass is 18 feet 1½ inches; the overall width, 16 feet 9¾ inches; the height from the deck to the top of the main gears, 8 feet 4 inches, and the height from the deck

View of Windlass Showing Wildcats and Gearing

to the center of the wildcat shaft, 5 feet. The net weight is 97,800 pounds.

From the illustrations it will be noted that the chain from the hawse pipe passes first under and then around and over the wildcat and down through the chain pipes, to the chain lockers below, as shown on the forward end of the windlass. This is contrary to the usual practice where the chain generally passes over the wildcat and down through the chain pipes directly under the wildcat.

General Arrangement Plans of Motorships Steelvendor and Steelmotor

M. S. Steelmotor Built for Isthmian Steamship Company by Federal Shipbuilding Company for Lake and Coastwise Service

Motorships for Both Lake and Coastwise Service

Federal Shipbuilding Company Delivers Two Diesel Engine Driven Lake Freighters Equipped with Special Revolving Cargo Cranes—Will Be Used on Coast During Winter

TWO motorships, the *Steelmotor* and *Steelvender*, designed primarily for service on the Great Lakes and St. Lawrence river, but adapted also for use in the coastwise trade during the winter months, have recently been

completed by the Federal Shipbuilding Company Kearny, N. J., for the Isthmian Steamship Lines. These ships were originally intended for the Pittsburgh Steamship Company, of Cleveland, O., but were taken over by the Isthmian Lines, who opened an office in Cleveland for their operation.

The vessels are of the single deck type with raised forecastle, straight stem and elliptical stern. The hulls are built on the transverse system of framing and have a complete double bottom from peak to peak which is utilized for carrying fuel oil and ballast.

Four watertight transverse bulkheads are fitted and the deck is trunked. The vessels were built to American Bureau of Shipping classification A1-E to meet the requirements for both coastwise and lake service. The principal dimensions are as follows:

PRINCIPAL DIMENSIONS

Length overall	258 feet 3 3/8 inches
Length between perpendiculars.....	250 feet
Beam, molded	42 feet 9 inches
Depth, molded to upper deck.....	20 feet
Load draft, canal service.....	14 feet
Load draft, coastwise service.....	16 feet

Amidships, the hull is divided into two large cargo holds which are free of all obstructions as no stanchions are fitted. Compensation for the lack of stanchions is made, however, by three deep web beams in each hold. The bilge brackets

in the holds are protected from drainage by a double bottom ceiling and the double bottom plating of 1/2-inch plate, is all flush with seam straps which will make a smooth surface for handling the steel products of which the cargo will be made up. The deck is also specially designed to carry a deck load of steel.

Each cargo hold has an exceptionally large hatch for a vessel of this size, the dimensions being 40 feet by 20 feet. The large holds are fitted so that rails and other steel products up to 65 feet in length can be handled in each hold.

To facilitate the rapid handling of cargo, each of the hatches is served by a

5-ton, 3 motor, variable-radius, fixed-base, revolving crane supplied by the Brown Hoisting Machinery Company and installed at Cleveland. In service these cranes have handled about 100 tons of finished steel products an hour. They have a capacity of 10,000 pounds on a single line with a lifting speed of 130 feet per minute with a 50-foot radius. The maximum hoist under operating conditions is 65 feet.

The cranes are equipped with Diehl motors operating on 240 volts direct current, the hoisting motor is of 50 horsepower, the rotating motor of 25 horsepower and the boom

For Rapid Handling of Cargo Electric Revolving Cranes Are Installed on Deck

PLAN AT FLAT

SECTION AT FRAME NO. 20 LOOKING FORWARD

PLAN AT ENGINE ROOM FLOOR

ELEVATION LOOKING TO PORT SIDE

motor of 15 horsepower. The hoisting and boom controllers are arranged for dynamic braking when lowering, the rotating motor is braked dynamically in both directions.

One special feature of the cranes is the method by which the booms are stayed on deck. Counterweights are lowered to the bottom of the shaft, unhooked and the boom lowered by means of the lines to the deck. The operation is accomplished rapidly when the vessel is being made ready for use.

Loading and unloading conditions, chiefly in Montreal, are given as the principal reason for the installation of these cranes.

DECK MACHINERY ELECTRICALLY DRIVEN

Power for the deck machinery and motor-driven auxiliaries is furnished by two 60-kilowatt Diehl generators driven by Worthington Diesel engines designed to develop 90 brake horsepower at 375 revolutions per minute. One of the generators is connected with an auxiliary Worthington 3-stage air compressor through a Cutler-Hammer magnetic clutch. Electric current for lighting purposes while the vessel is in port and the main generators are shut down is furnished by a 5-kilowatt Diehl generator driven by a Mianus kerosene engine. Two sets of navigating lights are permanently installed, one for use on the Great Lakes and the other for use on the coast.

All of the deck machinery in addition to the revolving cargo cranes is electrically operated, including a Hyde spur gear windlass and four Hyde mooring winches, installed for facilitating the handling of the ship in the Welland Canal and the locks of other canals. A special quadrant-type steering gear is being tried out on one of the vessels while the other is fitted with the regular hydraulic gear with the follow-up gear motor driven. An electrically-driven $\frac{1}{2}$ -ton Brunswick ammonia ice machine cools the refrigerating spaces.

PROPELLING MACHINERY

As is the custom in lake freighters, the propelling machinery is located aft. In the case of these vessels it consists of a McIntosh and Seymour four-cycle, six-cylinder Diesel engine designed to develop 750 brake horsepower at 135 revolutions per minute, direct connected to the propeller shaft. This power is designed to give the vessel a speed of about 9 knots at a 14-foot draft.

The main engine is of the trunk piston type with cylinders 22 inches in diameter and 32 inches stroke. The thrust bearing is of the Kingsbury type and the propeller is of the 4-blade built-up type of manganese bronze 10 feet diameter by 8 feet pitch.

The lubricating oil system is of the pressure type with a gravity tank provided for gravity lubrication to the bearings. The oil drains from the main engine to a drain tank located in the inner bottom. Two Worthington motor-driven rotary gear pumps each having a capacity of about 125 gallons per minute draw the oil from the drain tank through separate strainers and discharge it through a duplex strainer and two Griscom-Russell multi-whirl oil coolers to the main engine pistons.

Oil for the gravity tanks for bearing lubrication is taken from the pressure system through a valve suitably adjusted to maintain the proper pressure and flow. A settling tank and a De Laval motor-driven oil purifier of about 100 gallons per hour capacity are provided for settling and filtering the oil.

The following tanks are provided for the lubricating oil system:

- Two 300-gallon storage tanks.
- One 300-gallon drain tank.
- One 300-gallon settling tank.
- One 30-gallon gravity tank.
- Two 30-gallon drain tanks for main generator engines.
- One 5-gallon drain tank for emergency generator engine.

Fuel oil is supplied to the fuel oil pumps on the main engine by gravity through a duplex strainer from two 3-ton daily service tanks on the main deck level. A vertical simplex piston pump is provided and so piped that fuel oil may be pumped to or from any fuel oil double bottom tank or service tank.

Injection air is supplied at a pressure of 1,000 pounds per square inch by the attached compressor on the main engine, or the auxiliary compressor—driven by the after main generator engine, or, in emergency, by a Worthington emergency two-stage compressor.

Maneuvering air at 350 pounds pressure is supplied from the excess from the injection air system and by the auxiliary compressor. The air is stored in two maneuvering air tanks each having a capacity of about 250 cubic feet, giving a total capacity sufficient for about 30 starts of the main engine.

ENGINE ROOM AUXILIARIES

The main pumps are motor driven and comprise the following:

- One Worthington ballast pump, horizontal duplex, 7 inches by 6 inches.
- One Worthington fire and bilge pump, horizontal duplex, 7 inches by 6 inches.
- One Worthington circulating water pump, centrifugal, 4 inches.
- One Worthington auxiliary circulating water pump, centrifugal, 2 inches.
- Two Worthington rotary lubricating oil pumps, $4\frac{1}{2}$ -inch suction.
- One Northern Fire Apparatus Company rotary lubricating oil drain pump, 2-inch suction.

All except the lubricating oil pumps are connected to the ballast system and permit ballasting the vessel in a short time. The lubricating oil pumps are of large capacity to offset the piston cooling of the main engine by lubricating oil.

As the vessels are to be used in coastwise service during the winter months, the bilge and ballast systems are arranged for both fresh and salt water service. The other machinery is also suitable for use on either salt or fresh water.

The remainder of the pumps are of the piston type operated by steam or compressed air. These are all of Worthington make and include:

- One horizontal duplex distilled water pump, 3 inches by 2 inches by 3 inches.
- One horizontal hot water circulating pump, 3 inches by 2 inches by 3 inches.
- Two vertical duplex donkey boiler feed pumps, 3 inches by 2 inches by 3 inches.
- One vertical duplex lubricating oil transfer pump, 3 inches by 2 inches by 3 inches.
- One vertical simplex fuel oil transfer pump, $6\frac{1}{2}$ inches by 7 inches by 8 inches.
- One vertical simplex bilge and emergency fuel oil transfer pump, $6\frac{1}{2}$ inches by 7 inches by 8 inches.

An oil-fired donkey boiler with 355 square feet of heating surface is provided to furnish heat and hot water for the living quarters. The donkey boiler stack and Diesel engine exhaust pipes are located in a single smokestack above the machinery space.

The other auxiliaries include a White Fuel oil strainer, an Elliott lubricating oil discharge strainer, an Elliott circulating water strainer, a two-pass surface condenser with 75 square feet of cooling surface, a hot water storage heater, two Griscom-Russell lubricating oil coolers, a Griscom-Russell distilling set, a DeLaval lubricating oil purifier, a Schutte & Koerting injector and an oil burner for the donkey boiler. An extra large ballast line is used in the double bottom tanks. The mechanical telegraph is of a special lake type with an alarm attachment to notify both the captain and the engineer if a mistake is made in the signals.

Quarters for the deck crew are located in the forecabin, the captain and owner have staterooms in the forward deck house and the engine room crew and stewards' department are quartered in the deck house aft on the upper deck.

Motorship Crux, of 6,500 Tons Deadweight, Equipped with Burmeister & Wain's New Type Engines

Europe Developing New Types of Diesel Engines

**Manufacturers Carrying Out Experimental Work on Double Acting,
High Speed and Compressorless Types of Engines**

By Our Special London Correspondent

WHEN it is mentioned that some 40 percent of the orders placed for ships in Europe during the past six months are for vessels equipped with internal combustion engines, it will be gathered that shipowners are rapidly becoming convinced of the suitability of motor craft for their various trades. It is a notable fact, however, that Diesel engine manufacturers, even those whose motors have proved their complete success at sea, are all carrying out much experimental work, with a view to developing new and improved types.

It is now a much-debated point in shipping circles whether for vessels up to about 10,000 tons deadweight, single or twin-screw machinery should be utilized. The tendency is undoubtedly towards the employment of one engine, with the consequent saving in cost and upkeep, but some owners still join in their faith to the twin-screw plant.

For such purposes, Burmeister and Wain have re-

cently developed what they term a light engine, examples of which are to be seen in the 6,500-ton motorship *Crux* which they have just built for the Bergen Steamship Company. Apparently with this design they have succeeded in reducing the weight of the machinery to a considerable extent, for the two main engines each of 1,150 indicated horsepower weigh only 162 tons combined. Such a result is only achieved by adopting the high speed of 145 to 150 revolutions per minute but it also has the result of reducing the length of the engine room to 35 feet. The weight given, of course, excludes the auxiliary machinery, shafting, piping, ladders, etc., which bring the total engine room weight up to 312 tons.

APPEARANCE OF ENGINE CHANGED

In this new engine, the builders have greatly modified the distinctive appearance of the standard Burmeister and Wain design. The camshaft has been raised

Deck View Showing Electrically Driven Winches

to the level of the cylinder cover, enabling the valves to be operated direct, instead of long vertical push rods being necessary. This has involved a modification of the camshaft drive and all the engine controls have been removed from the center

Plan of Engine Room

of the engine to one end, a similar alteration being effected with the fuel pumps.

DETAILS OF THE VESSEL

The *Crux* has been built to Lloyd's special survey to class 100 A. 1, shelterdeck, according to the requirements of the Norwegian Laws. The principal dimensions are as follows:

Length, overall	382 feet 0 inches
Length between perpendiculars	367 feet 0 inches
Breadth, molded	51 feet 3 inches
Depth, molded to shelterdeck	34 feet 0 inches
Depth, molded to upperdeck	25 feet 6 inches
Height of double bottom	46 inches
Draft, loaded	23 feet 2½ inches
Displacement	about 9,700 tons
Gross tonnage	about 3,828 registered tons
Capacity of holds	about 403,000 cubic feet, grain
Capacity of holds	about 373,000 cubic feet, bales
Water ballast	about 1,210 tons
Total capacity of fuel	about 1,100 tons
Indicated horsepower, normal	about 2,100
Fuel consumption per 24 hours	
normal	6.5 tons

The ship is built with three complete steel decks, six watertight compartments and double bottom, the double bottom being fitted for the carriage of either fuel oil or water ballast. In a large deckhouse amidships are accommodations for the officers and a limited number of passengers while the crew's quarters are aft.

Electric radiators are fitted for heating the accommodations. For fire extinguishing an apparatus on the A. S. Lux CO₂ system is fitted with pipe connections to all the cargo holds, thus avoiding the use of an auxiliary steam boiler.

CARGO HANDLING FACILITIES

The vessel carries two masts and is provided with ten 5-ton derricks served by eight 3-ton winches. In addition two 5-ton winches are fitted aft and equipped for warping purposes. The winches are all electrically driven, and have been supplied by the Allmänna Svenska Elektriska Akto. The steering gear, which is of Brown Brothers make, is of the electric hydraulic type and is controlled from the bridge by means of a telemotor. The windlass is supplied by Clarke, Chapman and Company and is also electrically driven.

The main engines of the *Crux* are normally rated to develop 2,300 indicated horsepower at 145-150 revolutions per minute but owing to the low speed of the *Crux*, desired by the owners, the indicated horsepower was in this special case reduced to 2,100 at about 130 revolutions per minute.

The daily fuel oil consumption is 6-6⅛ tons, giving the vessel a cruising radius of about 45,000 sea miles.

AUXILIARIES

All the auxiliary machinery in the engine room, as well as the deck machinery, is electrically driven, the current being supplied by three dynamos, one of 33 kilowatts and two of 66 kilowatts driven respectively by one single cylindered and two twin cylindered auxiliary Diesel engines designed and constructed by Burmeister and Wain. The current for power purposes is supplied at 220 volts, but for lighting and heating purposes this is transformed down to 110 volts by means of a motor generator.

Any one of the dynamos is sufficient to supply the necessary current required for normal working at sea, but two, or even all three, have to be in operation when the vessel is maneuvering in and out of harbor with the maneuvering compressor running or when loading and discharging cargo.

The machinery weights are as follows:

Main engines	162 tons
Auxiliary engines	35 tons
Auxiliary machinery	8.5 tons
Reservoirs	20 tons
Shafting, complete with all accessories including reserve propeller	41 tons
Ladders, grating, floor plates, lifting gear, spare parts, engine room ventilators, telegraph gears, special tools, etc.	20 tons
All piping clear of engine and including bilge and ballast piping, bottom valves, etc.	18 tons
All electrical material inside engine room	3.5 tons
Water in pipings	4 tons
Total	312 tons

TRIAL TRIP

The trial trip of the *Crux* was run on July 9 in the Sound at Copenhagen, when a mean speed of 10.94 knots was obtained with a fuel consumption of 0.284 pound per indicated horsepower hour, the net calorific value of the fuel used being 18,100 British thermal units per pound. The fuel consumption given above includes the consumption of the auxiliary engines producing the necessary current for driving the auxiliary machinery, the steering gear and the electric light.

Another new engine, which the same builders have just developed, is one specially designed for the propulsion of large yachts. The first example is seen in Mr. Edward Hutton's fine 800-ton yacht *Hussar* which is described elsewhere in this issue.

A NEW HIGH-POWERED SUBMARINE ENGINE

An interesting development has recently been made by the Fiat Company of Turin, who have purchased the Ansaldo San Giorgio Company's Diesel engine works. A two-cylinder experimental submarine engine has been built developing 1,000 brake horsepower or 500 brake horsepower per cylinder.

It is of the two-cycle type with controlled port scavenging, and its main peculiarity lies in the fact that it is almost wholly of cast steel, except for cylinder liners, pistons, connecting rods, crankshaft and camshaft. It runs at about 350 revolutions per minute and is claimed to have a remarkably low weight to power ratio. The only valve in operation in each cylinder is the centrally-placed fuel inlet valve, apart from the scavenge control valve which prevents the scavenging air being admitted to the cylinder, until the exhaust ports have been partially uncovered by the piston in the course of its downward stroke.

The builders will utilize a somewhat similar design in their mercantile engine of the slow speed type and, with extensive employment of cast steel for the engine crank chamber, cylinder jackets and cylinder covers, has attracted considerable attention, since the tendency has of late been towards the exclusive employment of cast iron for this purpose.

The Fiat Company is about to build its first experimental double-acting two-cycle engine on which plans are now well advanced, and incidentally it may be added that at least half a dozen of the leading Diesel engine manufacturers are now engaged upon this problem. The British Admiralty is experimenting with a double-acting two-cycle motor of high power, with the object of its employment for submarine work.

NEW ENGINE PLACED ON MARKET

After a period of prolonged experiments, a new type of Diesel engine has been placed on the market by Sulzer Brothers which, however, is not intended to replace their ordinary design but is only being built in sizes of 200 brake horsepower and under. It operates on the two-cycle principle and employs crank chamber compression, although the 200 horsepower four-cylinder size is built alternatively with separate scavenging pumps. The main point of importance in the design is the elimination of the injection air compres-

sor. A mechanically operated pump delivers the fuel to a special type of valve in the cylinder head. This is automatic so that there are no mechanically operated valves, while the fuel pump works at low pressure, since the oil is delivered to the valves at the commencement of the compression stroke. This engine on trials has shown a fuel consumption of about 0.41 pound per brake horsepower hour, which is equal to that achieved with much larger motors of ordinary design. The cost of manufacture is considerably less than that of the air injection type, and although it is stated that there is no present intention of building it in large powers for the propulsion of ships, this possibility is by no means ruled out.

Another new Diesel engine is now being standardized by the A. E. G. Works in Berlin for installation in motorships built by the Deutsche Werft at Hamburg. This is virtually a long-stroke Burmeister and Wain design but is of high power, developing 3,000 brake horsepower in six cylinders. It is hoped to construct similar types with still greater output, but where powers of more than 4,000 brake horsepower are required on single-screw ships, no doubt the new Burmeister and Wain double-acting motor will be adopted.

Inland Waterways Prove Most Economical Means for Transporting Novel Shipment to St. Louis

A NOVEL shipment by water was recently made from the old Hickory Powder Plant at Jacksonville, Tenn., to St. Louis. Six immense tanks already erected at the Old Hickory Plant were purchased by the Monsanto Chemical Works for their Plant B in East St. Louis. As

Photograph by Kadel & Herbert, N. Y.

United States Battleship Indiana, Partially Completed at New York Navy Yard, Brooklyn, N. Y., Which Is About to Be Dismantled and Scrapped in Accordance with the International Disarmament Treaty

Tanks Loaded on Barge for Transportation on Western Rivers

these tanks have a diameter of 20 feet and a height of 12 feet, and weigh approximately 13 tons each, their size made it impractical to ship them by rail. It would first have been necessary to dismantle them and later reassemble them in their new location, incurring unnecessary expense. It was possible, however, to ship them by barge without dismantling them.

From the loading point the barge descended the Cumberland River through a series of locks to the Ohio, thence down the Ohio to the Mississippi, which it ascended to East St. Louis, where the tanks were unloaded and installed in their new locations.

THE BUREAU OF NAVIGATION, Department of Commerce, reports 84 sailing, steam, gas and unrigged vessels of 25,217 gross tons built in the United States and officially numbered during the month of August, 1923.

Three Masted Diesel Auxiliary Yacht Hussar IV Under Sail

Diesel Auxiliary Schooner Yacht Hussar IV

**Latest Addition to New York Yacht Club Fleet Built
Abroad from Designs by Cox and Stevens of New York**

ONE of the most interesting events of this year's yachting season was the arrival on this side of the Atlantic of the new three-masted auxiliary schooner yacht *Hussar IV*, designed by Messrs. Cox & Stevens, naval architects of New York, and built under their supervision by Messrs. Burmeister & Wain, of Copenhagen, Denmark, for Mr. Edward F. Hutton, of the New York Yacht Club.

Captain Carl G. Muller, who is in command of the *Hussar IV*, reported that on her trip across she encountered extremely heavy weather but that the new vessel proved herself an excellent seaboat, carried her sail well and made a very quick passage considering the conditions. The weather for the most part was unfavorable, heavy winds and rough sea being encountered, but notwithstanding this fact the voyage from Dover to New London was made in fourteen days, an excellent performance under the circumstances.

GENERAL CHARACTERISTICS

This new schooner is one of the largest auxiliary vessels in the New York Yacht Club fleet, her dimensions being:

Length overall	204 feet 6 inches
Beam	33 feet 0 inches
Draft	14 feet 6 inches
Displacement	826 tons
Indicated horsepower, auxiliary engine	900

She is equipped with a 900 horsepower Burmeister & Wain Diesel engine placed well forward of amidships and driving a two-bladed feathering bronze propeller which when folded

into its recess forms practically no obstruction to the speed of the yacht, but when in use can drive the vessel continuously at a speed in excess of 11 knots.

MAIN ENGINE

In order to reduce the weight of the engine, the speed has been increased to 300 revolutions per minute and the engine develops 900 indicated horsepower or about 700 brake horsepower. The camshaft is at the top of the engine with ahead and astern cams side by side. Reversal is effected by turning the shaft on which the valve levers are mounted, moving the camshaft fore and aft, and then bringing the valve lever again in contact with the cams, thus allowing the astern cams to come into action. The whole operation is effected automatically by a servo-motor controlled by means of a small reversing lever, and there are two further levers for starting and speed control. This engine is of the trunk piston type, the cylinders being carried direct on a box-form crankcase.

AUXILIARIES

The fuel tanks, located below the cabins aft, have a capacity of 64 tons of oil. The daily fuel consumption with the engine running at full speed is $2\frac{3}{4}$ tons for all purposes and the radius of action of the vessel is 7,000 sea-miles without using the sails. There are two auxiliary Diesel engines, each of 50 brake horsepower and driving a 33 kilowatt dynamo.

Plan of Engine Room

The other auxiliaries in the engine room comprise electrically driven bilge and fire pumps, fuel oil transfer pumps, fresh-water pumps, a single auxiliary maneuvering air compressor, sanitary, fresh-water, cooling and lubricating-oil pumps, in addition to which a small heating boiler is installed on the starboard side.

The electric light installation comprises about 400 lights, and there is a storage battery of 100 Edison cells, having a total capacity of 300 ampere-hours.

HULL AND RIG

In designing the hull for use on extended cruises, a flush deck vessel with clipper bow and moderate overhang aft was adopted, with a raised poop to provide a dry space on deck

foremast was stepped further aft than usual and four lower head sails are carried, an arrangement that has worked out extremely well. Although by no means under-sparred the masts of this vessel are of such a height that she can pass under the Brooklyn Bridge without sending down her topmasts, which is a valuable asset in the case of a vessel which will be used around New York waters.

The weather deck is of heavy teak planking and the deck-houses, of which there are two, are also of teak, as are the rails, skylights and all other fittings of like character.

The after deckhouse starts at the break of the poop and forms a comfortable living room, affording also access to the owner's and guests' quarters on the lower deck as well as

(Continued on page 624)

for the owner and his guests when at sea in heavy weather. The proportions of the hull were selected with a view not only to comfort and seaworthiness, but also having in mind the serious disadvantage of excessive draft. With the very moderate draft of 14 feet 6 inches the *Hussar IV*, while having an excellent form for driving under sail as well as power, is able to enter any of the harbors which the owner expects to visit.

The vessel was built complete according to Lyold's highest classification for a rugged and substantial craft. The vessel is sparred as a three-masted schooner, having only a moderate sail plan but carrying sufficient canvas so as not to be sluggish when under sail. A rather unusual sparring arrangement was determined upon in order to reduce the size of individual sails, by which the

Six Cylinder Burmeister & Wain Diesel Engine Installed on Yacht Hussar IV

Telescopic Conveyor to Speed Up Vessel Loading and Discharging on Pacific Coast

HANDLING cargo by the old method of ship's sling may be discarded for a new invention that is expected to revolutionize the handling of freight, in the opinion of the Port Commission of Seattle, Wash., whose chief engineer, George F. Nicholson, is the inventor of what is known as a ship cargo telescopic conveyor.

The Port of Seattle, in connection with its planning and construction program of its marine terminal system, has adopted the policy of providing these harbor facilities with

or at two ends and the center. The estimated weight is $3\frac{1}{2}$ tons and it can be easily handled by the ship's boom. The motor equipment consists of a 10 horsepower squirrel cage, 3 phase, 60 cycle, 440 volt, alternating current induction motor, running at 1,200 revolutions per minute. Silent roller chain drives are used for both conveying and telescoping conveyor.

LOADING CAPACITY DOUBLED

This equipment has a capacity of 125 tons per hour at a speed of 75 feet per minute and will double the capacity for loading and unloading vessels. With Seattle's present method of unloading canned salmon, for instance, the capacity averages 800 to 1,000 cases, while the new conveyor will handle 2,000 cases. It can handle boxes, bales and

Sketch Showing Application of Ship Cargo Telescopic Conveyor

the most modern and efficient mechanical handling appliances, and among this handling machinery will be found several specialized labor-saving devices which have been planned and constructed by the port's engineering department, headed by Mr. Nicholson. The latest equipment is a ship cargo telescopic conveyor, which is shown in the illustration.

A CONVEYOR WITHIN A CONVEYOR

This equipment is actually a conveyor within a conveyor, it being lengthened by extending the interior conveyor, this being done not by man labor, but by power, which arrangement makes it very convenient and economical to operate. The length of this conveyor extended is 45 feet and the length collapsed, that is, with the extension raised to the highest point, is 29 feet—the width over all is 5 feet 6 inches, which shows that it is a very compact piece of machinery. It can be supported at both ends, or at one end and the center

sacked goods up to a maximum weight of 500 pounds and to a maximum size of $2\frac{1}{2}$ feet by 5 feet. The commodities that it is expected to handle are cased salmon, cased milk, in fact, cased goods of all kinds, including sugar, beans, rice, etc. In the case of bales over 500 pounds, such as gunny bales, also rattan, bamboo, bulky furniture, etc., these, of course, would be handled by the ship's boom, which can easily be done, as the conveyor only covers a small area of the hatch opening.

Another use that can be made of this type of conveyor is for transferring cargo from one portion of the transit shed to another, and from ship to transit shed and to the warehouse. The estimated cost of this equipment is \$2,400 per conveyor, including extension and full equipment. It is expected by the port of Seattle that this will revolutionize on the Pacific Coast the handling of freight from the ship's hold to the wharf and vice-versa, especially Oriental import cargo from the Far East.

U.S.S. Colorado

Electrically Propelled 21-Knot Battleship Colorado

THE U. S. S. *Colorado*, the fifth battleship to be equipped with electric drive, was commissioned for active service in the navy at the yard of the New York Shipbuilding Company, Camden, N. J., on August 30. The *Colorado* is a sister ship of the *Maryland* and the *West Virginia*.

*Capt. Belknap
Reading His
Instructions*

The newest addition to the navy has a length overall of 624 feet; breadth on waterline 97 feet, normal displacement 32,600 tons, the main engines being two 18,000 horsepower Westinghouse turbo-electric generators and four 8,000 horsepower Westinghouse motors, each connected to a propeller shaft. The ship will be an oil burner, developing a speed of 21 knots.

ARMAMENT

Like the *Maryland* and the *West Virginia*, the *Colorado* carries

eight 16-inch 45-calibre guns, mounted in four turrets. Her secondary battery for defense against destroyers, submarines and other light craft consists of twelve 5-inch 51-calibre guns. In addition, she carries two 21-inch submerged torpedo tubes and eight 3-inch high-angle guns for defense against aircraft. Her complement consists of 1,400 officers and men.

The vessel will be commanded by Captain Reginald Rowan Belknap, U. S. Navy, who recently served on the staff of the Naval War College at Newport, R. I.

THE THREE "COLORADOS"

The new battleship *Colorado* is the third ship in the American Navy to bear that name. The first, named for the Colorado River, was a wooden steam frigate of 3,400 tons displacement, mounting 40 guns, launched at the Norfolk Navy Yard on June 19, 1856. The second was an armored cruiser of 13,680 tons displacement and 22 knots' speed with a main battery of four 8-inch guns launched at Cramp's Shipyard, Philadelphia, April 25, 1903. In 1916, with the authorization of the new battleship *Colorado*, her name was changed to *Pueblo*.

PROPELLING MACHINERY OF THE NEW COLORADO

The electrical propelling machinery of the new *Colorado* is described by W. E. Thau, marine engineer of the Westing-

The Forward Twin Sixteens

house Electric & Manufacturing Company, which supplied the machinery, as follows:

The four propellers are electrically driven by direct connected, two-speed, wound secondary, induction motors, supplied with power by two turbine generator sets. A battery of eight oil fired, watertube boilers supplies steam at 265 pounds gage to the turbines. All engine room auxiliaries necessary to the main propulsion, such as the main condenser circulating and condensate pumps, the auxiliary condenser condensate pumps, the lubricating and governor oil pumps, oil cooler circulating pumps, and the main motor ventilating blowers are electrically driven by direct current motors. The direct current for those auxiliaries necessary to the propulsion, as well as the excitation of the main generators is supplied from one of the three 300 kilowatt geared turbine direct current generating sets in each engine room.

The power generating machinery is located in two engine rooms, one being forward of the other, and both being forward of the control room. The turbine generators are mounted directly above the condensers. On the same flat with the main generators are mounted two 300 kilowatt geared turbine direct current condensing sets and one non-condensing set, all being of the 3-wire type, supplying electric power at 240 and 120 volts. The condensers with their auxiliaries are mounted on the lower machinery flat or pump room. The switchboards for controlling the 300 kilowatt sets are mounted at the ends of the engine rooms.

All control equipment and other apparatus necessary for the complete control of the propelling machinery is contained in the control room, which is located between the engine rooms and motor rooms. The *Colorado* is the first turbine electric driven vessel to have remote electric speed control. All operation incident to the maneuvering of the main turbines, except the actual starting when preparing to get under way, is done electrically from the control room. This is a very unique arrangement, in that it eliminates all mechanical and hydraulic connections between the turbines and the control station.

MAIN MOTORS

Each propelling motor is capable of delivering a maximum of 8,375 horsepower at a speed of approximately 185 revolutions per minute. The motors are of the induction type, and are wound for 2-speeds at full frequency, there being a 24 pole and a 36 pole winding. The primary or stator has two independent windings, one for each set of poles. The rotor has a 3-phase, two parallel, star-connected winding, having balancer connections operating as such on the 24 pole winding. The 24 pole winding is connected to three slip rings. When the stator is connected to the 36 pole

winding, the balancer connections form short-circuit paths for the rotor conductors, thus forming an ordinary squirrel-cage winding having straps instead of resistance rings to connect the rotor conductors together.

The design of the motors incorporates all special features required by marine service. The mechanical construction of the motor is of the self-contained type, in which the bearings are carried by suitable brackets which fit into recesses in the stator frame. The entire motor is supported by feet cast integral with the frame on either side. The bearing housings are adjustable radially by means of jack screws in the brackets, and, after being adjusted, are bolted rigidly to the bracket.

The ventilation is supplied by duplicate, direct current, motor driven, exhaust blowers, each capable of delivering a maximum of 12,500 cubic feet of air per minute. In addition to these separate blowers, the rotor of the motor is provided with fan vanes which assist in the ventilation, and which are capable of supplying sufficient air to enable operation for brief periods without the separate blowers. The separate blowers are mounted on top of the motors, and are arranged to draw the air through the motors and discharge it through suitable ducts to the deck.

To facilitate inspection and repair, suitable tracks and disassembling gear are provided, which enable the stator to be moved clear of the rotor.

MAIN GENERATORS

Each main generator is capable of delivering a maximum of 15,000 kva. at approximately 36.5 cycles. The generators are designed and constructed in accordance with standard land practice, except that the rotor is of the totally enclosed type.

The air for ventilating the generators is supplied to the machinery space by means of separate ventilating blowers.

The air thus supplied is drawn from the lower machinery space through an inlet at the bottom of the generator, through the end bells, entering the machine at each end of the rotor, and is discharged through an outlet duct to the deck.

The rotor consists of a solid steel forging having radial slots for receiving the windings. The winding consists of a series of turns of bare copper strap and the insulation is entirely mica and asbestos. After winding, the coils are very substantially braced, in order to prevent any possible movement.

The propelling motors and generators are provided with thermocouples for measuring the hot spot temperatures. These thermocouples are connected to a central potentiometer board in the control room where the readings may be recorded.

To prevent the motors

Hoisting the Flag for the First Time on the New Battleship Colorado

S. S. Colorado: (1) One of the 8,000 Horsepower Propeller Motors; (2) Switchboard in the Engine Room; (3) Control Room, Where a Crew of Six Men Ordinarily Handle the Vessel; (4) Motor Driving One of the Ship's Cranes; (5) One of the 18,000 Horsepower Turbo-Generators

and generators from sweating when idle, heaters are provided, the motors being heated electrically, and the generators by means of steam coils.

TURBINES

The turbine is of the combined impulse and reaction, semi-double-flow type, allowing complete expansion of the steam in one cylinder. An exhaust connection is provided at each end of the turbine, from whence the steam is conducted to a single condenser.

The turbine speed is regulated by the governor valve only, hand valves being used merely to obtain the best economy, and to prevent overloading the boilers at various standard speeds.

SPEED CONTROL

Briefly, the speed control system consists of a governor driven directly from the turbine shaft through suitable gearing. The governor is essentially a dead weight governor, in

Sketch Showing Location of Propelling Machinery

which the dead weight is replaced by a hydraulic piston, resulting in a type of governor capable of functioning over a wide range of speed by varying the hydraulic pressure on the piston. The speed is adjusted hydraulically by means of a motor operated control valve in the engine room, which regulates the oil pressure. The control for the motor which operates the valve is located in the control room, and hence enables the speed of the turbine to be adjusted electrically from the control room. The position of the speed control element is transmitted electrically to an indicator in the control room, thus enabling the operator at all times to know the position of the turbine speed control system. A double seated poppet valve located on the main steam inlet to the turbine is controlled through a floating lever oil pressure relay system from the main governor, and this valve controls the amount of steam as required to maintain the speed for which the system is set. The governor control valve is also operated through a suitable oil pressure relay by a separate over-speed governor secured to the end of the turbine shaft. In addition, this over-speed governor also operates the main throttle valve in case of necessity.

In order to limit the power input to the turbine on overload conditions to an amount which will prevent excessive overloads on the machinery, and also prevent priming of the boilers, a power limit stop is provided. This is arranged to limit the travel of the governor linkage in the direction which admits more steam. The position of the stop is adjusted electrically from the control room through a system of gearing operated by a small motor. In order that the operator may know when the governor control system is approaching the setting of the power limit stop, an arrangement of pilot lights is provided. The switches for these lights are arranged on the governor linkage that a white light indicates the position for which the stops should be adjusted; a white and red light indicates when the governor is approaching the limit of the stop; and a red light indicates when the stop has been engaged by the governor linkage.

In operation, this system functions as follows: The speed of the ship is set from the control room for any given standard by means of the hydraulic speed-control system. The power limit stop is then adjusted to limit the motor speed to a few revolutions above that corresponding to the standard speed. Should an overload occur from turning or from any other cause, the speed-control governor will tend to maintain a constant speed by admitting more steam. However, as the governor linkage has only an additional limit of travel corresponding to the few revolutions increase in motor speed, the steam which can be admitted to the turbine is, therefore, limited, and consequently the overload has a fixed value for any given condition.

By providing the motors with two sets of windings, more economical operation can be obtained at low speed than would be the case with a single winding motor. For a given motor connection, the propeller speed is varied in the same manner as in the case of a geared turbine drive, that is, by throttling the turbine. The double winding on the motor permits the turbine to be operated at relatively high average speeds for cruising and full speed conditions. This arrangement, together with the arrangements for carrying the load of all four screws on a single generator at reduced power results in fairly flat steam consumption rates for all operating conditions.

MAIN CONTROL

As in the case of any other drive, the control for the electric drive is operated under orders from the bridge. All controlling apparatus necessary for the operation of the propelling machine is either located in the control room, or arranged for remote operation from the control room, except the actual starting of the turbines when preparing to get under way. The main circuits are handled by means of manually operated oil circuit breakers. All circuit breakers

Why Americans Pay Greater Panama Canal Tolls

Shipowners, Captains of Vessels and Naval Architects Have
Not Learned to Take Full Advantage of Our Tonnage Laws

By M. C. Davis*

THE statement has often been made that an American ship pays more tolls to transit the Panama Canal than a British or foreign ship of the same deadweight tonnage. This statement unfortunately is true, and the purpose of this article is to explain the reason for it, and also to suggest a remedy.

At the time of the construction of the canal, Professor Emery R. Johnson was directed to compile a set of rules of measurement which would be impartial to all vessels, with a view of using them for the assessing of tolls for this canal. It might be said here that these rules are the fairest and most impartial ever compiled with regard to measurement of vessels. They are called "The Measurement of Vessels for the Panama Canal."

The President's Proclamation of November 13, 1912, stated that merchant vessels carrying passengers or cargo would be charged \$1.20 per net vessel ton, each consisting of 100 cubic feet to the ton.

The Act of Congress of August 24, 1912, provided that tolls may be based upon the gross or net registered tonnage, but based upon the net registered tonnage for ships of commerce the toll shall not exceed \$1.25 per net registered ton.

MUST BE MEASURED IN ACCORDANCE WITH RULES

This matter was referred to the Attorney General who ruled that the \$1.25 net ton meant: \$1.25 times the U. S. net registered tonnage for American vessels and its equivalent for foreign vessels. The result of this is that a vessel is charged \$1.20 times her Panama Canal net tonnage (as derived by the rules called "The Measurement of Vessels for the Panama Canal") provided this amount does not exceed \$1.25 times the vessel's U. S. net registered tonnage or its equivalent in the case of foreign vessels as found on board the vessel at the time that she makes application for transit through the canal. This does not mean that the vessel's tolls will not exceed \$1.25 times her U. S. net register, unless the different spaces in the vessel are in strict accordance with the U. S. rules for measurement of vessels and the latest rules, decisions and interpretations of the Commissioner of Navigation. A vessel whose American register shows her net tonnage to be 5,000 tons, may be charged as high as 5,500 tons for her transit through the canal, this difference being due to the fact that the captain is not familiar with the rules. For instance he might have had hinges placed on the hull opening plates or inserted gaskets therein, thereby disqualifying the entire space from exemption and at the same time decreasing the propelling power allowance by several hundred tons.

As has been previously stated, the rules called "Measurement of Vessels for the Panama Canal" in themselves are fair and impartial and they need no further comment in this article. The U. S. rules of measurement for vessels, however, have a large number of loop holes whereby the net tonnage on the register may be decreased by conforming to certain technicalities of these rules. As the tolls for a vessel transitting the canal cannot exceed \$1.25 times this net register, it is apparent that the lower the net tonnage shown in this register is, provided said spaces are in accordance with the rules, the less tolls the vessel pays in transitting the canal. These rules provide that if certain spaces on board a

ship have certain means of closing, which, technically are not watertight, the entire space shall be exempt from the gross and net tonnage of the vessel. In this respect the rules are practically an exact copy of the British rules, with the exception of the exemption on passenger vessels of cabins or staterooms situated on or above the first deck, which is not a deck to the hull. In this the American rules go the British one better in the exemption of all cabins and staterooms situated in these spaces.

SPACES THAT CAN BE EXEMPTED ON CARGO VESSELS

The spaces that can be exempted on cargo vessels when properly fitted with tonnage openings are: The forecastle, bridge and poop when said spaces are fitted to carry cargo in this type of vessel; and the entire shelter deck where fitted to carry cargo in the case of shelter deck vessels.

BRIDGE SPACE

This space, when added to the register is the largest one which can be exempted in the "three island" type of vessel. This usually runs from 300 to 600 tons. When this space is included in the register, the vessel usually obtains what is called the 175 percent propelling power deduction which means the actual space of the engine room and fireroom including shaft-alleys and escapes, and a portion of the space above the fireroom and engine room when properly certified and authority obtained from the Commissioner of Navigation for adding same and 75 percent of this total space in addition for bunkers. This deduction is from 200 to 800 tons less than the 32 percent propelling power deduction, which means 32 percent of the gross tonnage of the vessel. The application of this deduction will be taken up later in this article. However, it can readily be seen that when a vessel has the bridge space included and the 175 percent propelling power deduction, it would be of great advantage to the ship to have the tonnage openings installed, thereby exempting the entire space and also obtaining the more advantageous propelling deduction, namely, 32 percent of the gross tonnage.

DOES NOT BAR CARRIAGE OF CARGO

It must be understood that when tonnage openings are fitted to these spaces, they do not bar the carrying of any kind of cargo in this space as they are for the express purpose of making these spaces technically comply with the law regarding them. The question might readily be asked here: Why do they not change such a law? The answer is: That England and other foreign countries, many years ago adopted this method in order to encourage their merchant marine thereby reducing the harbor dues, lighthouse, wharfage and other dues in foreign countries where they are based on the gross or net tonnage of the vessel. The only thing left for the United States to do out of self-protection was to adopt similar rules for its vessels.

The writer has reduced the tonnage on some vessels of this type as high as 1,200 tons by simply having these tonnage openings installed, thereby saving the operators \$1,600 on each and every transit through the canal; and the difference due to the reduction of this tonnage in harbor dues, dry docking and so forth in all cases where the charges are based on the gross or net registered tonnage.

* Formerly chief admeasurer, Pacific entrance to Panama Canal.

The entire space in the bridge can be exempted with the exception of any space within it which is entirely closed in, such as a storeroom or refrigerator room. Machine shops and refrigerating machinery located in this space are exempted under the rule which exempts all machinery above the tonnage deck. In order to have this space exempted, it is necessary to install two tonnage openings in the after end of the bridge either in the bulkhead or in the two after-doors when they are large enough to permit the installation of openings of the size required by law. These requirements are that this opening must be not less than 3 feet wide and 4 feet high and that the bottom of the opening must not exceed 24 inches from the deck. It might here be stated that the American Bureau rule required that this opening must be at least 18 inches from the deck so this leaves a lee-way of 6 inches in which to lay off the bottom of the opening.

This opening can be closed by a steel plate preferably of

Fig. 1.—Method of Obtaining Exemption and at Same Time Retaining Access by Door in Tonnage Opening

the same thickness or thicker than the bulkhead or door where it is cut out. Angle-iron stiffeners must be installed on the inside edge of the opening with the toe of the angle placed next to the opening. The plate must be held in place by hook bolts, the hook of which grasps this angle-iron. The hole for these bolts must only be through the plate and not in the bulkhead and must be spaced not less than 12 inches apart, measuring across the shortest distance from center to center. One of the most serious mistakes that have been made in this connection has been the spacing of these bolts $11\frac{3}{4}$ or $11\frac{7}{8}$ inches apart. *One bolt thus spaced disqualifies the entire space from exemption*, due to the fact that the rule says that the opening must be at least 3 feet by 4 feet and that it is impossible to get four bolts across the top spaced 12 inches apart. It is, therefore, advisable to make the

COMPARISON OF TONNAGE BEFORE AND AFTER INSTALLING TONNAGE OPENINGS IN BRIDGE SPACE OF S. S. JOHN ADAMS.

	Before.	After.
Underdeck tonnage	7,203.09	7,203.09
Forecastle	112.56	112.56
Bridge	567.50	91.20
Poop	69.76	69.76
Round houses	186.51	186.51
Chart houses	7.17	7.17
Radio houses	4.73	4.73
Excess hatchways	48.20	50.58
Light and air	89.69	84.13
Gross tonnage	8,289.21	7,809.73
Deductions.		
Crew's space	237.37	237.37
Master's cabin	26.50	26.50
Anchor gear	16.40	16.40
Boatswain's stores	49.17	49.17
Chart house	7.17	7.17
Radio house	4.73	4.73
Propelling power (actual space)		
175%	1,800.01	32%* 2,499.11
	2,141.35	2,840.45
Gross	8,289.21	7,809.73
Deduction	2,141.35	2,840.45
Net tonnage	6,147.86	4,969.28
	4,969.28	
Net saving in tonnage	1,178.58	

*By this alteration the engine room space was made to exceed 13 percent of the new gross tonnage, thereby allowing the vessel the 32 percent propelling power deduction.

opening 38 inches by 50 inches, thereby gaining 2 inches to allow for the thickness of the bolts.

GASKETS CANNOT BE USED

Extreme care should be exercised in cutting the openings of the plate and the fitting of the angle-iron in order to see that they are as true as possible. Under no condition can gaskets of any nature be used. Not even a red lead and putty gasket can be used in making up this joint. There is, however, no objection to a coat of red lead being applied as a preservative of the metal. Under no condition is this plate to be fitted with hinges as it then becomes a permanent means of closing and is immediately disqualified as a tonnage opening.

In the event that there is a center line bulkhead or partition within this space, a similar opening must be installed or one in which two channel irons are fitted at the sides of the opening and closed with suitable shifting boards. If desired this method can be used instead of the steel plates in the after bulkheads. This method is almost universally used for tonnage openings in British vessels. However, *the fitting of both methods in the same space has recently been ruled by the Commissioner of Navigation as sufficient reason to disqualify this space from exemption.*

When the watertight doors on the after end of this space are of sufficient size, the steel plates may be fitted in same as shown in Fig. 2. This method has been approved by the Commissioner of Navigation and qualifies the space for exemption. At the same time it furnishes a ready means of access to the exempted space. In the event that it is impossible to fit two of these openings in the after end, one opening may be fitted in the center of the bulkhead or on the side, provided there are two freeing ports on each side at least 18 by 18 inches and a suitable number of scuppers, three on each side being considered a suitable number, draining from the above-mentioned space. When the space is so fitted, it will be entitled to exemption.

It will be noticed that no mention has been made for tonnage openings on the forward end of the bridge space for

the reason that the rules only require two openings to qualify the space for exemption. It is difficult to make openings in the forward bulkhead tight enough to prevent water getting in, as it is exposed to the more severe action of the sea in rough weather.

FORECASTLE

In order to exempt a portion of this space, it is necessary that it have a large space suitable for cargo and not occupied by quarters, lamp room, boatswain's stores and so forth. As a rule this space is not sufficient to warrant an installation of tonnage openings except in the case where the bridge space and possibly the poop have been exempted, and there is not sufficient space in the engine room, fireroom and space above these which is called, "light and air," to qualify the vessel for the 32 percent propelling power deduction. If it is necessary to exempt this space, it can be done by installing the same type of tonnage openings described above and in accordance with the instructions for installation of the same in the bridge space. In case, however, that only one opening is fitted, either in the center or on the side, it only requires scuppers and not freeing ports.

POOP

This space, like the bridge and forecastle, may be exempted, if the cargo space is large enough to warrant the installation of tonnage openings, in which case openings as described above for the bridge may be installed as required. The same exception applies where one opening is fitted as is specified above for the forecastle.

The classification society, however, requires that the open-

Fig. 2.—Method of Obtaining Exemption and at Same Time Retaining Access by Tonnage Opening in Door

Fig. 3.—Method of Obtaining Exemption and at Same Time Retaining Access by Door at Side of Tonnage Opening

ings in this space be fitted with shifting boards and channel irons.

SHELTER DECKS

In the case of shelter deck vessels, the entire cargo space in the shelter deck may be exempted from the gross and net tonnage amounting to from 1,000 to 1,800 tons, according to the size of the vessel, by having what is commonly known as a tonnage hatch installed at a suitable point, either at the forward or after end of the deck. If situated aft, the distance from the after edge of this tonnage hatch and the after side of the stern post must not be less than one-twentieth the registered length of the vessel; if the opening is placed forward, the forward side of hatch must not be less than one-fifth the length of the vessel from the stem.

This tonnage hatch must be not less than 4 feet long and the width must be at least equal to that of the after cargo hatch on the same deck. The coaming in this hatch must not exceed 12 inches mean height above the deck and must be fenced in with guard rails and stanchions, the latter being so fitted as not to lend themselves to battening down the opening. If portable wooden covers are fitted, the lashings, if any, beneath, for holding them down are to be of hemp. All openings in the upper deck are to be provided with the proper means for closing and battening down, but the installation of cleats in this connection disqualifies this entire space from exemption. In addition to this, there must be a freeing port of suitable size (at least 18 inches square or larger) on each side and abreast the deck opening and the bottom of these openings must not be over 12 inches from the deck. A suitable number (at least three on each side) of scuppers, not less than $3\frac{1}{2}$ inches in diameter distributed throughout the shelter deck space must also be fitted.

When this hatch is situated aft, there must be at least two openings in all transverse bulkheads in the 'tween decks forward of the tonnage hatch to entitle the space to exemption. These openings must comply as regards dimensions, and height of coamings, if any, with the requirements as given for the openings to qualify the bridge space for exemption. The openings in the forward bulkhead of the well under the tonnage hatch and in all transverse bulkheads must be closed with the channel bars at the side of the opening fitted with shifting boards as described above. *The steel plates as described for the bridge space will not qualify this space for exemption.*

PASSENGER ACCOMMODATIONS

In accordance with the instructions for the measurement of vessels, no part of any vessel will be measured for tonnage that is used for cabins or staterooms constructed entirely above the first deck which is not a deck to the hull. In this case, however, these cabins and staterooms in order to enjoy this exemption must be set aside exclusively for the passengers, as any space occupied by officers or other members of the crew, wherever situated, must be included in the gross tonnage and deducted from the net when so entitled.

PROPELLING POWER DEDUCTION

There are two methods of arriving at this deduction according to the actual size of the engine room and fireroom, and that portion of the space commonly known as "light and air," which is the space above the crown of the engine and fireroom when used for the admitting of light and air to these spaces. When the total engine room and fireroom space is less than 13 percent of the gross tonnage of the vessel, 175 percent (that is the actual space plus 75 percent of the same) is allowed as the propelling power deduction, the 75 percent being allowed for the bunker space. When the total of these spaces exceed 13 percent of the gross tonnage, 32 percent of the gross tonnage is allowed as the propelling power deduction.

In this connection, in cases where actual engine room and fireroom space is less than the 13 percent, but can be made to exceed the 13 percent by adding a portion or all of the light and air space; it is necessary to submit a written request from the owners to the Commissioner of Navigation that this space be so allowed. This request must be accompanied with a description and sketch or tracing, giving the measurements thereof and the certification by the collector of port that such space or spaces are reasonable in size and are for the sole purpose of machinery or for the admittance of light and air to the machinery. When this authority is obtained this space must be added to the gross tonnage in order that same may be allowed as machinery space.

In the case of oil burning vessels having bonafide settling tanks situated outside the confines of the engine room or fireroom, they may also be added to the engine room space by obtaining authority from the Commissioner of Navigation in the same manner as required for light and air.

It will be readily seen that in the case of a vessel whose actual engine room and fireroom amounts to about 11 percent of the gross tonnage of the vessel, it is very beneficial for the owners to make application for sufficient light and air to be added to bring the engine room up to 13 percent, thereby securing the 32 percent deduction and reducing the net tonnage from 300 to 700 tons according to the size of the vessel.

The 32 percent deduction is approximately equivalent to an engine room of from 19 to 20 percent of the gross tonnage of the vessel. For this reason, if the engine room and fireroom combined exceed 20 percent of the gross tonnage and it is requested by the owners, the 175 percent rule which is more advantageous than the 32 percent in this case may be used.

MEASUREMENT OF ENGINE ROOM

In referring to the engine room, it is understood to be that space occupied by the engine room itself and boiler room together with the spaces strictly required for the workings of the engines and boilers, the space below the crown of the engine room. In this connection the crown or top of the main space of the actual engine room from which the depth of same is to be taken will either be at the under side of a deck or if the side bulkheads are curved, at the point or height at which the curve terminates; and the contents of the shaft alley, alleys or trunks in screw vessels including the escape trunk leading from the after part of the shaft alley to the deck, provided that it is not larger than necessary for the

purpose of an escape from the shaft alley to the topsides.

The length of the engine room extends from the bulkhead just forward of the fireroom to the one aft of the engines, provided that space is not in excess of that required for the actual operation of the engines and boilers. In case this exceeds the space required, only the space actually required for this operation is allowed. In addition to this, engineer storerooms, tool rooms and dynamo plants, when situated in the engine room and not partitioned off by watertight partitions are included in the engine room space. It is, therefore, advisable to partition these parts off with plates half-way up, the remaining distance being enclosed with heavy wire screening.

ADVANTAGE ENJOYED BY OIL BURNERS

Due to a recent decision of the Commissioner of Navigation in which he directed that all double bottoms of the cellular type be exempted from measurement: It has given the oil burning vessel considerable advantage over the coal burning ones, due to the fact that they can carry their fuel in their double bottoms which are not included in the gross tonnage. They also have their settling tanks included as a portion of the engine room, thereby, when necessary, increasing this space just sufficiently to slightly exceed the 13 percent of the gross tonnage, and so obtain an exemption of 19 percent of their cargo space, whereas in reality their bunker space is in their double bottoms which is not included in their tonnage.

The rules of measurement require that all spaces which are deductible must have, permanently cut in a beam and over the doorway of every such space the number of men it is allowed to accommodate or the purpose for which used, the following words: "Certified to accommodate — seamen," "certified messroom," "certified W. C.," etc.

It will be noted from the above that the words gross and net tonnage of a vessel have absolutely no meaning in connection with the size of the vessel, or the amount of cargo she can carry, but are merely a combination of figures which indicate the amount of attention that the owners pay to the exemptions in the law which has been enacted for their benefit.

When the statement was made at the beginning of this article, that an American ship pays more to transit our own American canal than a foreign vessel of the same size, it will be seen that this is due to the fact that the foreign shipbuilders and operators pay particular attention to the different parts of their vessel and that they obtain all exemptions and advantageous deductions, while the American ships do not, due to the fact that these spaces are not fitted in accordance with the rules. The result is that they throw up their hands as a certain very prominent steamship man did, and cried to Congress to change the laws in order to save the American merchant marine, whereas Congress has done everything in its power to help the ships. The only thing to do is for the steamship owners to familiarize themselves with the law and fit their ships accordingly to derive the benefits of existing laws and rulings.

Unfortunately it has been noted how little the American master knows of the tonnage rules in comparison with the masters of foreign vessels.

From the experiences related by various admeasurers in the prosecution of their duties, it would seem that in order to meet all degrees of competition, all parties, owners, masters of vessels and naval architects should familiarize themselves with the canal rules and incorporate the necessary changes in the vessel's hull, not with the purpose of evasion, but with the purpose of taking full advantage of the laws that are designed to benefit our merchant marine by wise exemptions. The foregoing paragraphs indicate in a measure how this can be done and it is hoped that some steamship companies will benefit by it accordingly.

S. S. Minnewaska—the First of the New Atlantic Transport “Minne” Boats

New Atlantic Transport Passenger Liner Minnewaska

**First of the New “Minne” Steamers Renews Direct
Passenger Service Between New York and London**

THE new Atlantic Transport liner *Minnewaska*, which recently completed her maiden voyage from London to New York, is a fine example of post-war shipbuilding. Designed and constructed at the yard of Harlan & Wolff, Ltd., at Belfast, Ireland, she is the largest vessel launched at that famous shipbuilding center since the war and is the largest vessel plying to the port of London. She will be followed early next year by a sister ship, the *Minnetonka*.

ORIGINAL “MINNE” SHIPS

Since losing its four original “Minne” boats in the war—all were sent down by mines or torpedoes while serving as transports—the Atlantic Transport Line has maintained a large and regular service for freight between American and British ports. The original “Minne” ships were vessels of about 14,000 tons register. The new ships are some 7,000 tons larger than the old and as a matter of course more elaborately fitted.

CARRIES FIRST-CLASS PASSENGERS ONLY

Great care was exercised in designing and building a ship that should meet every established requirement of the Atlantic Transport Line—large cargo capacity combined with high-class accommodation for first-cabin passengers only being chief essentials.

Following traditional practice, proven sound in the earlier ships of the “Minne” class, generous breadth was decided on, to give steadiness at sea. The design called for a big-bodied ship, therefore, having nothing of the express type about her, yet capable of good speed.

GREAT BEAM INSURES STEADINESS

In order to secure great steadiness at sea, the new liner has been given a greater breadth in proportion to her length than any other liner—80.37 feet to an overall length of 626 feet. Having a cargo capacity of 17,000 tons, and being fitted with bilge keels, the *Minnewaska* with her generous beam is one of the steadiest ships afloat.

Another outstanding feature of the new ship is the amount of space available to each passenger, which exceeds that on any other ship, owing to the fact that the passenger list is restricted to 369 persons, while the cubic contents of passenger accommodation, and the area of the ship’s decks, are on a scale that would afford generous space to a much greater number.

The following are the main particulars of the vessel:

Length overall	626	feet
Length between perpendiculars	600.8	feet
Beam, molded	80.37	feet
Depth	49.4	feet
Gross Tonnage	21,400	
Deadweight tonnage	17,000	
Horsepower	15,000	
Designed speed	17	knots
Trial speed	17.8	knots
Number of first class passengers	369	

PASSENGER ACCOMMODATIONS

All passenger quarters are amidship, and above the upper deck D. There are four decks devoted exclusively to passenger accommodations.

One deck, A, is given over entirely to public rooms which are of generous size and reflect an atmosphere of dignity. Fine natural wood panelings and white walls are the keynote of the principal decorations. The lounge is finished in American sycamore, in seventeenth century style; the reading-room in white; the smoking-room in paneled cedar; entrance halls in oak; the dining saloon—seating 322 persons at small tables—and the adjoining reception room in white and oak. In the reception room is a concert organ, a grand piano and a parquet floor for dancing.

Staterooms are designed to give large space to each passenger. Each principal stateroom has a bedstead, and some two, of either mahogany or oak.

B deck is occupied principally by suites and the larger staterooms. There are two suites here consisting of sitting-room, bedroom and bath, and ten semi-suites, consisting of

Promenade Deck

bedroom with bath, besides various connecting bedrooms. There are thirty-nine baths altogether, and all bedrooms have running hot and cold fresh water, steam heat, and direct and indirect ventilation. All B deck rooms have rectangular windows, as in a house.

The service section of the ship is designed to embody many modern features, including a complete electrical bakery, and electric kitchen equipment.

PROPELLING MACHINERY

Propulsion is by a two-shaft arrangement of Brown-Curtis single reduction geared turbines with an astern tur-

Reading Room

bine incorporated in the exhaust casing of each low-pressure turbine.

Steam is generated at 215 pounds per square inch and with a superheat of 100 degrees F. in 12 watertube boilers, which are arranged for oil burning under the White low pressure system, working under assisted natural draft.

AUXILIARIES ELECTRICALLY DRIVEN

The electrical installation is very extensive. All winches are electrically driven as are nearly all the engine room auxiliaries. There are four 400 kilowatt direct current generators, each coupled direct to a steam turbine. The dynamos run in parallel and are each capable of giving an output of 1,818 amperes at 220 volts. In addition there is one 75 kilowatt dynamo direct coupled to a Burmeister & Wain Diesel oil engine, situated at the stern for supplying current if for any reason the main dynamos are out of action.

The electrically driven engine room auxiliaries include the main circulating pumps, of which there are four, each of 120 brake horsepower, sanitary pump, forced lubricating pumps, air and circulating pumps for the auxiliary condenser, forced draft fans and bilge pumps. In all, 20 electrically driven ventilating fans are fitted.

Oil-Fired Scotch Boiler Gives 85 Percent Efficiency*

By C. J. Jefferson**

Tests by United States Shipping Board and Bureau of Mines show that combined efficiencies of Scotch boiler, superheater and air heater of 85 percent can be obtained with oil-firing and forced draft, 83 percent with oil-firing and induced draft and 78 percent with hand-firing, coal-burning and forced draft.

THE following brief account of the tests run on a Scotch marine boiler by the United States Shipping Board in conjunction with the Bureau of Mines has been written with the idea of presenting to the marine world a few facts and figures in regard to the possible efficiencies and capacities that may be obtained with the Scotch marine boiler, provided

The first essential in obtaining higher efficiencies is to educate the operating personnel to the point where they appreciate what higher efficiencies mean, how to use the instruments necessary for determining the efficiency of combustion, and how to correct faulty combustion and thereby build up boiler efficiency.

For this purpose the United States Navy has now opened a school at the Philadelphia Navy Yard for the benefit of the United States merchant marine, where a short and intensive course is given in the theory and practice of fuel-oil burning. Candidates for this school must be American citizens holding merchant marine licenses with the grade of second assistant or higher.

The tests which are outlined below were conducted by the United States Shipping Board in order that reliable and accurate data might be obtained as to the possible efficiency and capacity of the Scotch marine boiler, which is one of the oldest types of boilers in service and which has been accepted as a good, reliable servant without due regard being paid to its possible efficiency.

The Bureau of Mines was especially interested in making the thermodynamic survey of the boiler by means of thermocouple readings, gas analyses, etc., to determine the effects of combustion by the water-cooled furnace.

it is operated with the same care in supervision as that given to the average efficient stationary plant.

From the analysis of the logs of approximately 250 vessels, it is apparent that the average merchant marine cargo carrier develops approximately 60 to 65 percent efficiency in her boiler plant when oil-fired and that these values are from 55 to 60 percent for coal-fired boilers. This same condition holds true for the average stationary plant of less than 1,000 boiler horsepower, as has been shown by several analyses made at various times of boiler tests conducted on this type of plant.

The time has come, however, when better results must be obtained. The Diesel engine is rapidly entering the marine field and the steam-driven vessel must develop its maximum efficiency, if it hopes to be able to sail in competition with the motorship, even after making all allowances for the relative difference in the first cost for installation.

Moreover, the merchant marine of the United States has established a higher standard of living for its operating personnel than its competitors. This higher standard means increased cost of operation, which, in turn, must be met by increased efficiency of performance.

*Abstract of paper read before Metropolitan Section of the American Society of Mechanical Engineers, New York, November 14, 1922.

**Head of Fuel Conservation Section, United States Shipping Board.

Fig. 1.—General Arrangement of Scotch Marine Boiler Tested

Fig. 2.—Superheater Used with Scotch Marine Boiler Tested

Its findings are now being prepared by Mr. Mumford of the Bureau of Mines and his associates who worked with him and the author in carrying out these tests.

The boiler selected for the test purposes was a single-ended, three-furnace, separate-combustion-chamber type, hav-

ing 2,777 square feet of heating surface with coal fire and 3,022 square feet with oil fire. The boiler was fitted with a Foster waste-heat superheater having 774 square feet of heating surface and which was placed within the gas pass above the smokebox. Above this superheater was an air heater having 1,220 square feet of heating surface which heated the air supply to the Howden fronts when running forced draft. Fig. 1 shows the general arrangement of the boiler and Fig. 2 that of the superheater.

THE TESTS

Tests were divided into four distinct groups, namely, hand-fired coal, pulverized coal, forced-draft oil fire, and induced-draft oil fire. The pulverized-coal experiments were conducted to the point where it was demonstrated that this type of firing is not feasible for marine service of the Scotch boiler, as the limited size and water-cooled feature of the furnaces and combustion chambers prevented operating at ratings which were sufficiently high to meet the demand made by the average marine boiler plant.

Fig. 3 shows the boiler fitted for the hand-fired coal-burning test. In this figure the smokebox, ashpit, and fire doors

are shown wide open as it was taken immediately after thorough cleaning of the fire side of the boiler in preparation for the test. Four of the coal-burning tests which show typical results are given in Table 1. These tests are selected as representing results covering a combustion range from 13.07 pounds to 30.9 pounds of coal per hour per square foot of grate surface. It will be noted that the plant efficiency including boiler, superheater, and air heater ranges from 73.9 to 77.9 percent. All of these tests were run under forced-draft operating conditions.

The forced-draft oil-burning tests were conducted using Dahl, Schutte & Koerting, Coen, Todd, and Bethlehem Shipbuilding Corporation burners, all of these except the last named being used in conjunction with the Howden combined oil- and coal-burning front.

FORCED-DRAFT RUNS

Fig. 4 shows the boiler fitted with burners installed in the Howden front for forced-draft runs. Table 2 gives the results for three representative tests of this series covering a range of from 0.276 to 0.666 pound of oil per hour per square foot of heating surface. It will be noted that the combined boiler, superheater and air heater efficiency ranges from 83.5 to 84.6 percent. Fig. 7 gives the average efficiency values covering the entire series of forced-draft oil-burning tests.

Fig. 3.—Scotch Marine Boiler as Fitted for Hand-Fired Coal-Burning Test

The induced-draft tests were conducted with the Bethlehem Shipbuilding Corporation burner shown in Fig. 5, as well as with the Schutte & Koerting types "L" (modified) and "N," the Coen, the Todd, and the Enco burners. This latter burner, Fig. 6, was originated at the Philadelphia Navy Yard Fuel Oil Test Plant, and its adaptation for use in Scotch boiler service was developed during these tests.

INDUCED-DRAFT TESTS

The ratings obtained in these induced-draft tests were limited by the amount of available draft as the height of stack above the center of furnace was only 40 feet and this draft was augmented by a 1/2-inch steam nozzle. The combined effect of the stack and nozzle produced an 0.9-inch draft at the base of the stack. Table 3 gives the data of four representative tests covering a range of from 0.233 to

Efficiency of boiler without superheater, percent	82.35	78.98	79.29	78.70
Smoke, Ringelmann scale	1.5	1.75	1.5	2.5
Heat balance:				
Heat absorbed by boiler and superheater, percent	82.9	80.2	81.1	80.6
Loss due to moisture in fuel, percent	0	0	0	0
Loss due to burning hydrogen in fuel, percent	5.7	5.7	6.0	6.1
Loss due to heat carried away in dry gas, percent	7.1	8.4	9.6	9.4
Loss due to CO, percent	0.1	0.6	0	0.2
Loss in unconsumed oil and unaccounted for, percent	4.2	5.1	3.3	3.7
Heat in fuel as fired, percent	100	100	100	100

0.513 pound of oil per hour per square foot of heating surface and showing efficiencies ranging from 80.6 to 82.9 percent. Fig. 8 gives the average efficiency values obtained from all of the tests of this class.

SUMMARY

In comparing Figs. 7 and 8, the fact must be kept in mind

Fig. 5.—Scotch Marine Boiler as Fitted with Bethlehem Burners for Induced-Draft Tests

Fig. 6.—Scotch Marine Boiler as Fitted with Enco Burners for Induced-Draft Tests

that the induced-draft tests did not have the help of the air heater in building up furnace efficiency.

From the foregoing data it will be seen that the Scotch marine boiler is capable of efficiencies considerably in excess of the average operating values obtained, and it is, therefore, a matter of simple calculation to show what considerable fuel savings are possible when reasonable supervision is shown on the part of the operating force.

Fig. 7.—Average Combined Efficiency Values Obtained in the Forced-Draft Oil-Burning Tests

(1,002.46 × pounds oil per square foot of heating surface = oil per burner.)

Fig. 8.—Average Combined Efficiency Values Obtained in the Induced-Draft Tests

(1,002.46 × pounds oil per square foot of heating surface = oil per burner.)

[EDITOR'S NOTE.—Photographs of all the burners used in the tests were submitted to the American Society of Mechanical Engineers with the original paper. The selection of illustrations was made by the editor of *Mechanical Engineering*, in which the paper was first published and from which the above abstract is reprinted.]

Improved Scavenging Two Cycle Oil Engine

TWO cycle Diesel engines, ranging upwards from 50 horsepower to any power required, or from 4-inch cylinder bore, have been developed by the Knudsen Motor Corporation, 30 Church street, New York, claiming as their greatest feature practically 100 percent scavenging efficiency. The Knudsen engine is designed for either electric or direct drive and has an extremely light weight per horsepower.

It is claimed that the high fuel economy and mechanical efficiency are obtained by the elimination of all but four mechanical motions. The fuel pump is operated by a cam and the fuel valve is automatically actuated by the impulse of the fuel pump. The crank shaft is operated by the connecting rod which in turn is moved by the piston. Air in the cylinder when expanding gives an impulse to the piston. A long period of expansion is obtained, due to the short exhaust ports which are 10 percent of the stroke. From this it will be understood that all exhaust and scavenging valves and complicated casings have been eliminated. The thorough scavenging effect combined with the design of the cylinders produces the necessary mixing of the pure air charge within the cylinders and accomplishes complete combustion.

PISTON CONTROLLED PORTS

The pistons are arranged so that the one controlling the exhaust ports uncovers them before the scavenging ports there-

Knudsen Engine Erected for Shop Tests

by allowing the exhaust gases to escape to the atmosphere and lowering the pressure to atmospheric thus precluding the possibility of the exhaust gases blowing back into the scavenging system. The pistons working up and down at the same time control the period of the exhaust as well as the scavenging period. The early opening of the exhaust ports is accomplished by advancing the right side piston a certain number of degrees ahead of the left side piston which controls the opening and closing of the scavenging ports. The earlier opening of the exhaust ports results in their earlier closing, thus permitting the cylinders to become charged with pure scavenging air at scavenging pressure after thorough scavenging takes place and before compression commences. This results in what is termed super-charging, the ad-

Cross Section of Engine Showing Arrangement of Cylinders and Ports

vantage being that greater expansion takes place while consuming the same amount of fuel, with the result that higher economy and more complete fuel combustion are obtained. Super-charging varies with different speeds and powers—varying from 10 to 30 percent for the greater speeds and higher powers.

METHOD OF SCAVENGING

Thorough scavenging is secured in the Knudsen motor by introducing two-thirds of the volume of scavenging air into the cylinders through ports circumferentially arranged upon the cylinder walls. One-third of the air is passed through the piston heads to act as a cooling agent for the pistons. This air absorbs a certain quantity of heat in moving through the pistons which increases its volume as well as its velocity, after which it finally passes into the cylinder through the circumferential ports to assist the larger amount of air blowing through the scavenging ports and to complete the expulsion of burnt gases.

Supercharging.

Compression fuel valve open for injection.

Working stroke.

Diagram of Scavenging and Supercharging of Knudsen Motor

The scavenging pump which supplies the air at 2 to 3 pounds gage pressure for scavenging the working cylinders is so designed that a ratio of $1\frac{1}{2}$ to 1 exists between its cylinder volume and that of the working cylinders, thus insuring a sufficient quantity of air even at low speeds to perform its function.

AIR-COOLED PISTON

The pistons are cooled as noted above by passing a third of the volume of scavenging air through them, thus eliminating the usual method of piston cooling by means of water or oil carried to the pistons by telescopic pipes. Water especially in most engines is a constant source of trouble since there is always danger of its entering the lubricating oil systems; the greatest care must be maintained on the part of the operators to prevent this leakage.

Crank shafts are made to pass the highest requirements and are both statically and dynamically balanced in order to reduce vibration. With the exception of the spray valves, there are no valves necessary for the intake of air or the exhaust of burnt gases so that cam shafts, valves and their openings and closing gear and springs are eliminated.

Fuel is injected to the cylinders through the spray valves by a multiple plunger pump cam-actuated. The amount of fuel supply to each cylinder is controlled by this pump under a pressure of 100 pounds. The pump also acts as a measuring device to regulate the amount of fuel for each cylinder. The pump control is arranged so that the injection of fuel can be retarded or advanced while the engine is in service.

TYPES OF DRIVE

The engine can be geared down to the most economical propeller speed by means of a quill type floating pinion and gear. The pinions are made of the finest chrome nickel steel, a material which has proved to be excellent for marine service. The pinion acts in such a way that the teeth of the gear are covered by the necessary film of oil when working which prevents direct metallic contact between the teeth of the pinion and gear thus insuring long life.

Westinghouse Company Develops Automatic Sectional Type Electric Bake Ovens for Marine Use

A NEW type of electric bake oven that, because of its economy, flexibility, and compactness and the high quality of its product is particularly well adapted for marine service has recently been developed by the Westinghouse Electric & Manufacturing Company. This new oven, which is known as the automatic sectional-type electric bake oven, is constructed in sections, each of which is independent of other sections and is entirely automatic in its operation.

The sections are made in two standard sizes, one with a capacity of 20 and the other of 60 loaves.

Each section is equipped with motor operated snap switches, a thermometer and a thermostat for controlling the oven temperature. The heating units, which are entirely enclosed, are mounted at the top and bottom of each section and are distributed so as to give a uniform temperature throughout the baking chamber.

The temperature of these ovens is controlled by an arm projecting through the metal control box at one end of each section. By moving this arm along a graduated scale, oven temperatures ranging from 300 to 500 degrees F. can be obtained. When the temperature in the oven section gets

Battery of Westinghouse Sectional Type Bake Ovens, Each of Which Consists of Two 60-Loaf Sections

too high, the thermostat, operating through the motor operated snap switch shuts off the current automatically and turns it on again when the temperature has dropped. It is thus possible, it is claimed to keep the temperature within ten degrees of the operating temperature without any attention whatever.

Because of the independence of the sections and the efficiency of the insulation between them, different temperatures can be maintained in each section and a number of products, limited only by the number of sections in the installation, can be baked at one time. A new section can be added to the installation at any time, if the need arises.

United States Battleship Colorado

(Continued from page 608)

are of sufficient capacity to open the circuits under full power and full voltage, although in normal operation, the circuit breakers are never opened or closed under load. The levers for manual operation of the circuit breakers are located directly in front of the control room instrument board, and are connected to the circuit breaker operating mechanisms through a system of bell cranks and rods. The arrangement of the operating levers is such that the operator faces forward. The operating levers are interlocked to prevent improper operation. The primary circuit breakers are located in the control room and are arranged in two rows athwartship with an aisle between them for inspection and repair. The secondary short circuiting breakers are located in the motor rooms and are operated from the control room. The liquid rheostats for controlling the motor secondaries are located in the control room. In order to disconnect circuits completely, self-contained disconnecting devices have been provided on the reverser and generator circuit breakers. The mechanism is so arranged that the circuit breaker must be opened before it is possible to disengage the disconnecting device. This provision safeguards the men in case of improper or faulty operation, and at the same time makes it possible to inspect or repair a circuit breaker while the ship is under way.

The levers operate the circuit breakers and rheostat valves in pairs, and are arranged in a single row, directly aft of the circuit breaker structure. The arrangement is symmetrical so that levers on the left of the central position operate the circuit breakers in the after generator and port motor circuits; while those on the right of the central position operate the circuit breakers which control the circuits of the forward generator and starboard motors. All the levers are mechanically interlocked so as to insure the proper sequence of operation. The scheme of interlocking is such that the field must be off and the steam control reduced to a low setting before any of the above circuit breakers can be operated.

With two generators in operation, the control of the port and of the starboard side of the ship are independent. With the tie circuit breaker closed, and one generator in operation, the direction of rotation of port and starboard screws may be in the same or opposite directions, but of necessity must be at equal speeds.

All starting and maneuvering is done with the 24 pole connection. When the motors are thus connected, the secondaries are controlled during starting and reversing by means of liquid rheostats. There is one double rheostat for the port motors and one for the starboard motors. The rheostat consists essentially of a two-compartment tank, the lower compartment of which serves as a reservoir for the electrolyte, and also as a container for the cooling coils, while the upper compartment contains the electrodes. When it is desired to use a rheostat, the valve in the upper compartment is closed by means of a lever operated from the control stand, thus allowing the liquid to rise in the upper compartment. After the maximum level has been reached, the motor secondary is completely short-circuited by means of an oil circuit breaker which is operated by a lever from the control stand.

The generator field excitation is adjusted by means of a field lever in the control room, which controls the generator field of a motor generator booster set. The booster generator is connected in series with the generator field and functions to either boost or buck the 240 volts supplied by the auxiliary generator which furnishes excitation and auxiliary power. With this arrangement, the required value of generator field excitation is obtained most economically.

The protection for the propelling machinery is provided by a ground detector system, which automatically indicates a ground and also the circuit in which the ground exists, and by unbalanced phase relays which are arranged to trip out the generator field switch in case of any appreciable unbalance in the loadings of the different phases, which might be caused by grounds, short circuits, or otherwise.

SAN FRANCISCO PORT RECORDS BROKEN DURING JULY.—With a total of 1,198 vessels passing through the port of San Francisco during July, all records were broken. There was more activity along the San Francisco water front during that period than for any similar period in the history of the port. Of the total number of vessels passing through the port 616 were arrivals and 582 departed. The 616 arriving ships represented 1,432,819 tons while the 582 departing vessels represented 1,306,416 tons, or a grand total cargo of 2,739,235 tons. The enormity of the gains in commerce, with its resultant prosperity, is vividly shown by a comparison with the figures of July, 1922. In that month the arriving ships numbered 499, showing an increase in favor of July this year of 117 ships. The departing ships in July, 1922, numbered 478, a gain of 104. In tonnage, the July, 1922 arrivals aggregated 1,021,537 tons showing an increase for the past July of 411,282 tons over the same month a year ago. The departing tonnage for July, 1922, was 999,602 tons, showing an increase for July, 1923, over the corresponding month of the previous year of 306,814 tons.

Surplus Tonnage Problem Confronts Great Britain

Scheme for Disposal of Obsolete Ships Unfavorably Received—British Banks Suffer from Shipping Ventures—Imperial Economic Conference

By a Special London Correspondent

ONE of the most interesting exchanges of views in recent times is taking place in United Kingdom shipping circles on the subject of excess tonnage. It has been put forward that the British Government should make an annual grant of about two and a half millions sterling to provide for the total extinction each year of a million tons of obsolete merchant ships. A process of gradual extermination, spread over a period of four years, is the policy advocated.

The beneficial effect of withdrawing, by degrees, some four million tons gross of "obsolete, uneconomical vessels" from maritime service is regarded by the shipping man responsible for the suggestion as "inestimable." Freights, he states, would be assisted to a profitable level, large sums of money wasted upon costly repairs and renewals to worn-out "Methuselahs" of the mercantile fleet would be saved and set aside, and, to quote, "with the advent of a steady all-round improved shipping position, the production of new tonnage would be warranted, and our shipbuilders and engineers would no longer be among the ranks of the unemployed. And, if Great Britain's useful lead were followed by an international movement towards the same desirable end, so much the better for shipping and the world at large."

GOVERNMENT MEDDLING OPPOSED

And so much for the scheme in outline. Frankly, however, it is not meeting with anything like a large measure of sympathy. Its opponents are, in fact, numerous, and decided in their published and unpublished views. Even were Government approval of the plan forthcoming (and this, in the present condition of State engagements and commitments, is regarded as next to impossible) it is felt that to invite the Government to take a "hand" in the conduct of the shipping industry would be asking for trouble. The originator of the scheme gibes at the opposition's fear of the "spectral but affrighting head" of the ghost of Government interference. Yet the danger is none the less real, and for his reason, apart from all others, the plan is scarcely likely to be adopted.

But perhaps the most telling argument against the adoption of the proposal is that shipping people are dead against the institution of artificial measures in endeavoring to remedy the surplus tonnage problem. They hold the view that economic alleviation is only to be found in taking advantage of natural expedients. Curiously enough, the interests whom the scheme is primarily intended to benefit are opposed to the "subsidy" suggestion. One leading builder does not think there is anything in the plan particularly attractive to shipbuilders as a sound economic proposition. If, he says, these millions of tons of vessels are obsolete in the fullest sense of the word, then they may as well be, for practical purposes, deducted from the statistics. As to subsidies, he does not consider that, either for themselves or other industries, shipbuilders will favor the principle.

Ship repairers are not enamored of the proposal—some, indeed, view it with grave doubts. One authority points out that a principal source of employment for ship repairers' workers and their plants is the survey work, which increases with the length of life of the ships. Moreover, this expert fears that shipbreaking, always a speciality and largely carried out on the continent, would prove a poor substitute for

this department of their services, the repairs necessary to maintain old ships in a seaworthy and efficient state.

AMERICAN PROPOSAL CONSIDERED IMPRACTICAL

Plans to rectify the international shipping position, however, are not confined to this side of the Atlantic, and in this regard interest is being displayed here in the New York proposal that there should be a plan of co-operation between American and foreign steamship owners as a remedy for the world's shipping ills. Under this scheme, American and foreign owners would each furnish one-half the tonnage required to move the freight over a particular route, each acting as loading agent for the other, and the ships of each working on an alternative schedule. While the plan would benefit at all events some interests, British shipping people regard it as unworkable, for the reason that no agreement could be come to which restricted the trade to specified vessels at, presumably, specified rates. The originators of the scheme would seem to have made provision for damping the enterprise of any "tramps" which might, consciously or unconsciously, make their appearance where least wanted, but there are reasons for stating that, whatever may be arranged between the principal lines, the tramp would at one stage be bound to enter, incidentally wrecking the agreeing lines' calculations. Furthermore, it is considered that there would have to be a very substantial inducement before British shipowners would agree to exclude all British vessels from trading between America and the East and to the Continent.

ENGLISH BANKS HARD HIT BY SHIPPING LOANS

One phase of the shipping position which is becoming more and more clear as the months go by is the part the great banks have played, both during the boom that is past and the slump that is still in evidence. Practically every one of the great banking institutions in England—concerns admittedly expert in regard to general finance, but completely "at sea" where shipping subjects were in question—engaged during the good times in lending fabulous sums of money on vessels which in normal times would realize only a tithe of their boom-time "values." These banks, almost without exception, are now paying very dearly for their inexperience and their excessive indulgence in matters maritime.

But they are clinging to the boats which fate, in the guise of shipwrecked steamship companies, has thrown on their hands. Shipping experts regard this as a foolish policy and condemn the banks, firstly, for advancing tremendous amounts to "mushroom" shipping concerns, and, secondly, for not clearing out of shipping the moment it became evident that the market was going to smash. The banks, however, are most reluctant to relinquish the vessels on which they lent so much money, and, it would seem, intend to hold them indefinitely in the hope of better times.

Meanwhile, an uncomfortably large number of steamship companies are operating on a hand-to-mouth basis; in some cases managers are still running their boats, but they are only enabled to do so in consequence of the indulgence of the mortgagees in refraining from foreclosing and in permitting the managers to continue working on condition that they finance the voyages. Then again, in notable instances, if the income tax authorities exercised their undoubted rights,

and pressed for payment of the large sums outstanding under this head, there are companies which would be bound to smash.

Incidentally, it would seem that a Norwegian bank has its own little way of getting over the mortgage difficulty, for it is understood to have taken over the steamers, formed them into a company, and placed a friend—presumably a shipping man—in the position of manager.

EXCESSIVE PORT CHARGES IN AUSTRALIA A SERIOUS OBSTACLE

The Chamber of Shipping of the United Kingdom is adopting a strong attitude on the subject of port charges, notably in Australia and New Zealand, where the costs are considered to be out of all proportion. The chamber has observed the continuance of high port charges, light dues, pilotage rates, quarantine expenses, and other terminal costs in Australian ports, "at rates which are far in excess of anything obtaining in this country," and urges upon the Federal and State Governments that such charges constitute a serious obstacle to the free development of Australian trade. Further, it is pointed out that, in respect of all similar charges in the United Kingdom, drastic reductions have been made, so that, speaking generally, charges do not now exceed 40 to 50 percent above pre-war. The instance is cited of an 11,000-ton cargo steamer which, making a stay of five days in port, pays 55 to 62 percent more in dues in the United Kingdom than in 1913, 58 percent more in South Africa, but in Australia 148 percent more. In this connection it may be of interest to note that the dock dues and charges in the principal United Kingdom ports compare as follows with the last pre-war year:

Port	In excess of 1913, Percent
London	47.50
Liverpool	72.00
Glasgow	58.33
Newcastle	70.00
South Wales ports	60.00
Southampton	66.66
Hull and North-East Coast ports.....	75.00

Eighteen months ago these charges stood at 150 percent above pre-war, but then the shipping and commercial organizations got busy and induced the port authorities to fall into line with declining costs. The people principally concerned fail to see why Australia cannot do the same.

Another leading subject in regard to which the Chamber of Shipping is showing the liveliest interest is in connection with the taxation of shipping profits abroad. The chamber's efforts to induce the Government to introduce legislation with a view to adopting the United States proposal in regard to the exemption of shipping from taxation on a reciprocal basis having met with success, the chamber is now engaged in urging the authorities on this side to do all in their power to persuade all the leading maritime nations to enter into a similar reciprocal arrangement.

SHIPPING PROBLEMS TO BE DISCUSSED AT ECONOMIC CONFERENCE

As all the world knows, the Imperial Economic Conference is scheduled to be held in London in October this year, and it is satisfactory to note that the future of the shipping industry is to find a prominent place in the weighty deliberations which the conference will doubtless produce. So many things may happen before these lines see print that it would be futile to anticipate to any great extent the probable outcome of the conference. But that is no reason for withholding from placing on record what representative British shipping interests have done, and are doing, in the light of the forthcoming conference.

When Sir Ernest Glover, the President of the Chamber

of Shipping, was appointed as a member of the Board of Trade Advisory Committee in connection with the conference, a special committee was appointed by the shipping industry, representative jointly of the Chamber of Shipping and its scarcely less eminent "colleague," the Liverpool Steamship Owners' Association, with the primary object of framing a statement of the views of the industry upon the subjects which it seemed probable would be discussed at the conference. The committee has now embodied its views in a lengthy statement in the course of which it is reiterated that Government enterprises should be put on an equal footing with private enterprises in all respects—for example, taxation, liability and equality of opportunity—and that the Government of the Empire should be urged to abandon all shipping ventures. State ownership the committee is convinced is injurious to private enterprise and involves either a burden on the taxpayer or higher freights and less efficient services and is a constant cause of international discord.

DISCRIMINATION

As to discrimination, the committee maintains that the effective resistance of Great Britain to attempts by foreign countries to impose restrictive and discriminatory measures upon British shipping is limited by the extent to which the Dominions will co-operate with her. A United British Empire, it is felt, could compel discriminating countries to give equal opportunity to British shipping and that under their own or other flags, and it is suggested that the Imperial Economic Conference should agree that all parts of the Empire should stand and act together to secure this.

In regard to air communications the committee is refreshingly brief. Shipping, it says, should be left to itself to deal with the competition of air services. The help given by the State to air services should be only such as is necessary in the national interest.

FINANCIAL DIFFICULTIES OF PROMINENT SHIPYARD

The position of the shipbuilding industry of the British Isles may be best summed up in a review of the unfortunate financial affairs of one of the leading companies—Messrs Workman, Clark and Company, Ltd., of Belfast—as revealed by an official investigation.

To go back to the beginning, rumors circulated that the company would be unable to meet its debenture interest obligations at the fixed date, and, in consequence, the Stock Exchange quotation of the debentures experienced a huge slump. However, the interest was paid on the day on which it fell due, but it transpires that the company was only able to disburse the necessary sum following the sale of a portion of its holding in other companies. Moreover, the sinking fund instalment due on June 1 has not been paid owing to the fact that the company has insufficient cash available. To add to the trouble, it is now made clear that the Northumberland Shipbuilding Company, Ltd., of Howdon-on-Tyne, which owns the whole of the Workman Clark shares, and which had guaranteed the interest on the Workman-Clark debentures, is unable, owing to financial reasons, to fulfill its obligations.

It was, of course, generally appreciated that, due to the abnormal depression in the shipbuilding industry, companies carrying on this class of business must be having a pretty poor time, but the revelation that, so far as the two companies named are concerned, the situation is worse than was anticipated, caused an unpleasant shock in the shipping and shipbuilding world. What the future holds for either of the companies is, at this writing, not yet clear, but, in regard to Workman, Clark and Company, one point on which there is no doubt is that two or three hundreds of thousands of pounds sterling of new money must be provided if the company is to clear itself of more pressing obligations, and still have capital in hand with which to carry on.

Sketch Showing How the New D. & C. Passenger Steamship Greater Detroit Will Look When Completed

Largest Great Lakes Passenger Steamer Launched

Vessel Is First of Two Sister Ships for D & C Navigation Company and Is First Passenger Steamer Launched on the Lakes Since the War

WITH the launching of the first of the two new steamships of the D & C Navigation Company at Lorain, Ohio, on September 15, the first authentic details of the largest inland waterway steamers in the world were made public by A. A. Schantz, president and general manager of the company. The second of the sister ships will be ready for launching in about three months.

The hulls of these two sister steamships were built by the American Ship Building Company of Lorain, Ohio, and when completed they will compare with many of the transatlantic steamships. Their design is the result of a life-long study by Frank E. Kirby, the noted authority on Great Lakes steamers. The total cost of each steamer will be about \$3,500,000.

The construction of these boats required unusual study to meet the conditions imposed by the high speed run between Detroit and Buffalo, the routes these vessels are to follow being complicated by shallow channels and the traversing of the entire length of Lake Erie. The trip is slightly more than 260 miles and it must be made day in and day out on schedule to meet certain trains. It was also necessary to construct the boats so that they would not only be "floating hotels" but would also carry a large number of automobiles and express freight.

In general, the design follows the conventional side wheel steamer characteristics, having a refined steel hull, carrying a great superstructure of wood supported by braces. It is interesting to note that these superstructure decks are each about three-quarters of an acre in area. The type of the stern is unusual, and has not been used before in this type of vessel, being of an unusual width.

PRINCIPAL DIMENSIONS

Length overall	550 feet
Beam, molded	58 feet
Beam, over guards	100 feet
Depth	23 feet 6 inches
Cargo capacity	1,000 tons
Number of passengers	about 1,200
Horsepower	10,000
Speed, miles per hour	21

Some idea of the exceptional size of the vessel may be gained from a statement of the number of rooms on the various decks. On the promenade deck there is a total of 205 rooms, including 12 parlors and baths; several others have shower baths. On the gallery deck there is a total of 254 rooms, including 12 parlors and bath rooms. On the upper deck there are 166 double berth rooms, and an entire boat has 650 rooms. The total number of passenger berths and beds number 1,200. In addition to this, there are, of course, a great many accessory rooms not only for the use of passengers, but also for housing and maintaining the crew, and for taking care of the demands of the passengers as well as for the operation of the vessel.

RUDDERS AT BOW AND STERN

For steering the vessel there are two rudders, one at the bow and the other at the stern. The rudder at the bow is necessary to facilitate the handling of the boat in narrow waters at each end of the run. The stern rudder is of the balanced type and is operated by twin independent steering engines acting direct on the quadrant. These steering gears are both controlled from the pilot house.

There are eleven watertight compartments in the length of the vessel, formed by steel watertight bulkheads extending from the keel to the main deck. The double bottom is sub-divided into sixteen watertight compartments.

Accommodations for the deck, engineers' and stewards' departments are on a steel deck both forward and aft of the machinery. The freight space is on the main deck forward and the lobby entrance, cafeteria and dining rooms are aft on the main deck, with the galley and pantry on the orlop deck. Passenger accommodations are on the promenade, gallery and upper decks.

WOOD WORK

In vessels of this type the wood work is a most important item, depending upon a combination of strength, durability, beauty and lightness. To secure these necessary qualities, the principal structure is built of white pine using the best

clear California redwood for decks and partitions and Oregon fir for other parts.

The following parts are finished in selected figured mahogany: Lobby, main stairs, dining room wainscot, serving stands, cashier's desk and screens, sideboards, hat racks, doors, windows, trim and blinds, purser's office, steward's office with their desks, ticket racks, doors, windows, blinds, berths and fittings; lunch room wainscot, promenade deck salon, including stairs, side cross passages, stanchions and balustrades around wells at gallery and upper decks.

The following parts are finished in walnut: Doors and trim in the main salon, including stairs, rails, balustrades at gallery and upper decks, stanchion and stringer casings. The smoking room will be paneled in maple.

The parlors which have a hardwood finish will be done in the following woods: Two of mahogany, two in white mahogany, one in white maple and one in satinwood. The scheme of paneling and decoration will be of different "periods" in the several suites.

The main lobby will be finished in the Spanish style, and have rubber tiled deck, while the dining room will be in the Colonial style of architecture. In the great central salon the Italian Renaissance style prevails.

PLUMBING

As all the rooms are fitted with running water and many with baths, the amount of plumbing work is very great. Water is carried in steel tanks of 36,000 gallons capacity and there are tanks for 8,000 gallons of sterilized water, which after being chilled is pumped to drinking fountains throughout the vessel. Sterilized water is piped to all wash basins and generally throughout the ship. The violet ray system is used for sterilizing.

HEATING AND VENTILATION

As the greater part of the operating season occurs during the heat of summer, the ventilating problem has received very careful attention. Sheet metal ducts lead fresh air to all inside rooms. Fans driven by motors are located on the main deck and drive the air through washers into the ventilation ducts which distribute it to all parts of the vessels.

To prevent as far as possible the heating of the air in the ship, a great deal of money is being spent on the installation of engine and boiler casings and the under side of decks and at other parts of the structure, so that heat will not be conducted to the passenger quarters.

Radiators have also been provided in the public rooms and a heating pipe is run through the outer row of rooms and wing passages in order that heat may be provided when necessary.

SAFETY APPLIANCES

The entire vessel has been provided with a sprinkler system. In case of fire, fire detectors alarm the watchman of a rise in temperature at any point. The under side of the promenade deck is covered with galvanized sheet steel and fire doors have been provided in the cargo quarters and passages leading to rooms, thus dividing the vessel into zones.

Every room is provided with a telephone connected to a central station in the lobby.

In addition to life rafts and floats, twelve metal lifeboats of 60-person capacity and one metal work boat are carried.

Light and power for various uses are provided by three 100-kilowatt turbo-generators located on the main deck.

PROPELLING MACHINERY

The power plant consists of three double end and six single end boilers of the ordinary Scotch marine type, supplying steam for a three-cylinder compound inclined engine, driving side paddle wheels. These engines will develop 10,000 horsepower, and have a piston stroke of 9 feet. The side wheels have a diameter of 32 feet 9 inches, each having 11 paddles 14 feet 10 inches long by 5 feet wide.

The steamer will carry a crew of 300, including officers, and the cargo capacity will be about 1,000 tons. The speed of the boat will be about 21 miles an hour.

There will be two electric elevators, one for serving the linen room and galley and another automatic one between the main deck and galley.

A complete wireless set will be installed in each steamer in a room with accommodations for two operators, and motion picture equipment will be set up on both steamers.

Diesel Auxiliary Yacht Hussar IV

(Continued from page 603)

a companionway to the poop deck. The forward deckhouse, located just forward of the mainmast, contains the quarters for the wireless operator as well as the wireless apparatus, and in addition a large and well equipped chart room, having a deck toilet. This deckhouse has also been skillfully used to provide companionways for the officers and crew, thus avoiding the use of unnecessary obstructions on the deck.

One unusual feature of this new craft is the navigating bridge which has been placed just forward of the foremast and from which the captain has at all times an opportunity for navigating the ship without in any way being interfered by or interfering with the comfort of the owner and his guests. This bridge is so placed and so constructed as in no way to be unsightly or to interfere with the proper handling of the vessel under sail.

ACCOMMODATIONS

The arrangement below decks is rather novel, this portion of the vessel being arranged as follows:

The companionway from the after deckhouse runs athwartships and lands just aft of the mizzenmast on the center line of the vessel, there being a fore and aft passageway slightly on the starboard side of the centerline. At the forward end of this passageway the dining room has been placed, which is roughly 16 feet by 21 feet 6 inches.

On the starboard side is a pantry communicating with the crew's quarters as well as with the dining room.

At the after end of the fore and aft passageway and under the poop deck are the owner's quarters, consisting of two large staterooms and two separate bathrooms. These rooms not only have light and ventilation through the air ports and overhead skylights, but in addition have ventilating ports at the forward end where the deck level changes to the raised poop, which will provide excellent ventilation under all conditions.

Forward of the owner's quarters are four large double guests' rooms, each having a separate bathroom. Each of the staterooms and bathrooms is well ventilated not only by air ports but by overhead skylights.

The accommodations for the officers and crew have been arranged so that each department of the ship is segregated by itself, provided with ample and comfortable quarters, all being so arranged as to avoid any unnecessary labor in the maintenance of the vessel and in the service of food both to owner and guests and to officers and crew.

In order to reduce the number of the crew to a minimum, every advantage has been taken of the use of auxiliaries which are electric and include not only a windlass but also electric deck winches for handling boats and for making sail. The *Hussar IV* is lighted by electricity throughout, and is supplied with electric fans in every part of the living space. Forced ventilation is provided for use at sea when air ports and skylights must be closed, and the quarters throughout are heated by hot water. Included in the auxiliaries is an ice-making machine and in addition to ample storage space there is a large chill room, the temperature of which is maintained at any desired point by the use of the refrigerating machinery.

Applications of Arc Welding to Ship Construction—IV

Comparison of Cost and Percentage of Saving Obtained by Using Welded Instead of Riveted Joints

By E. H. Ewertz*

THE Ewertz type of electric arc welded ship as designed and patented by the author offers many novel features and is a radical departure from any previous design. It was gotten up with the idea, if possible, of eliminating all rivets and the features of construction inherent to riveting; in other words, the design is only adapted to electric welding and the construction is such that riveting cannot be substituted for welding.

It is the author's belief that substituting welding for rivets in a structure designed for using either method is wrong as a basic principle. The results derived from welding in such a method are, at least, partially defeated.

All of the structural shapes such as angle bars, tee bars,

tion keelsons and side stringers are suitably placed which together with transverse floor plates and plate frames form the proper construction. Deck construction is similar to side plating, and the whole structure when suitably welded produces an ideal construction that is even superior to that which could be obtained if the vessel were cut out of one solid block, because the fibers of the various parts are flowing in the proper direction. Accompanying sketches give a clear idea of the detail of construction.

ADVANTAGES OF EWERTZ DESIGN

In this as in other designs described, fully half of the welding can be performed before parts are erected and prac-

Fig. 76.—Deck and Outboard Profile Plans Ewertz Type of Electric Arc Welded Vessel

zee bars, etc., were designed primarily for convenience in riveting. One flange of an angle bar is used simply as a means of fastening the other flange in its proper position. It is only the outstanding flange that gives stiffness and strength to the plate construction and the flange used for fastening by rivets is valuable only for furnishing the place for the rivets and it does not add to the strength of the structure.

With this in mind, all flanges needed in the riveted structure for fastening are omitted and, in place of angles or other shapes, plates or flat bars are used. To produce reinforcement in many places, flanged plates are used but, in such cases, the flange on the plate performs the service of a stiffener.

The outer shell in this design is formed of metal channels or flanged plates, extending from the bow to the stern which are fastened together with welded butts. The flanges project inward thereby forming longitudinal stiffeners. In addition,

tically all overhead welding is eliminated except that required for filling in. Omission of all holes for fastening and the use of flanged plates in place of plates with bar stiffeners make each section or part much lighter, which reduces the cost of material very substantially. This type of construction also produces a complete ship with relatively few joints, thereby reducing the number of feet of welding. While the details shown illustrate a seagoing barge, these details are just as applicable to any type of ship construction.

A test carried out on a model barge built on 1/12 scale, with all parts in correct proportion, embodying the design above referred to as well as features of a patent now pending covering certain modifications in construction of floors and framing shows a remarkable increase in carrying capacity over that possible in an ordinary design of barge with riveted joints. The test also demonstrated that this type of design gave the structure extraordinary strength which was sufficient as shown in Fig. 81 to carry a 400 percent overload without any marked deflection.

*General Manager, Moore Plant, Bethlehem Shipbuilding Corporation, Ltd., Elizabeth, N. J.

Fig. 77.—Midship Section, Ewertz Type of Electric Arc Welded Vessel

COST DATA

In the preceding pages we have tried to present to the designers and builders of ships what has been done in the past with electric arc welding as well as what might be done by this process, but in order further to assist in the work, we will now give data on the cost as well as on the strength of welded joints, and also a comparison of strength between the riveted and welded joint. Many books and papers have been published in connection with this subject, particularly pertaining to the strength of joints, and in addition to the statements made in this paper, further information on this subject may be obtained from publications in the bibliography which will be printed with the final installment of this article.

In a ship designed for all electric welding, estimates show a saving in weight of structural steel material of over 25 percent as compared with a similar design for a riveted ship. The hours of labor for hull construction show a reduction of over 20 percent. Modified designs, or designs where either riveting or welding can be used, while they clearly indicate a saving, show a saving that is naturally proportionately lower to that obtained in a ship designed for all electric welding.

Mr. Bonner gives some interesting figures in connection with the construction of a 1,200-ton oil barge built by the Tank Shipbuilding Company, Newburgh, N. Y., which are tabulated in the next column.

Major James Caldwell, in a paper read before the Society of Engineers and Shipbuilders in Scotland, with reference to the cross channel barge AC-1320 previously described, states: "In labor, 245 man hours were saved in the construction of this barge. More than 1,000 pounds of metal were saved by the substitution of welding for riveting and even greater economy will result when the design is modified to suit electric welded ship construction. Altogether, there were

Estimated Construction Cost of a 166-foot by 39-foot by 8-foot-8-inch Barge

Items	Riveted Design	Welded Design
Plate fitters	\$1,236.00	\$618.00
Punching and shearing.....	1,045.00	522.00
Countersinking and reaming.....	976.00	
Riveting	3,427.00	
Chipping and calking.....	523.00	265.00
Smithwork	557.00	275.00
Assembling	2,010.00	1,320.00
Electric power	382.00	95.00
Foreman	360.00	360.00
Plant		300.00
Superintendence		900.00
Rivets	780.00	
Liners	142.00	
Shed and shoring lumber		145.00
WELDING—Assembling and construct- ing, 51,300 feet single fillet—		
Welders.. 6,000 hours @ 60c... \$3,600		
Current... 6,000 x 5.		
30,000 K. W. H. @ 2½c..... 750		
Wire, 7,200 pounds @ 6½c..... 450		4,800.00
Incidentals		250.00
	\$11,438.00	\$9,850.00

7,000 lineal feet of welding on the barge and over 3,000 holes required filling-up when the service bolts were withdrawn. The total cost of welding was (based on normal exchange) \$1,462.86, comprising: Electrodes, \$865.08; electric current, \$296.46 and labor, \$301.32.

"The cost of assembling similar barges built in the same yard by the ordinary method of construction, including riveting, calking and drilling, was \$1,892.48, while in

Fig. 78.—Bulkhead Construction, Ewertz Type of Electric Arc Welded Vessel

Fig. 79.—Inboard Elevation of Side Construction, Ewertz Type of Electric Arc Welded Vessel

another yard, where 10 barges were built, the average cost was \$2,203.52."

Major Caldwell's proposed design of an all electric arc

Fig. 81.—Model of Ewertz Type of Electric Arc Welded Vessel Carrying 400 Percent Overload

Fig. 80.—Top View of Bottom Construction, Ewertz Type of Electric Arc Welded Vessel

welded 225-ton barge described previously requires the equivalent of 9,000 feet of continuous welding of 5/16-inch plating. Of this amount 4,000 feet can be performed in the field under the best possible conditions, leaving 5,000 feet to be welded after erection. Basing the speed of welding on that obtained in building the cross channel barge AC-1320 we have an average of 7 feet per hour per operator on 5/16-inch plating which is very conservative. We have from the above, 1,286 operator hours of total welding time which at 60 cents per hour represents \$771.60.

For power and electrodes, accurate figures have been worked up by the Alloy Welding Processes, Ltd., using their flux covered electrode, which show that the cost for 5/16-inch plating is 8.2 cents per foot or \$738.

The total cost of welding, therefore, is \$1,509.60 or 16.8 cents per foot of welding.

Fig. 82.—Model of Ewertz 400-Ton Electric Arc Welded Barge

RIVETING vs WELDING COSTS

Fig. 83.—Chart Showing Percentages of Saving Between the Use of Riveting and Welding

Major Caldwell states that, from reliable figures of riveted construction, he estimates that single riveted lap joints for a barge of similar design would cost 48.6 cents per foot of joint.

Mr. H. Jasper Cox, in a paper read before the Society of Naval Architects and Marine Engineers in November, 1918, states that from certain data obtained by him in England, the results given in the following table, with quasi arc flux covered electrodes, are as follows:

Metal Electrode Arc Welding (Quasi Arc)

Plate thickness, inches	Power used per foot run, amps. at 100 V.	K. W. H. at 3 cents	Electrode per foot run in cents	Labor at 65 cents per hr.	Time per foot of weld	Speed in ft. per hr.	Total cost per ft. of weld in cents
1/8	55	.54c.	7.	2.165c.	2 m.	30	9.7
1/4	100	1.35c.	12.9	2.954c.	2 m. 45 s.	22	12.2
3/8	100	4.8c.	19.2	8.66c.	8 m.	7.5	32.66
1/2	120	7.2c.	25.5	13.00c.	12 m.	5	45.7

In this same paper, Mr. Cox reports figures prepared by the Electric Welding Committee of the Emergency Fleet Corporation.

The Possible Cost of a Fillet Weld on a 1/2-inch Plate, Using a Motor Generator Set and Bare Electrodes

Average speed of welding on continuous straightaway work 5 feet per hour
 Amount of metal deposited per running ft. 6 pounds
 Current 150 amperes at 20 volts and 3 kilowatts.
 Motor generator eff. 50 percent—

6 K. W. ÷ 5, equals..... 1.2 K.W.H. per 1 ft. run

1.2 K. W. H. @ 3c per K. W. H. equals 3.6 cents per foot
 Cost of electrode 10 cents per pound,
 and allowing for waste ends, etc., equals 7.2 cents per foot
 Labor at 65c. per hour, equals..... 13.00 per foot

23.8 per foot

The most complete cost data for electric arc welding was compiled at the Fore River Plant of the Bethlehem Shipbuilding Corporation at Quincy, Mass., under the supervision of Mr. W. S. Wakeman, general manager. Tables 1 to 10 give the cost on various items for both riveting and welding and Table 11 shows the summary of these various jobs. On Fig. 83, the percentage of saving is shown by a curve, and direct comparison is made between the use of welding and that of riveting.

Tables 12 to 24 inclusive (to be published in the next issue) show in tabulated form the time required to weld seams and holes. Great care was taken in making up these various tables and the results were checked from work.

Both the General Electric Company and the Lincoln Electric Company welding machines were used and in all cases, welding was made with bare electrodes.

Protective Coverings for Shipbuilding Purposes: Paints

By Horace Holden Thayer*

Continuation of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

WE have dealt with the principal paints whose services in the marine field require the particular consideration of factors which are of little or no importance on land; and as we are not concerned with the uses of paints in general, the pertinency of the above explanatory note will be particularly apparent in this article.

Some proprietary paints are very good for the services for which they are proposed, but others are poor, and the temptation to adulterate paints in order to meet price competition is hard to resist. The formulæ here given will serve as a guide to good practice.

EXTERIOR PAINTS, GENERAL

The standard paint for a vessel's topsides and other exterior work when white or gray is a white lead and linseed oil paint, which can be tinted as required. A trace of ultramarine added to the paint brings out a clear white color, and the addition of carbon black will produce any desired shade of gray. Considerable amounts of white zinc can be used in place of the white lead with good results. At least two coats should be applied over a priming coat, and three coats should be used on woodwork.

Specifications for this paint adopted in 1917 by the United States Shipping Board Emergency Fleet Corporation are as follows:

Zinc oxide—not less than 25 percent nor more than 50 percent. The remainder may be either basic sulphate white lead or basic carbonate white lead, or a combination of the two.

If desired, there may be substituted for a part of the lead pigments either magnesium silicate, silica, barium sulphate, or calcium carbonate, or a mixture of these pigments, in amounts not aggregating more than 15 percent of the total pigment. In any event the pigment portion of the paint shall contain not less than 15 percent of total lead and zinc pigment.

The vehicle shall consist of pure linseed oil, liquid drier and volatile thinner, which may be either turpentine or mineral spirits, or a mixture of these, no rosin shall be present. The total volatile thinner, including that contained in the liquid drier, shall not exceed 10 percent of the total vehicle.

The paint shall contain not less than 64 percent by weight of pigment and weigh not less than 15¼ pounds per gallon. The paint must be satisfactory in every respect including body and freedom from objectionable settling or caking in can. The paint must have satisfactory working qualities, hiding power, drying, color, gloss and durability.

The United States Navy formula No. 6 "outside white," which weighs about 17 pounds 4 ounces per gallon, is along somewhat similar lines, but is called for only as a final coat. Other coats are their "inside white" formula No. 27 which will be referred to later. Formula No. 6 is as follows:

	1 Gallon
White lead, in oil	5 pounds
Zinc oxide, in oil	9 pounds
Raw linseed oil	3 pints
Mineral spirits	3 gills
Drier	2 gills
Ultramarine blue	1/12 ounce

Specifications for white paint for exterior use adopted in

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

1918 by the War Service Committee of the Paint Industry are:

Pigment	62 percent
Liquid	38 percent
The pigment portion shall consist of—	
White lead (basic carbonate, basic sulphate, or a mixture thereof)	45 percent
Zinc oxide	35 percent
Aluminum silicate, magnesium silicate, or a mixture thereof	20 percent
The liquid portion shall consist of—	
Raw linseed oil	75 percent
Varnish	10 percent
Drier	5 percent
Turpentine	5 percent
Volatile mineral spirits	5 percent

A trace of ultramarine blue may be added to make a clear white, which is the color desired.

Special requirement: The paint shall weigh not less than 15¼ pounds per gallon.

Where the topsides are black the pigment is carbon black and the United States Navy formula No. 13 for this paint is:

	1 Gallon
Lampblack, in oil	3 pounds 12 ounces
Raw linseed oil	3 pints 1 gill
Mineral spirits	3 gills
Drier	3½ gills

This paint weighs about 8 pounds per gallon.

The topsides and other exterior surfaces of a large number of steel and wood vessels have been coated with black paints which conform to the following specifications, which appear to allow an undesirable amount of pigment adulterant and of thinner and drier. The writer has no data as to how these paints stand up as compared with the United States Navy paint:

Pigment	15 percent
Liquid	85 percent
The pigment portion shall consist of:	
Carbon black	50 percent
Shale black, aluminum silicate, magnesium silicate or mixture thereof	50 percent
The liquid portion shall consist of:	
Pure linseed oil	40 percent
Pure China wood oil	10 percent
The balance shall be combined drier and thinner.	
The thinner shall be turpentine or volatile mineral spirits or mixture thereof.	

The paint shall weigh not less than 8 pounds per gallon and shall dry within 18 hours after application to a full oil gloss. The carbon black used in the manufacture of this paint must be a good quality, free of grit, shall not contain more than 1 percent of ash and shall be the perfectly calcined product from gas.

All percentages are to be figured by weight.

For spar or spruce color paint, which is used considerably about a vessel, an extensively used formula is about as follows:

	1 Gallon
White lead in oil	14.0 pounds
Yellow ochre in oil	1.4 pounds
Venetian red in oil	.9 ounce
Raw linseed oil	3.0 pints
Mineral spirits	3.6 gills
Drier	1.5 gills

This agrees closely with the United States Navy formula No. 7 for spar color paint, which has a specified weight of 18 pounds 11 ounces per gallon.

Steel decks are preferably protected with two coats of red lead priming paint. Any other paint that may be required is preferably of an abrasive resisting nature such as the boottopping paint referred to in the September issue of this magazine.

INTERIOR PAINTS, GENERAL

When selecting paints for the holds and tween decks of steel ships care should be taken not to have paints that will make the spaces too dark or that will be too light to wear well. Black paints are not desirable for this reason. Gray paints are good for the underside of decks but are not usually desirable elsewhere in cargo spaces. Apart from this feature any good priming paint makes a good hold paint, and in fact some oxide of iron paints that are not desirable as priming paints make very good hold paints for second and third coats. Some proprietary hold paints are the anti-corrosive bottom compositions under another name, and they also give good service as second and third coats on interior steelwork. There are some proprietary paints to which other paints will not adhere but which have excellent anti-corrosive and wear resistant properties; and these also find a good field in holds and similar spaces.

As previously stated, the interior surfaces of wood hulls should not be painted with an oil paint, because the paint plugs up the pores of the wood, and will bring about dry rot, if the wood has not been thoroughly seasoned.

The best pigments for interior paint for accommodations are white lead and white zinc and the best vehicle is linseed oil. The following schedule typifies high grade merchant ship practice for first class accommodations and similar spaces:

- 1 coat of shellac
- 1 thin coat of white priming paint with a vehicle about 40 percent linseed oil and 60 percent turpentine
- 1 white coat of shellac
- 2 coats of linseed oil paint with pigment 60 percent white lead and 40 percent zinc oxide
- 1 coat straight zinc oxide and linseed oil paint
- 1 coat of enamel

For corresponding spaces on government vessels where white the Navy Department requires

- 1 priming coat
- 2 coats of inside white, formula 27
- 1 coat of flat white, formula 29
- 1 coat of white enamel, formula 30

The formulæ for the white paints are as follows:

Quantities Required for 1 Gallon			
	Inside White	Flat White	White Enamel
White lead, in oil...	7 pounds		
Zinc oxide, in oil...	7 pounds (American)	15 pounds 4 ounces	4 pounds (French)
Raw linseed oil	7½ gills		
Mineral spirits	8 1/6 gills	3 pints	
Drier	1½ gills	¾ gill	
Ultramarine blue, in oil	1/12 ounce	2/25 ounce	1/25 ounce
Damar varnish		½ gill	7 pints
Weight per gallon	18 pounds	17 pounds 8 ounces	11 1/16 lbs.

Specifications for flat white and white enamel adopted in 1918 by the War Service Committee of the Paint Industry are:

FLAT WHITE

Pigment	70 percent
Liquid	30 percent

The pigment portion shall consist of—

Lithopone (containing not less than 26 percent zinc sulphide)	80 percent
Zinc oxide	10 percent
White crystalline pigments	10 percent

The liquid portion shall consist of—

Treated oils and volatiles, or varnishes which produce a satisfactory washable flat finish.

The liquid portion shall contain—

Non-volatiles (not less than)	20 percent
Volatiles (not more than)	80 percent

The volatiles shall be turpentine, or volatile mineral spirits or a mixture thereof. Of the total volatiles not more than 2½ percent may be water.

Special requirements: The physical characteristics particularly required are fineness, flowing and flattening. The paint shall weigh not less than 14½ pounds per gallon.

WHITE ENAMEL

The pigment shall consist wholly of—

Pure French process zinc oxide.

The liquid shall consist of—

High-grade varnish resins or treated oils, with such volatiles as are necessary.

It shall not contain more than 1 percent of moisture in any form.

Special requirements: This enamel shall be clear white and dry with a high lustre, to a tough elastic film, within 12 hours. When brushed onto a panel of clean bright tin and allowed to dry for 48 hours, it shall withstand bending over a rod ⅛ inch in diameter without showing cracking or flaking at the point of bending.

Interior paints are the ones in which there is the greatest cutting of values in order to cut prices. Lithopone is used in cheap paints in place of white lead or white zinc and, where the color will allow, domestic oxides and other earth pigments are used. The linseed oil is reduced by extending it with other liquids, some of which are claimed to make the colors more permanent, and the paint, less affected by moisture.

Some proprietary so-called white leads are over 25 percent barium sulphate, which is nothing but a cheap adulterant. Barium sulphate, silica, asbestos or other cheap white mineral adulterants are usually not objectionable up to about 15 percent of the total pigment, as allowed in the United States Shipping Board outside white paint, provided their presence is understood. The chief objection to their use is that they are not opaque when mixed in an oil vehicle, and they reduce the hiding power of the paint.

There are on the market a number of special paints and systems of painting for interiors and a few of them have given very good results in marine service as well as on land. Their merits cannot very well be gone into here, but when anything of the kind is offered the proposers should be asked to show the results of actual service.

PAINTS FOR SPECIAL SERVICES

Cork Paint.—For cork painting the coat next to the priming paint has to be a thick coat of a nature to which the cork will adhere well. Subsequent coats are preferably the same as on adjacent surfaces. The Navy Formula No. 51 for the coat directly under the cork is

	1 Gallon
Whiting	7 pounds 5½ ounces
Interior varnish	5 pints 1 gill
Raw linseed oil	1 gill
Drier	1 gill
Weight per gallon	12 pounds 5 ounces

The grains of cork should pass through a No. 8 sieve but be large enough to be held on a No. 12 sieve.

Paint Under Doublings.—This paint is also of a special nature with good body and waterproofing qualities, and there are proprietary paints on the market for this service.

Seam Cement.—Some of these proprietary compositions offered for both steel and wood ships are of the nature of paints and are preferable to ordinary paints for filling in calking seams, cracks and abrasions on wood ships.

Stack Paint.—Paint for stacks and other particularly hot surfaces is preferably of a special nature and usually contains litharge. Proprietary paints for this service are on

the market, and the Navy Department has the following formulæ for spar color and light gray stack paints, Nos. 8 and 10 respectively:

No. 8		1 Gallon
Silica, dry	2 pounds	
White lead, in oil	6 pounds	
White lead, dry	6 pounds	
Yellow ochre, in oil	1 pound	4 ounces
Litharge	1 pound	4 ounces
Boiled oil	10 gills	
Mineral spirits	8 gills	
Venetian red, dry	1 ounce	
Weight per gallon	20 pounds	10 ounces

No. 10		1 Gallon
White lead, dry	4 pounds	13 ounces
Zinc oxide, dry	1 pound	14 ounces
Lampblack, dry	1½ ounces	
Litharge	5¾ ounces	
Kerosene	2 quarts	
Drier	2½ gills	
Damar varnish	1 quart	
Weight per gallon	13 pounds	

Waterproofing Canvas.—Special compounds of proved merit should be used for this service.

Canvas Preservative.—The Navy Department has a preservative compound for white canvas and a preservative light gray canvas paint of the following formulæ, No. 20 and No. 21 respectively:

	1 Gallon	
	No. 20	No. 21
Paraffine, crude (melting point 103-105 deg.)	1 pound 12 ounces	1 pound 12 ounces
Paraffine oil (specific gravity, 865)	4 gills	4 gills
Mineral spirits	10 gills	10 gills
Kerosene	10 gills	10 gills
Zinc oxide, dry	7 ounces	7 ounces
Lampblack	7/10 ounce	7/10 ounce
Weight per gallon	7 pounds 14 ounces	8 pounds 3 ounces

Machinery.—Paint for main engines and auxiliaries, ice machines and other inside machinery is preferably a varnish vehicle paint.

Inside of Water Tanks.—Many special compounds are available for this purpose. One of these, of the nature of a thin bodied varnish, has shown up well in combination with Portland cement. Another, which is a rubber composition applied hot, has given good results. Bituminous compositions are good for this service. The Navy Department requirements for the washing out of fresh water tanks which have been coated with bituminous solution and enamel have been stated in the June, 1923, issue of this magazine.

Inside of Boilers.—Coatings for the water and steam surfaces of firetube boilers are on the market in considerable numbers but their merits should be carefully investigated. Some of them are used and recommended by the engine room personnel after satisfactory trial. One chief engineer will swear by a cement wash made up of Portland cement and fresh water only. Another will not tolerate cement in his boilers and considers a coating of metallic zinc powder mixed up in clean fresh water to be the only thing. Another has obtained such good results with white zinc mixed up in kerosene oil that he will not use anything else. Another uses a mixture of cement and lime, half and half, in hot water, about the consistency of white wash, with a handful of tallow to the bucketful to keep them in suspension.

VARNISH

A good specification for spar varnish, the principal varnish required on shipboard, was given in the first section of this article appearing in the July issue. There are, however, a number of good proprietary varnishes on the market of which Valspar is generally conceded to be the best. Lists of approved spar varnishes will often include the following:

Valspar	Valentine & Company
Wood oil coating No. 1	Glidden Varnish Company
Aero Rex spar	Sherwin-Williams Company
Spar varnish	Colonial Works
Spar varnish	Howe Varnish Company

Damar varnish is used in paints for inside work and the Navy Department specifications for this varnish embody the following requirements:

COMPOSITION

The varnish shall consist exclusively of a solution of pure damar resin in petroleum spirits (turpentine substitute), and be absolutely free from all foreign matter. It shall contain not less than 55 percent nor more than 60 percent by volume of petroleum spirits.

PHYSICAL CHARACTERISTICS

The varnish when poured on a dry glass plate held in a position inclined 30 degrees to the vertical shall set to touch in not more than 30 minutes. It shall not flash below 105 degrees F., when tested in an open tester by Tagliabue's method.

COMPARISON WITH STANDARD SAMPLES

The varnish shall be equal to the standard sample on hand at the various navy yards, in body, clearness, lightness of and freedom from color; and when mixed with French white zinc: in flowing qualities, covering properties, gloss, finish, and durability.

Mixing varnish called for by the Navy Department in its formulæ for boottopping paints has the following specification requirements:

QUALITY

Mixing varnish shall be made of high-grade material, of good manufacture, and free from any ingredients which may affect its suitability as a mixing varnish for boottopping paint.

PHYSICAL PROPERTIES

The varnish shall be clear and free from sediment or suspended matter. When flowed on glass plate placed at 30 degrees to the vertical the material shall not come off when touched lightly with the finger after two hours, and shall dry elastic in from 12 to 16 hours at a temperature between 60 degrees and 80 degrees F. The varnish shall mix readily with the pigment and remain in solution when mixed. When tested in an open tester by the method known commercially as "Tagliabue's method" it shall not flash below 100 degrees F. When mixed and ground as per the following formula—for one gallon—

Mixing varnish	2 pints
Drier	2 pints
Petroleum spirits	2¾ pints
Lampblack, in oil	31½ ounces
White zinc, American, dry	30 ounces

the boottopping paint shall in service retain its color and body and shall not flake or peel off due to the alternate action of the water and air. When applied to the steel plating the boottopping paint shall dry sufficiently within 4 hours to permit of the application of a second coat.

GENERAL COMPOSITION

The base of the mixing varnish shall be either china wood oil or linseed oil, or both, and varnish resins or such other ingredients as may be deemed essential by the manufacturer to produce a mixing varnish complying with the requirements of paragraph 3 (just above.)

ACCEPTABLE BRANDS OF MIXING VARNISH

Bids for mixing varnish will be considered from only those manufacturers whose mixing varnish has been found, after service tests, to be satisfactory for the purpose, and the department reserves the right to reject any bids based on varnishes which are unknown or have not been subjected to the required service tests.

Varnish for inside bright finish work goes by the name of interior varnish, and Navy Department requirements for it are a good guide for the selection of varnishes that may be expected to give good results. They are as follows:

MATERIALS

The manufacturer is given wide latitude in the selection of raw materials and processes of manufacture, so that he may produce a varnish of the highest quality.

GENERAL REQUIREMENTS

(a) The varnish shall be suitable for general interior use, including both rubbed and unrubbed finish, exclusive of floors. It must be capable of easy application with a brush in the ordinary manner, according to the rules of good standard practice, must flow out to a good level coat, free from runs, sags, pits, or other defects, and dry with reasonable promptness to a hard, somewhat elastic glossy coating which can be rubbed in 48 hours or less.

(b) The varnish shall be clear and transparent and not darker in color than a solution of 3 grams of potassium dichromate in 100 cubic centimeters of pure sulphuric acid, specific gravity 1.84.

(c) It shall have a flash point (closed-cup) of not below 32.2 degrees C. (90 degrees F.) and shall contain, by weight, not less than 45 percent of non-volatile matter.

(d) The varnish shall set to touch in not more than 4 hours, dry hard in not more than 24 hours, and dry to rub in not more than 48 hours, under standard conditions of temperature and humidity.

(e) The film on metal shall stand rapid bending over a rod 3 millimeters ($\frac{1}{8}$ inch) in diameter.

(f) The varnish shall have good brushing, flowing, covering, leveling, and rubbing properties, and shall show no impairment of lustre or other defect when used where natural or illuminating gases are burned or when subjected to air currents during the process of drying or application.

(g) The dried film shall stand application of cold water for not less than 18 hours without whitening or showing other visible defects.

TESTS

(a) Deliveries will, in general, be sampled and tested by the following methods, but the Department reserves the right to use any additional available information to ascertain whether the material meets the specifications.

(b) It is mutually agreed by buyer and seller that a single package, out of each lot of not more than 100 packages, be taken as representative of the whole. Whenever possible, an original unopened container shall be sent to the laboratory, and when for any reason this is not done the inspector shall thoroughly mix the contents of the container sampled, transfer not less than 1 quart to a clean dry glass bottle or tin can which must be nearly filled with the sample, securely stoppered with a new clean cork or well-fitting cover or cap, sealed, and distinctly labeled by the inspector.

(c) The inspector should take a duplicate from the container sampled, to be held for check in case of dispute, and, when requested, should take a sample for the seller.

(d) The tin panels used in the following tests shall be cut from bright tin plate weighing not more than 25 grams nor less than 19 grams per square decimeter (0.51 to 0.39 pound per square foot). (Bright tin plate, 0.0109375 inch, should weigh about 0.44 pound per square foot. It is important that the tin plate used shall be within the limits set.)

(1) *Appearance*.—Pour some of the thoroughly mixed sample into a clear glass bottle or test tube and examine by transmitted light. The varnish must be clear and transparent.

(2) *Color*.—Prepare a standard color solution by dissolving 3 grams of pure powdered potassium dichromate in 100 cubic centimeters of pure concentrated sulphuric acid of specific gravity 1.84. Gentle heat may be used, if necessary, to perfect the solution of the dichromate. The standard color solution and a sample of the varnish to be tested shall be placed in clear, thin-walled glass tubes of the same diameter. The color comparison shall be made by placing the tubes close together and looking through them by transmitted light. The tubes used for this test should be 1.5 to 2.0 centimeters ($\frac{5}{8}$ to $\frac{13}{16}$ inch) in diameter and shall be filled to a depth of at least 2.5 centimeters (1 inch). (Since the potassium dichromate-sulphuric acid must be freshly made for this color comparison, it is frequently more convenient to compare samples with a permanently sealed tube of varnish which has previously been found to be slightly lighter in color than the standard solution of 3 grams dichromate in sulphuric acid. When samples are found to be darker than this standard tube of varnish, the dichromate standard should be made up for final decision.)

(3) *Flash Point*.—Determine with either the "Tag" or Elliott closed-cup tester. The former is preferred.

(4) *Nonvolatile matter*.—Place a portion of the sample in a stoppered bottle or weighing pipette. Weigh container and sample. Transfer about 1.5 grams of the sample to a weighted flat-bottomed metal dish about 8 centimeters (3.1496 inches) diameter (a friction-top can plug). Weigh container again and by difference calculate the exact weight of the portion of sample transferred to the weighed dish. Heat dish and contents in an oven maintained at 105 degrees to 110 degrees C. (221 to 230 degrees F.) for three hours. Cool and weigh. From the weight of the residue left in the dish and weight of the sample taken, calculate the percentage of nonvolatile residue.

(5) *Drying time*.—Pour the varnish on a clean glass or bright tin plate not less than 15 centimeters (6 inches) long and 10 centimeters (4 inches) wide. Place the plate in a nearly vertical position in a well-ventilated room, but not in the direct rays of the sun. The temperature of the room should be from 21 to 32 degrees C. (70 to 90 degrees F.). In cases of rejections on drying time, standard conditions of temperature and humidity shall be 70 degrees and 65 percent, respectively. The setting and drying time specified shall be obtainable under these conditions. The film is tested at points not less than 2.5 centimeters (1 inch) from the edges of the film by touching lightly with the finger. The varnish is considered to have set to touch when gentle pressure of the finger shows a tacky condition, but none of the varnish adheres to the finger. The varnish is considered to have dried hard when the pressure that can be exerted between the thumb and finger does not move the film or leave a mark which remains noticeable after the spot is lightly polished. If rapid light rubbing breaks the surface, the sample is considered not to have satisfactorily dried hard. In case the test shows time of setting to touch or drying hard more than 4 and 24 hours, respectively, two additional tests shall be run on different days, and if the varnish does not meet the above drying and hardening requirements on both of these additional tests, it shall be considered unsatisfactory.

(6) *Toughness*.—Thoroughly clean, with benzol, a sheet of bright tin 7.5 by 13 centimeters (about 3 by 5 inches). Flow the varnish on one side of the tin plate and set in a vertical position in a well-ventilated room, not in the direct rays of the sun, at a temperature not below 21 degrees C. (70 degrees F.).

After the varnish on the tin plate has dried for 48 hours bring to a temperature between 21 and 24 degrees C. (70 to 75 degrees F.), and with the varnish film on the outside bend rapidly over a rod 3 millimeters ($\frac{1}{8}$ inch) in diameter. The film must show no evidence of cracking or flaking.

(7) *Water resistance*.—Prepare a panel as in (6) and let it dry in a well-ventilated room for 48 hours. Place the panel in a beaker containing about 2.5 inches of distilled water at room temperature (immersing the end of the panel which was uppermost during the drying period) and leave in water for 18 hours. The varnish shall show no whitening and no more than a very slight dulling when observed after removing the panel from the water and drying for 2 hours.

(8) *Flowing and rubbing properties*.—Thoroughly clean, with benzol, a glass plate about 15 by 20 centimeters (6 by 8 inches). Flow the varnish so as to entirely cover one side of the panel and stand in a nearly vertical position with the long edge horizontal for 8 minutes. Then draw lightly a 25 millimeters (1 inch) section of a hard-rubber comb (having 8 to 10 teeth to the centimeter) horizontally across the varnish surface, first 2 centimeters (0.7874 inch) from the bottom and then 2 centimeters (0.7874 inch) from the top of the plate. Let panel stand in the same position for 20 minutes longer, then lay flat. An exaggerated condition of a dusty room shall be created by rubbing some cotton batting between the hands immediately over the panel. Let panel dry for a total of 48 hours in a well-ventilated room. If the comb marks show at this time, the varnish shall be rejected. If no comb marks show, the surface shall then be rubbed with pumice flour, water, and a felt pad with long, even, firm strokes back and forth in one or another direction, but not in circles, until every portion of the panel has been rubbed. Most of the pumice will then be removed from the pad and panel, and the varnish film given a "water rub" with the pad.

A satisfactory rubbing varnish in the above test will yield a smooth, dull film even at those places where the dust particles have been encrusted in the film, and shall show no spots where the pumice has been ground into and become attached to the film, nor show any other evidence of gumming. No sweating shall occur anywhere on the film in 18 hours after rubbing.

(9) *Gas test—Apparatus*.—The necessary apparatus consists of a glass bell jar approximately 20 centimeters (8 inches) in diameter and 30 centimeters (12 inches) in height, inside dimensions, having a ground-glass rim; a ground-glass base plate of suitable size; a small kerosene glowlamp without chimney or a small alcohol lamp filled with kerosene, using a round wick not over 6 millimeters ($\frac{1}{4}$ inch) in diameter and adjusted to give a flame 2 centimeters ($\frac{4}{5}$ inch) in height. A wire or a light wooden frame is fitted inside the jar and provided with a support for holding a disk of tin plate 15 centimeters (6 inches) in diameter in a horizontal position 5 centimeters (2 inches) above the wick of the lamp. The frame must also be provided with several other supports above this disk for holding in a horizontal position the various varnished panels under test. The test panels consist of semicircular pieces of bright tin plate approximately 15 centimeters (6 inches) in diameter.

The form and arrangement of the above apparatus is designed to provide an even distribution of the products of combustion over the test panels.

Method.—First determine the normal time required for the varnish under examination to set to touch at room temperature. Divide this time by 5 to arrive at the different drying periods at which the varnish is to be tested in the gas tester. Thus, if a varnish sets to touch in 5 hours, samples should be tested for resistance to gas at drying periods of 1, 2, 3, and 4 hours; it is needless to use the fifth or 5-hour period for the above varnish, as a varnish which has set to touch is practically immune to injury from gas fumes. Similarly a varnish which sets to touch in 1 hour should be tested for resistance to gas at drying periods of 12, 24, 36, and 48 minutes.

Example.—A varnish which sets to touch in 5 hours is tested as follows:

First, clean two of the semicircular, bright, tin-plate panels carefully with benzol. Flow the varnish on one-half of panel No. 1 at say, 10 A. M., and allow to drain in a nearly vertical position at room temperature. At 11 A. M. flow the varnish on the other half of panel No. 1; allow to drain as before. At 12 M. varnish one-half of panel No. 2 and at 1 P. M. varnish the other half as above. At 2 P. M. place the two panels close together in a horizontal position on the upper supports of the frame. Light the lamp and set it under the circular tin. Place the bell jar in position,

centering it as nearly as possible, properly seated on the ground-glass plate. If the chamber is tight and lamp properly adjusted, the flame will be extinguished in about 4 minutes. After the panels have been in the chamber for half an hour, remove the bell jar and examine the varnished panels for gas effects.

The varnish on all four sections should remain bright and clear without trace of pitting, "crow's footing," frosting, or other defects.

PACKING AND MARKING

(a) Varnish shall be delivered in 5-gallon or 1-gallon tin cans, as specified, packed 10 gallons per case.

(b) Five-gallon cans and cases for same shall be made in accordance with the latest issue of Navy Department Specifications for Five-Gallon Tin Cans and Shipping Cases.

(c) One-gallon cans and cases for same shall be made in accordance with the latest issue of Navy Department Specifications for One-Gallon Tin Cans and Shipping Cases.

(d) Each can shall be labeled with the name of the material, the quantity, and the name of the manufacturer.

(e) Cases shall be marked with the name of the material, the name of the contractor, and the contract or order number under which delivery is made.

(To be continued)

Insurance Cases Adjusted in Court Attract Attention

Unusual Circumstances Involved in Establishing Loss Claims

—London Underwriters Hard Hit—Lake Grain Situation

By "Bordereaux"

THE value of the *Proteus*, which was wrecked by collision with the *Cushing* on August 19, 1918, has been increased by \$500,000 and is now fixed at \$1,225,000 by authority of the United States Circuit Court of Appeals, Second Circuit, thus modifying the decree of the lower tribunal. The Southern Pacific owned the *Proteus*, and the Standard Oil the *Cushing* the former was a total loss, and the underwriters have paid on account of both hull and cargo. The cargo owners were represented in the appeal by Bigham, Englar and Jones. The action was of interest to them because additional recovery from the carrier is made possible by the increase in value.

The *Proteus* was insured under full form for \$600,000, half being placed in this market and half abroad. She was also insured 15 percent on disbursements, largely here.

London Underwriters Hit

LONDON underwriters will have a big loss to face in the case of the steamer *Ferrara*, practically destroyed by fire near Sabang. So far as can be gathered, a shipment of opium from Persian Gulf to Macao, insured on a value of about £200,000, has been destroyed. Practically the whole loss will fall on the London market. Another cause for anxiety was the stranding of the steamer *Magicstar*, one of the fleet owned by the Union Cold Storage Company, which ran ashore in the Yang-tze-kiang, after leaving Hankow, with nearly 4,000 tons of eggs in refrigeration. This cargo may be worth over £200,000. Up to 20 guineas was paid against the risk of total loss of the steamer, and 40 guineas against the risk of total loss of the cargo, but the rate dropped to 5 guineas on the hull before she was floated. The steamer was of 5,534 tons, and is insured on a value of £100,000. The owners run the risk of particular average, and also part of the total loss risk. The steamer *Cid*, which ran ashore on the south coast of the Straits of Gibraltar, near Cires Point, when bound from Spain to London, was quoted at 35 guineas against the risk of total loss, but was re-floated after the rate had dropped to 10 guineas. The

steamer was of 1,847 tons, and owned by the Macandrew Line, being insured on a value of £65,000.

Establishing Loss Claims

THE following case, decided in the English courts, in which an American company was involved, has attracted considerable attention in this country:

In the King's Bench Division on July 24, Mr. Justice Rowlatt delivered judgment in the case of Zachariessen v. Importers and Exporters Marine Insurance Company and others.

Plaintiffs insured with defendants a vessel carrying a cargo of coal from Newport News to Gothenburg "against mine risks only as per Norwegian conditions, including missing." The vessel left Newport News on October 1, 1920, and was never again heard of. Plaintiffs claimed for a loss under the policy contending that they could recover, if the ship was "missing" from any cause whatsoever, but defendants argued that they were only liable, if the vessel was missing by reason of damage caused by a mine.

Council for defendants submitted that the words "mines only" were words of definition and exclusion and limited the range of the insurance. The evidence showed that the vessel was already fully insured in Finland against ordinary marine risks, and there would be no need to take out this policy in relation to such ordinary risks. The intention clearly was that this policy should cover only the risk of mines. On the facts it was improbable that the ship was lost by anything but an ordinary peril of the seas. At that time there were several derelicts drifting about the Atlantic and, if this vessel had struck one of them in the dark, she would, with her heavy cargo of coal, almost certainly have sunk at once. To say that the ship was lost owing to striking a mine was mere conjecture, and that was not enough to make the underwriters liable. There must be a legitimate inference from the known facts.

In his judgment Mr. Justice Rowlatt said that the only point for decision was the construction of the words "mines

only, including missing." On the question of burden of proof there was really no difficulty or obscurity in principle. If a ship was no longer to be found afloat she must have sunk, and if it was desired to claim for a loss from some cause other than an ordinary peril of the sea, the claimant must prove a loss by that specific cause. The proof might be given by direct evidence, or it might be given by inferential evidence; and inferential evidence might be very strong. The contention of the plaintiffs was that the underwriters had agreed that, if the ship was missing and nothing further was known, it should be presumed in the plaintiff's favor that the loss was due to a mine. The contention of the defendants was that there must be inferential evidence of a loss by mine before the defendants could be liable. On the whole, he thought that the contention of the plaintiffs was right; the underwriters, in effect, agreed that, if the ship was missing and if nothing else was known, it should be presumed that the loss was attributable to a mine. There must therefore be judgment for the plaintiffs. On the facts, he could not agree with the plaintiffs that there was anything to show that the loss was due to a mine; there was really no evidence from which that could be inferred, and it was a mere guess.

Lake Grain Situation

ONE of the subjects to which New York marine underwriters have given most attention this summer has been that of the lake grain situation. An important special meeting was held in the Board Room of the Board of Underwriters of New York for the purpose of considering the effect upon the American marine market of the recent legislative action of the Canadian Parliament with respect to vessel charterers. Charles R. Page, of the Fireman's Fund, presided; about thirty were present. The outcome of the discussion was to charge Chairman Page with the appointment of a committee of three, who will investigate the whole matter and report back their findings.

Mr. Page's committee selection was as follows: Chairman, Hendon Chubb; Galloway C. Morris, third vice-president of the Insurance Company of North America, and W. J. Roberts, United States manager of the Standard Marine of Liverpool.

The measure passed by the Canadian Parliament on June 30 is entitled "Inland Water Freight Rates Act, 1923." The section that especially interests the underwriters and brokers is No. 7. That section, and the penalty provided for its violation, are as follows:

It shall be unlawful for any person who is a vessel broker or person engaged or acting as agent or otherwise in the chartering of any vessel or in contracting for the hire or letting of cargo space for the carriage of grain from Fort William or Port Arthur to any port or place in Canada or in the United States by lake or river navigation to solicit any risk, or to issue or deliver any receipt or policy of insurance or to collect or receive any premium in whole or in part, or to inspect any risk, or to adjust any loss, upon, for or in connection with any consignment of grain so to be carried.

Anyone who counteracts any provision of Sections 6 or 7 of this act, or who fails or neglects to comply with any of the provisions thereof to which he is subject, shall be guilty of an offence and liable therefor to a penalty not exceeding \$1,000 and not less than \$100, or to imprisonment for a term not exceeding three months, or, if a corporation, shall be liable to a penalty not exceeding \$3,000 and not less than \$500; and any such offence may be prosecuted and the penalty therefor enforced or recovered either upon indictment or upon some reconviction before any police, stipendiary or other magistrate having jurisdiction of two justices of the peace.

This act is intended to regulate shipping rates of grain transported for interprovincial, foreign or export trade; it shall therefore not apply to grain carried locally to be ground or to be consumed in the province in which the shipment originates, but the burden of proof that any shipment of grain is within the exception shall rest upon the carrier.

In view of this drastic movement it appears to be a question as to whether there can be devised some method of concerted action as respects the handling of lake grain insurance,

or else an abandonment of the situation to promiscuous "sharp-shooting" at accounts, with the consequent probability of a general rate war. Those who were party to the old vessel agency combination would, very naturally, like to see something of the sort reinstated; while the outsiders find, in the present mix-up, a fine opportunity to break in and "get theirs." It is suggested that an effective device would be the establishment at Winnipeg of a company that could act as a kind of insurance clearing house through which coverage might be effected for all the assured in one central agency, and thus stabilize rates and conditions. The action of Canada is bound to be felt by American underwriters. If the vessel charterer may no longer pass his charge along to the insurer, it means that insurance rates will now be quoted on a net basis. The question is, what is the net rate to be? Will the net rate, plus the commission, represent much, if any, difference to the underwriter as compared with the 35 percent regularly paid the vessel agents under the old arrangement?

Lake grain is carried in freighters that are the property of the big steel companies. When the movement of ore has largely subsided and grain is demanding shipment, in the fall, it has been customary for the vessel agents to arrange for the chartering of whole fleets from the steel men, which is naturally a much more satisfactory arrangement for the latter than to bother over getting individual grain shipments, here and there, for their idle vessels. The charterers, being in possession of practically all the transportation facilities of the lakes, then dispose of cargo space to shippers, and in lieu of a chartering fee reserve to themselves the placing of the insurance. As has been stated above, they are paid a commission of 35 percent by the underwriters. Out of that commission the charterer pays all handling charges, for loading and unloading, demurrage, etc., etc. The assumption of these charges is a matter of great importance to grain dealers. At Winnipeg, for example, the most active competition exists among dealers, and their quotations not infrequently are so close as to leave a possible profit of scarcely one-eighth of a cent a bushel. What would become of this narrow margin, if an unexpected demurrage charge had to be met? It would certainly mean a loss at Montreal. Thus we find the Canadian dealer already groaning under the new law, and in a frame of mind to welcome some sort of a return to old conditions.

Prove Insurable Interest

JUSTICE FORD, of the Supreme Court of New York County, in a recent decision emphasized the essential importance of establishing insurable interest in merchandise covered under a marine insurance policy, if a plaintiff hopes for recovery.

Action had been brought by Anthony A. Lutfy against the Bankers' and Shippers' on a policy issued to W. Reed Williams, and/or as agent, which the plaintiff contended had been assigned to him together with all claims under it. He then declared that a loss from theft and pilferage had occurred while the cargo was on board the steamer *Charlton Hall* en route from New York to Santiago. Counsel for the insurance company raised the contention that there no longer existed the old legal distinction between the requirements of insurable interest in marine policies and fire policies, and that, in order to recover, a person suing on a policy of marine insurance must allege an insurable interest and establish facts showing such an interest at the time of the loss.

A request was made for such a ruling, the argument being that otherwise marine insurance policies would be subject to condemnation by the statute of the State of New York avoiding wagers and gambling contracts of every sort. Decision was reserved by the court at the time, but Justice Ford has now handed it down, sustaining the contentions of the attorney for the Bankers' and Shippers'.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Barrels of Oil per Knot

Q. (1,214).—What is the average consumption in barrels of oil per nautical mile?

A. (1,214).—It is impossible to answer this question as worded as the power and speed of the vessel enter into the problem.

Assuming the indicated horsepower as 2,200, speed of vessel 12 knots and pounds of fuel oil per indicated horsepower as 1.4, then the fuel consumption per knot would be

$$\frac{2,200 \times 1.4}{12 \times 316} = 0.812 \text{ of a barrel.}$$

Average Miles per Barrel of Oil

Q. (1,215).—What are the average miles per barrel of oil?

A. (1,215).—Making the same assumptions as in Q. (1,214) the nautical miles per barrel would be

$$\frac{316 \times 12}{2,200 \times 1.4} = 1.23$$

Formula for Block Coefficient

Q. (1,217).—Is there any method of obtaining the displacement and block coefficient of a steamer when no drawings of the hull are available?—C. R. K.

A. (1,217).—The one can not be determined without the other unless drawings are available. Should the displacement be known the block coefficient may be figured, or vice versa, from the formula

$$\text{Block coefficient} = \frac{\text{Displacement} \times 35}{\text{Length} \times \text{Beam} \times \text{Draft}}$$

where length is at waterline and beam is the greatest immersed breadth.

Rate of Depreciation of Steel Ships

Q. (1,219).—I am particularly interested, at present, in obtaining data on the actual rate of deterioration in steel vessels (or other steel structures in which the conditions would be similar) or on what might be termed the "progressive depreciation," i. e., assuming that the percentage, whatever it might be, would not be uniform, but would increase on a sliding scale with the age of the vessel, what should this scale be?

A. (1,219).—As you suggest, the depreciation in ships probably does not progress at a constant rate. However, there are so many contributing causes that it is difficult to establish from actual practice any law that may be considered to apply with even a fair degree of accuracy.

Probably one of the principal causes of depreciation in the value of ships has nothing to do with the deterioration in the material of the hull or with the wear and tear on the machinery. It is the impossibility of keeping ships or their

equipment, when they once enter service, strictly up to the latest requirements of that service. For instance, it has been stated that ten years is about the useful life of certain types of cargo carriers on the Great Lakes due to the constant progress made in loading and handling appliances and in the size and speed of the vessels used in this service. Of course, these vessels are not worn out at the end of so short a period but they are obsolescent, if not actually obsolete, at the end of this period. In a similar manner, high class Atlantic passenger vessels are continually being transferred from this to other services less exacting as new devices contributing to luxury, comfort, safety or economy are from time to time introduced rendering vessels not so equipped obsolete by that much.

If the question of obsolescence be ignored, we are not much better off unless it is possible to examine in detail carefully kept cost sheets for a large number of vessels over a long period of years. The repairs made and paid for from time to time are often contingent upon the conditions of the service or business or upon the urgency of the repairs themselves. It results that a vast amount of research is necessary in order to discover any general trend. The following figures for two large sea-going tugs will serve to illustrate this point. These figures cover costs under the head of wear and maintenance for hull only.

Years elapsed since entry upon service	Cost—Wear and Maintenance	
	Tug No. 1	Tug No. 2
1	\$514	\$947
2	1,673	578
3	7,448	2,869
4	3,433	3,367
5	3,133	5,018
6	9,421	7,924
7	106	13
8	789	9,205
9	13,664	8,077
10	7,684	8,520
11	489	3,847
Total for 11 years.....	\$48,354	\$50,365

Approximately the same amount was spent on each of the two vessels. In each case the amount expended during the last five years was greater than that expended during the first five years. If, however, these costs be plotted upon a time base, they do not indicate with any certainty a law governing expenditures for a given time in service.

The following figures taken from a paper by John Hick read in 1907 before the North East Coast Institute of Engineers and Shipbuilders are of interest:

- Of 28 steel boilers removed from ships—
- 6 had been in service 8 to 12 years and were removed because of overheating.
- 3 had been in service 8 to 14 years and were removed because of corrosion.
- 4 had been in service 13 years and were removed because of corrosion of combustion back or uptakes.
- 2 had been in service 23 years and were removed because of front tube plate corrosion.
- 2 had been in service 7 years and were removed because of chamber stays corrosion.
- 6 had been in service 16 to 20 years and were removed because of wastage of boiler shell.
- 5 had been in service 25 years and were removed to fit new boilers.

In the same paper three instances of deck plating removal after 13 years' service due to corrosion are given.

It is understood that the regular British practice is to set aside annually for depreciation at the rate of 5 percent of a vessel's first cost. Thus funds become available for replacement after about 20 years of service.

LETTER TO THE EDITOR

The Diesel and the Future

TO THE EDITOR:

Professor Chapman has shown some very interesting figures in the pages of this magazine, particularly in connection with the operating costs of Diesel vessels. These figures are so complete and have been so well worked out that they may safely be taken as a guide for shipowners to follow in considering the question of Diesels versus steam. In general terms, it is brought out that the saving in fuel in the Diesel is practically offset by the capital charges, in the cases of new tonnage.

There are certain factors, however, which should be carefully considered by shipowners in shaping their policies for the future, and I fully believe that the Diesel question should be closely analysed, both as to its present and its future. It is not enough for us to say that from the present viewpoint the decision is a toss-up. We know what it will cost us today to build two similar ships, one steam and one Diesel, and we know that the operating expenses will be about the same, including capital charges. This condition, however, may be altered in a day by the cost of steel, the cost of labor, the price of oil, the world freight market and countless changes in operating conditions. We might favor the steam plant this year and the Diesel next, purely from the standpoint of dollars and cents.

Personally, the writer has unlimited enthusiasm for the Diesel, believes in its theory and merit, and fully expects the Diesel to supplant steam, nor is this any new idea with him. But this enthusiasm has been kept in check because the balance sheet does not as yet entirely prove that the Diesel is to supplant the steam. Of course, from an engineering viewpoint, the Diesel is almost a thing of beauty. Here is a machine which burns its own fuel and has no losses other than those contained within the engine itself. No transfer of heat from oil to water through boiler steel, no British thermal units going to waste in the stack and atmosphere, no long steam leads from boilers to engines. This Diesel engine per horsepower saves two-thirds of the fuel and with it all is efficient and reliable. These points do not have to be proved to engineers. The only question is, will we be able to take advantage of this saving and run our ships at greater profit than with steam? The answer is somewhat uncertain.

In the first place, however, let us turn back to the advent of steam over sail, when our clippers were running rings around everything on the high seas. We were masters of the whole situation in those days, and the world acknowledged us as such. We had cheap materials, efficient shipbuilders, shrewd shipowners and dauntless seamen. We had the world beaten at one of its oldest games. Even after our competitors copied our designs, we still outsailed them, and they were forced to find some new method or acknowledge defeat.

They found their new method in utilizing steam instead of winds, and when they adopted it, our own people, believing that they were securely seated at the top of the world, looked on with a feeling of indifference. We considered steam—and turned it down with what is now clear evidence of lack of foresight. Our ships disappeared slowly from the sea, from which they have continued to be conspicuous by their absence.

The present day value to us, of this tremendous mistake of the past, should cause us to look into the Diesel question so clearly that we cannot go wrong. Nor is it a question for engineers only, it is the real live issue today which should be right before the board of directors, whose decision should not be based on today but upon the probable events of the next twenty years. Clear vision and clear thinking are required.

Secondly, what information can we gain from developments in Europe? The British, Danes and Norwegians, whose present maritime prestige need not be discussed, are going into Diesels in no half-hearted way. Look over any shipping publication and you find a new motorship proposed, laid down or launched, and even a double acting Burmeister & Wain is being built after successful experiments have proved its worth. Hardened Scotch engineers, masters of the steam job, are looking with favor on the new engine, and who could be more difficult to convince? Motorships have arrived on the other side of the Atlantic for permanent service and the European engineers are pretty clear thinking people. They would not now be building motorships, if they had not looked clearly into the economic possibilities involved, just as they saw what steam would do almost a century ago.

In the third place (and this seems the meat of the whole proposition), what is the future of the oil supply? If the writer recalls correctly, the geologists have set some sort of a definite limit to the oil supply of the world, yet fortunately for us, every now and then some new oil field develops which gives us a little more oil in sight. We will hope that new fields will always be coming through the earth's crust in order that the world may continue to benefit by this wonderful fluid fuel. Still, the oil supply is not nearly so well guaranteed as the coal, but regardless of the limit to the future supply, how are we to account to posterity for the millions of tons which are wasted annually in steam plants of all kinds?

If there were only two hundred oil burner steamers in the world today, and each of these vessels burned seven thousand tons a year, the preventable loss of energy amounts to more than one million tons of fuel oil, for this is approximately what would be saved, if the two hundred ships were Diesel engined. The same cargoes could be carried, the same speed would be maintained, and ten million dollars would be saved on the fuel bill. Furthermore, if every oil burning freighter in the world today were converted to Diesel, and thus materially cut into the demand for oil, the price would go down and a further saving to the shipowner would result. Going further into the conservation of energy involved, it would be a positive national asset, if we could cut down the rate at which we are now burning oil, exhausting nature's bounty just because it happens to flow.

The day may not be far off when certain legislative restriction will be placed on the use of oil; we may also witness the day of our own oil supply running so low that we will have to import for our own uses, at which time we may be forced to choose between coal and Diesels. These and other conjectures ought to have our closest attention, and no decisions made without full possession of all the facts. This problem is none too small for the best minds among our financiers, engineers, geologists and statesmen, and even we lay-people, whose ordinary function is to "carry on," ought to contribute our thoughts and ideas.

In conclusion, and in reiteration, the writer believes that the Diesel is not only holding its own, but will make immense strides in the future. The signs point to an age of oil-engined propulsion, certainly for cargo carriers, probably for passenger vessels. Will we accept our opportunity or refuse it?

New York.

K. H. DONAVIN,

Assistant Manager, Operating Department
International Mercantile Marine Company

PERSONAL MENTION

C. P. KRAMER is acting secretary of the United States Shipping Board.

SIR JOHN BILES, the eminent British naval architect, was a visitor in New York last month.

HARRY ANNING, formerly Portland manager for Sudden and Christenson, has joined the staff of Norton Lilly and Company.

FRED CHASE, for seventeen years with the Admiral Line, has been appointed general agent for Struthers and Barry at Los Angeles, Cal.

THEODORE H. JACOBS is in charge of the Pacific coast passenger office of the United American Lines at 230 California street, San Francisco.

KIRKWOOD H. DONAVIN, formerly assistant to the manager of operations at the International Mercantile Marine Company's Chelsea Piers, New York, has been appointed resident representative at San Francisco of the operation department of the Panama-Pacific Lines. Born in Ohio in 1886, Mr. Donavin was educated for American naval service and graduated from the Naval Academy in Annapolis in 1908. For five years he was on naval duty in Pacific waters and for a year he was stationed in the Far East. He also spent five years in submarine service. In 1920 he was on the staff of Admiral Hilary P. Jones, now commander of the fleet. Upon leaving the

Navy in 1920, Mr. Donavin joined the shore staff of the International Mercantile Marine Company, New York.

CLIFFORD SMITH, formerly secretary of the United States Shipping Board, has become assistant to the managing director of the Board for Brazil.

A. P. ALLEN, formerly sales manager of the Federal Shipbuilding Company, Kearny, N. J., has become associated with Pacific coast lumber interests.

GORDON P. WHITE, one of the directors of the Baltimore Chamber of Commerce, has become a partner in the firm of Adams and Company, steamship agents and brokers of Baltimore.

A. T. B. SHIELS, former American Bureau of Shipping surveyor, has opened an office for general practice as marine surveyor and consulting engineer at 412 Bay Building, 1213 First avenue, Seattle, Wash.

EDWARD P. FARLEY, chairman of the Shipping Board, has been elected president of the Emergency Fleet Corporation. At the same time the scope of the duties of Vice-President Sidney Henry have been broadened to include, in addition to the general supervision of the Department of Sales and Finance, the administrative department, statistical department, the personnel division, the department of investigation and the field forces.

JOHN F. LAMCKE, formerly port engineer for the Shipping Board during the war; assistant superintending engineer for

the Cosmopolitan Steamship Company, Port of New York; superintendent engineer of the Green Star Steamship Company at Baltimore and consulting engineer and marine surveyor at Baltimore, has joined the Maintenance and Repair Department of the United States Shipping Board, 45 Broadway, New York.

CAPTAIN REGINALD ROWEN BELKNAP, U. S. N., commanding officer of the new battleship *Colorado*, commissioned last month at the yards of the New York Shipbuilding Corporation, Camden, N. J., entered the Naval Academy in 1887. He served in the Spanish war, the Philippine insurrection and the Boxer campaign and in 1909 was decorated for service in connection with the Messina earthquake relief. From 1915 to 1917 he was commander of the mine laying and mine sweeping branch of the Atlantic fleet and in May, 1917, he was promoted to the rank of captain. Captain Belknap was awarded the Navy Distinguished Service medal for service in connection with fitting out and afterwards commanding the American mine laying squadron in the northern mine barrage operation in the North Sea. From 1919 to 1920 he was in command of the battleship *Delaware* and more recently was on the staff of the Naval War College.

Captain R. R. Belknap, U. S. N.

LIEUTENANT-COMMANDER F. T. LEIGHTON, U. S. N., has been appointed engineering officer of the battleship *Colorado* and assumed his duties with the commissioning of this new vessel at Camden, N. J., last month. Lieutenant - Commander Leighton was appointed to the Naval Academy at Annapolis from Pennsylvania in 1905. After his graduation from the Naval Academy and subsequent service at sea Lieutenant-Commander Leighton entered the Post-Graduate Engineering School from which he was graduated in 1917. During the World War he served as executive and repair officer of the United States submarine tender *Savannah*; later he was assigned to special duty abroad and was stationed in London.

Lt.-Commander F. T. Leighton, U. S. N.

Biography of Sir William White

Messrs. E. P. Dutton & Company, 681 Fifth Avenue, New York City, will shortly publish an American Edition of the "Life of Sir William White." This biography covers the whole period of naval construction from the beginning of steam propulsion and the building of iron ships to the opening of the *Dreadnought* era and the fitting of the *Mauretania* with turbines. It thus covers the most important period in the development of naval architecture and marine engineering and becomes a valuable work of reference.

The Month's Shipping and Shipbuilding News in Brief

Chief Engineers of Shipping Board Ships Honored for Efficiency

THE Fuel Conservation Committee of the United States Shipping Board, which was organized about a year ago by Joseph E. Sheedy, vice-president of the Emergency Fleet Corporation, has announced the first list of chief engineers who have shown outstanding efficiency in the operation of Shipping Board vessels during the past six months. At this time it is only possible to include in this list the chief engineers operating vessels out of the Port of New York, but in the future the committee will issue quarterly reports that will include other principal ports.

The fuel bill is the largest item of the operating costs, and it is, therefore, the logical place to help reduce the handicap under which American vessels are laboring in their competition with foreign shipping. The amount of fuel that is burned is under the direct control of the chief engineer, and the Fuel Conservation Committee, much to its gratification, has found that the engineers have appreciated its work of determining how much fuel the numerous types of Shipping Board vessels ought to consume, and are giving their hearty cooperation.

There has been a decided improvement all along the line, not only because the engineers have been given a standard to aim at but also because it is only human for a man to do his best when he knows that some one having authority is taking interest in what he accomplishes. The following honor list includes only those who have shown exceptional ability. There are several chiefs who are close to the mark and there will probably be several new names in the next report.

Honor List

Chief Engineer	Vessel	Operator

Motorship *Twin Ports* Passing Through Locks Near Amsterdam, N. Y., on Maiden Voyage Through New York State Barge Canal

First Diesel Electric Motorship from the Lakes Makes Maiden Trip Through New York State Barge Canal

MANEUVERING with the utmost ease and handling like an old and tried vessel, the Diesel electrically propelled Great Lakes and canal motorship *Twin Ports*, of the Minnesota Atlantic Transit Company completed her maiden voyage between Ashtabula and New York, docking at the latter port on September 20. She carried a bulk cargo of rye and was accompanied through the New York State Barge Canal by a party of engineers and shipping men.

The first trip of the *Twin Ports* followed immediately upon the official trials held at Ashtabula, which came up to and exceeded

every expectation of her designers and builders. The voyage through the Welland Canal, down the Erie Canal and through the Hudson waterway was made without a hitch. A. Miller MacDougall, president of the Atlantic Transit Company, declared the Diesel electric propulsion to be unsurpassed for the class of service and was high in his praise of the vessel's performance.

The *Twin Ports* is a steel electrically driven motorship, designed by Henry Per-ton, of Cleveland, Ohio, and constructed by the Great Lakes Engineering Works, Detroit, Mich., at their Ashtabula, Ohio, plant. The electrical propelling machinery was supplied by the General Electric Company, Schenectady, N. Y.

The principal dimensions are as follows:

Length overall	258 feet
Beam	42 feet
Depth	18 feet
Draft	10 feet
Speed	10 miles
Cargo capacity	2,600 tons
Refrigerated cargo	600 tons

PROPELLING MACHINERY

The propelling machinery consists of two 375 horsepower, 6-cylinder, 4-cycle Diesel engines, built by the Lombard Governor Company, of Ashland, Mass. Each engine is directly connected to a 250-kilowatt generator and operates at a speed of 260 revolutions per minute.

These two main generators work on a common bus bar, so that the two propelling motors are assured of an equal distribution of

power. The current from this bar is supplied to the two propelling motors which are of 250 horsepower. All the motors are operated at a normal speed of 180 revolutions per minute.

NOVEL FEATURES

An unusual feature of the machinery installation is the fact that both main engines are installed with the axis of their crankshafts athwartships instead of longitudinal. Another innovation is the control of these engines which is entirely in the hands of the captain in the pilot house. The engineer on watch has no knowledge of what the captain may be doing. He can, however, note the amount of power being used at any time by looking at the switchboard. In this way the time of announcing the captain's orders to the engine room is saved.

These engines differ from most Diesel designs in that the valve gears which run right across the top of the engines and the piping all stay in place when the pistons are removed. The pistons, as will be surmised, are removed from the bottoms of the engines.

Each engine carries its own air compressor, delivering injection air at about 850 to 900 pounds per square inch. The compressors are directly connected to the main engine and are of the three-stage type. The forced lubricating oil system is also directly driven by means of gears from the main engine.

AUXILIARY ENGINE

There is also installed an auxiliary engine of 60 horsepower which runs at 360 revolutions per minute and which is directly connected to a 40-kilowatt generator. This auxiliary engine, however, is not connected for driving the auxiliaries when the vessel is at sea. This is done by the main engine when under way. The auxiliary power is for port service only, except in the case of emergency.

AUXILIARY MACHINERY

All the auxiliary machinery is driven by motors. In the engine room there is one water circulating pump of the centrifugal type of 7½ horsepower; one general service pump of 20 horsepower of the plunger type which may also be used as a standby as a circulator; one rotary balance pump of 10 horsepower; one lubricating oil pump of the plunger type which is a standby in case the pump directly connected to the engine fails; one fuel oil transfer pump of the plunger type of 3 horsepower; one emergency compressor of the Winton type of 6½ horsepower, and one emergency 5-kilowatt kerosene Winton set.

DECK MACHINERY

All deck machinery is electrically driven, including the steering gear and windlass. The heating is all electric throughout the ship. Maxim silencers for the exhaust gases furnish hot water for the daily supply tanks and for heating the fuel oil in the double bottom.

TRIAL TRIP

On the trial trip, which was held between Ashtabula and Cleveland, a speed of 9.6 miles was obtained, but in deep water, while running down the Hudson river, the vessel made over 10 miles.

Mr. H. Schreck, chief engineer of the Lombard Governor Company, was highly gratified by the performance of the vessel and prophesies that many more of her type will be constructed for the canal in the near future. In the winter months the *Twin Ports* is scheduled to operate in the coastal service between New York, southern ports and the West Indies, carrying refrigerated and other perishable cargoes.

Penn Bridge Company Offers Lowest Price for Construction of Six Steel Barges for Government

AT the opening of tenders by the United States Engineer Office, of Montgomery, Ala., on September 10, for three steel barges 80 feet by 26 feet by 5 feet, and

three barges 60 feet by 22 feet by 4 feet, the Penn Bridge Company, of Beaver Falls, Pa., was low bidder. The prices submitted were as follows:

Name and Address	Amount	Delivery, Days	Barges, Number	Size
Penn Bridge Co., Beaver Falls, Pa.....	\$72,850.00	250	Six	Three 80'x26'x5' Three 60'x22'x4'
Nashville Bridge Co., Nashville, Tenn..	15,485.00 31,990.00 46,925.00 27,480.00 73,900.00	150 170 190 190 240	One Two Three Three Six	80'x26'x4' 80'x26'x4' 80'x26'x4' 60'x22'x4' As above
Charleston Dry Dock & Machine Co., Charleston, S. C.....	16,336.00 31,672.00 48,008.00 28,692.00 76,700.00	240 240 240 180 240	One Two Three Three Six	80'x26'x5' 80'x26'x5' 80'x26'x5' 60'x22'x4' As above
Bethlehem Shipbuilding Corporation, Ltd., 25 Broadway, New York, N. Y.*.....	52,225.00 32,525.00	185 185	Three Three	80'x26'x5' 60'x22'x4'
The Dravo Co., Diamond Bank Bldg., Pittsburgh, Pa.	52,500.00 33,150.00 85,650.00	195 180 195	Three Three Six	80'x26'x5' 60'x22'x4' As above
Midland Bridge Co., Midland, Pa.....	86,000.00	300	Six	Three 80'x26'x5' Three 60'x22'x4'

*If awarded, 6 barges take 235 days to deliver.

198 Steel Vessels of 164,236 Gross Tons Under Construction or Contract for Private Ownership on August 1

ON August 1, 1923, American shipyards were building or under contract to build for private shipowners 198 steel vessels of 164,236 gross tons, compared with 203 steel vessels of 172,301 gross tons on July 1, 1923.

There were 8 wood vessels of 1,004 gross tons building or under contract to build for private shipowners during the same period, compared with 5 wood vessels of 1,004 gross

tons on July 1, 1923. These figures do not include government ships or ships building or contracted for by the United States Shipping Board.

Following is a summary of reports of shipyards to the Bureau of Navigation, Department of Commerce, showing the number and gross tonnage of steel and wood vessels of 100 gross tons and over under construction or contract for private owners on August 1, 1923:

Companies	Steel		Wood	
	Number	Gross tonnage	Number	Gross Tonnage

Two Ferries and Two Barges to Be Built in Connection With New Orleans Terminal Service and Development

THE Algiers Public Service Company, Inc., of New Orleans (Algiers), La., is having plans and specifications prepared for the building of two new catamaran type ferries for service from New Orleans to Algiers, across the Mississippi River. The vessels are to replace the present steamers of similar type, which are to be used at Barracks and Olivier streets after being considerably altered and given a general overhauling.

The proposed new boats are to have a length of 150 feet, beam 65 feet, and will burn oil for fuel. They will be fitted to carry passengers on the upper decks and vehicles on the lower deck and will be in general larger and more modern than their predecessors.

TWO BARGES PLANNED

The same company has issued plans and specifications for two pontoon barges 90 feet long, having a beam of 30 feet and seven feet deep, bids for which were received last month. The vessels are also for use at Barracks and Olivier streets, which terminal is to be a complete new installation on both sides of the river. It will comprise ferry houses, bridges, pontoons, piling supports, hoisting devices, etc.

The Canal street terminals, where the new ferries will be used, will also be a new development, with pontoons, bridges, piling, ferry houses, hoisting devices, etc. The Algiers Public Service Company is building or taking care of the Algiers side of the improvements and the Dock Board is building the New Orleans terminal in conjunction with beautification plans for the head of Canal street. Modern equipment will be used throughout the development.

Contract for Reconditioning U. S. Seagoing Dredge Atlantic Awarded to Morse Dry Dock & Repair Company

THE contract for extensive repairs and reconditioning work on the U. S. seagoing dredge *Atlantic*, has been awarded the Morse Dry Dock & Repair Company of Brooklyn, N. Y., following the opening of bids by the United States Engineer Office, 39 Whitehall Street, New York, on September 12.

The specifications provided for a large amount of various work on the hull and extensive repairs to the engines and the auxiliary machinery. The installation of oil tanks and oil burning equipment with the necessary heaters, pumps, etc., was also provided for. The bids submitted were as follows:

	For all work except Par. 24, 57, 71 and 72.	Par. 67.	Work under 71 and 72.	Par. 71 and 72.	Time for work except Par. 71 and 72.	Time for work except Par. 67.	Per cu. yd. for re-moving mud.	Per lb. for old castings.
Morse	\$41,000	\$3,110		\$35,115	20 days	35 days	\$3.50	.0025
Robins	45,850	2,900		32,900	40 days	40 days	3.50	.005
Tietjen & Lang	47,774	3,010		34,845	42 days	42 days	3.50	.005
W. & A. Fletcher	53,600	4,500		38,500	33 days	45 days	3.25	.003
Staten Island Shipbuilding Co.	53,990	3,470		46,790	30 days	40 days	3.50	.0075
Federal	55,000	5,000		48,000	35 days	48 days	3.25	.004
Bethlehem	81,800	8,700		65,000	100 days	140 days	2.00	.005

Paragraphs 24 dealt with the removal of material in the bins after the dredge was docked; 67 with boilers, fire room and bunker work, material to be furnished by contractor;

71 with the building of two oil tanks, one on each side of the dredge, and 72 with the furnishing and installation of an oil burning equipment.

Reconditioning of Five Army Transports to Replace "502's" Is Planned By Shipping Board

THE conversion and reconditioning of five army transports for the replacement of the "502" ships recently sold by the government to the Dollar Line is under consideration by the Shipping Board. It is understood that preliminary plans are being prepared for the preparation of five of the Hog Island type "B" ships, laid up in the James River, for service as freight steamers on the London route for the United States Lines.

It is believed that the reconditioning work will include the addition of refrigerator spaces for cargo, a general rearrangement of the ships and the possibility of later fitting them to carry a limited number of passengers. The ships are 448 feet long, equipped with geared turbines and reduction gears.

Although official figures were not obtainable, it is thought that the work to be done will involve an expenditure close to \$100,000 for each ship.

Seven "502" Ships Sold by Board to the Dollar Line

CHAIRMAN EDWARD P. FARLEY, of the United States Shipping Board, has announced the sale of seven combination freight and passenger ships, known as the 502 type, to the Dollar Line, whose home office is the Dollar Building, San Francisco. These vessels, the *President*, *Garfield*, *Monroe*, *Adams*, *Van Buren*, *Polk*, *Hayes* and *Harrison*, will be operated in an around-the-world service, starting at San Francisco and touching Japan, China, Philippines, Java, Straits Settlements, Singapore, India, through the Suez, Egypt, Mediterranean ports to New York, thence through the Panama Canal to home. By arrangement with the Board, this service is guaranteed for five years. This will be the first round-the-world service of this kind that has been inaugurated, for while the Dollar Company is maintaining freight boats on this service, there are no other ships now in a continuous service around the world under any flag.

The Shipping Board is of the belief that this service will be of great value to American travelers and merchants, and it will have the full support of the Board in its effort to build up an American merchant marine.

These ships were built by the New York Shipbuilding Company and are of 10,533 gross tons register and 6,195 tons net.

Contract for New Steamer Awarded to Midland Barge Co.

THE Midland Barge Company, Midland, Pa., has received a contract from the Louisville-Cincinnati Packet Company for the construction of a steel hull, side wheel five deck passenger and packet steamer. The vessel is to have an overall length of 291 feet 6 inches; beam molded, 45 feet 6 inches; beam over guards, 83 feet; depth molded, 7 feet 6 inches.

Engines are to be tandem compound, to be built by the Charles Barnes Engine Company, Cincinnati, Ohio, and steam is to be supplied by five boilers to be built by the Acme Boiler Company, Gallipolis, Ohio.

Annual Convention of Atlantic Waterways Association Nov. 13-16

"Get the American waterways in shape for work" will be the motto this year of the Atlantic Deeper Waterways Association, which will hold its sixteenth annual convention in Norfolk, Va., November 13-16, according to Mayor J. Hampton Moore, of Philadelphia, president of the organization, who has issued a call for a big attendance of business delegates.

He urged a representative attendance from the ports and sections whose commercial welfare will be affected by development.

Removal Notice

R. E. Lovekin Corporation will occupy the sixth floor of the Smith Building at the southeast corner of 18th and Market Streets, Philadelphia, Pa., after October 1, 1923.

Norfolk Ready to
Pay \$3,500,000 for
Army Supply Base

NORFOLK, Va., (Special)—The city of Norfolk has agreed to pay \$3,500,000 for the Army Supply Base here, exclusive of the two piers, on condition that it shall be allowed to lease the piers while the government desires to retain title to them and that it shall be permitted to purchase them for \$1,500,000 when the government no longer has need of them. The City has operated the Army Base facilities under lease as a municipal terminal, for about four years. The papers covering the transaction, prepared at a series of conferences between city officials, their counsel, Col. Jennings C. Wise, and members of the Shipping Board, and their attorney, John Nicholson, are ready for signatures.

Though the city desired to purchase both the piers and the shore property, which includes long rows of fireproof warehouses, miscellaneous buildings and fifty miles of tracks, offering the War Department \$5,000,000 for the whole of the property, the plan which has been worked out in the opinion of members of the port commission, is almost as advantageous to the municipality.

The value of the warehouses and railroad yards at the army base is directly dependent upon whether the owner of this property has ownership, or the right to use the two piers. Therefore, the contract for the transfer of the property has been drawn with a view to the protection of the city's interests. It is understood that the city is to receive title to the property on shore as soon as it signs the deed and that another deed, transferring the piers to the city when the government is willing to relinquish them, will be placed in escrow.

The government retains no waterfront, except that occupied by the two piers, and a strip on either side of them the width of half a slip.

Scholarships Awarded by Lloyd's
American Committee

THE quarterly meeting of the American committee of Lloyd's Register of Shipping, held in New York on September 5, was marked by the introduction to the committee of the first four successful candidates to be awarded the scholarships in naval architecture and marine engineering given by the committee.

These scholarships were established in the early part of 1922, one being allotted to the Massachusetts Institute of Technology, Cambridge, Mass., and one to the University of Michigan, Ann Arbor, Mich. Each scholarship has a value of \$500 per annum and is tenable for three years, subject to the satisfactory annual progress of the student. The first two scholarships were awarded in July, 1922, to students of the freshman classes of the above universities, Warner Lombard, of Dorchester, Mass., being awarded the scholarship at the Massachusetts Institute of Technology, and Christopher E. Blaydon of Detroit, Mich., that at the University of Michigan.

This year the committee has awarded the University of Michigan scholarship to Mark J. Ireland, Jr., of East Lansing, Mich., and the Massachusetts Institute of Technology scholarship to R. W. Rogers of Chicago, Ill. These four gentlemen were presented to the American committee of Lloyd's Register of Shipping by Alfred Gilbert Smith, chairman of the society, and president of the New York & Cuba Mail Steamship Com-

American Bridge Company Submits
Lowest Proposal for Construction
of 19 Steel Barges for Government

THE American Bridge Company, Pittsburgh, Pa., with a price of \$54,000 for four barges without cargo boxes and \$215,250 for fifteen barges with cargo boxes, submitted the lowest price for the construction and delivery of nineteen of the boats at the opening of tenders by the United States

Engineer Office, Louisville, Ky., on September 11. The proposed vessels are to have a length of 110 feet; beam, 26 feet; depth 6½ feet.

The prices submitted, upon which no decision has been announced as yet, are as follows:

	No. 1, American Bridge Co., Pittsburgh, Pa.	No. 2, Nashville Bridge Co., Nashville, Tenn.	No. 3, Dravo Contracting Co., Pittsburgh, Pa.	No. 4, Chas. Hegewald Co., New Albany, Ind.	No. 5, Howard Shipyard & Dock Co., Jeffersonville, Ind.	No. 6, Midland Barge Co., Midland, Pa.	No. 7, Penn Bridge Co., Beaver Falls, Pa.	No. 8, Riter-Conley Co., Pittsburgh, Pa.
Regular Proposal—								
4 Steel barges, lump sum.	\$54,000	\$96,160	\$72,800			\$80,000	\$76,240	\$61,120
15 Steel barges, lump sum.	215,250	387,600	287,250			318,000	302,830	243,450
Alternate Proposal No. 1—								
15 Steel barges, lump sum.	215,250	390,600	287,250			318,000	317,830	243,750
Alternate Proposal No. 2—								
4 Steel barges, lump sum.	54,000	96,960	72,800			80,000		61,200
10 Steel barges, lump sum.	143,500	260,400	191,500			212,000		162,500
Alternate Proposal No. 3—								
10 Steel barges, lump sum.	143,500	264,400	194,000			212,000		163,700
Alternate Proposal No. 4—								
4 Steel barges, lump sum.		98,960	74,320			80,000		63,720
5 Steel barges, lump sum.		132,700	97,800			107,000		84,600
Alternate Proposal No. 5—								
5 Steel barges, lump sum.		136,200	100,000					91,650
Alternate Proposal No. 6—								
4 Steel barges, lump sum. *		103,700	76,880	69,990	71,670		83,300	71,720

*If barges are delivered afloat at Ambridge, Pa., sum of \$350 per barge will be deducted from above price.

Todd Yard is Low
Bidder for 6-Barge
Construction Job

THE Tacoma plant of the Todd Shipbuilding Corporation, submitted the lowest bid for the construction of six steel barges at the opening of proposals by the United States Engineer Office, Portland, Ore., on September 7. The Todd figure was \$114,900.

The proposed boats are to have a length of 120 feet, 34 feet beam and a depth of 7 feet 6 inches, delivery to be at Linton, Ore. The tenders were:

Todd (Tacoma)	\$114,900
Smith & Watson Works.....	155,700
Albina Marine Iron Works.....	179,850
Seattle Boiler Works.....	180,000
Penn Bridge Company.....	181,200
W. B. Kyle.....	193,200
Bethlehem S. B. Corporation.....	297,710

Ford to Build Million Dollar
Plant With Docks

It is reported from Louisville, Ky., that Mr. J. L. McPhee, manager of the Louisville Ford Company's assembly plant, has announced that the Ford Company will build a new \$1,000,000 assembly plant on the Ohio River in the suburbs of Louisville. Docks and terminal facilities at this plant will be erected as the Ford Motor Company plans to use the river to a large extent in its shipments.

They were afterwards entertained at luncheon at the Whitehall Club. During the afternoon they visited the White Star Liner *Olympic* and on the following day were shown around the city of New York.

Bids Received
for Six Derricks
at Louisville, Ky.

THE United States Engineer office, Louisville, Ky., received sealed proposals until 2 P. M., central time, September 29, for furnishing and delivering two to six steel derrick boat hulls. The derricks are to include all sheaves, pins, collars, clevises, rollers, boom sheaves, blocks, etc., but not wire rope. The booms are to have a length of 65 feet and the bull wheels will have a diameter of 16 feet.

The proposed hulls are to have a length between perpendiculars of 74 feet 8 inches; beam 34 feet 8 inches; depth at gunwale 5 feet. Delivery is to be made at U. S. Siding, Louisville and Portland Canal, Louisville, Ky. It is estimated that the boats will cost about \$5,000 each.

Proposals Open October 1 for
Marine Boiler, Stack
and Fixtures

Sealed proposals will be received until 11 A. M., October 1, by the United States Engineer Office, Montgomery, Ala., for furnishing one steam boiler, with fixtures, stack, etc., for the U. S. Dredge *Upatoi*, at Columbus, Ga.

The boiler is to be of the Scotch marine, water-back type, designed for a working pressure of 200 pounds, to have not less than 1,200 square feet of effective heating surface and not less than 37 square feet of grate area. The furnace is to be of the Morrison suspension type. The stack to be furnished is to be of suitable diameter, 35 feet in length and supplied in two sections. It is to be built of 14-gage steel.

Shipping Board Owns 1,334 Ships Valued at \$226,733,315; Only 416 Are in Operation or Ready for Delivery

CHAIRMAN EDWARD P. FARLEY, of the Shipping Board, has made public the figures on the merchant fleet owned by the Board showing the number and kind of ships composing the Government fleet, together with their valuation.

The statement, as of September 8, 1923, shows that the Board owns 1,334 ships, the total value of which is \$226,733,315. Of these ships 416 are in operation or ready for spot delivery, with 882 laid up, exclusive of 35 tugs laid up and in operation.

The value of the ships in operation or ready for spot delivery is \$137,311,940; the value of the laid up ships is \$87,906,375. The value of the tugs is \$1,515,000.

The total value of the fleet as of July 1, 1923, was \$227,732,615. Since July 1 the Board has sold six ships at a total sale price of \$999,300.

The following table shows the various classes of vessels in possession of the Board, with their valuation:

Recapitulation of Classification and Valuation of Fleet as a Whole

	Spt or Operating	Laid Up
Cargo	\$81,390,410 (365)	\$75,568,296 (802)
Tankers	8,608,230 (19)	5,558,670 (26)
Refrigerators..	923,300 (2)	3,098,136 (12)
Concrete tank- ers		175,000 (7)
Concrete cargo Class "F" usa- ble		7,000 (2)
Damaged and obsolete		374,773 (5)
Transport (ca- ble)		474,500 (19)
Transport type "B"		25,000 (1)
Passengers ...	46,390,000 (30)	1,225,000 (5)
		1,400,000 (3)
Total	\$137,311,940 (416)	\$87,906,375 (882)

Tug—laid up and operating..	\$1,515,000
Spt or operating.....	\$137,311,940 (416)
Laid up	87,906,375 (882)
Tugs	1,515,000 (36)
	\$226,733,315 (1334)
Sold since July 1.....	999,300 (6)
Total value of fleet as of July 1, 1923	\$227,732,615 (1340)

Company Formed to Manufac- ture Blowers

The Connecticut Blower Corporation, Hartford, Conn., has been incorporated under the laws of Delaware, with a capital of \$250,000. M. E. Keeney is president, C. H. Keeney, treasurer, and C. E. Keeney, secretary.

The new company has taken over the International Blower Company and the Hartford Sheet Metal Works. The products manufactured and installed are of a large variety, such as blowers and exhaust fans, blower systems of all kinds, dust collecting systems, exhaust systems, ventilating systems, etc.

New Linde Warehouse Established

A new warehouse has been established by The Linde Air Products Company at the B. & M. Wharf, Portland, Maine, in order to give even better service to users of Linde Oxygen and Prest-O-Lite Acetylene in the state of Maine. S. W. Jordan, 11 Exchange street, will be in charge of distribution.

Propeller Club to Act as Entertain- ment Committee for Marine Congress

THE Propeller Club of the Port of New York has accepted the invitation of the American Marine Association to act as the official Marine Congress Entertainment Committee. The Congress is to be held at the Waldorf-Astoria Hotel, November 5-10, and the Entertainment Committee will function for the benefit of the Marine Exposition, as well as the Congress, both events taking place during the same week.

In this connection, the Propeller Club has appointed a Central Committee, the members of which will be chairmen of sub-committees, as follows: W. Z. Gardner, chairman; Norris R. Sibley, hotel committee; Chester Roe, transportation committee; Nelson S. Tobey, ship inspections committee; E. M. Roberts, exposition committee; H. W. Parsons, entertainment committee. They will assist the delegates in obtaining hotel reservations, best methods of transportation, sight seeing tours around the world's greatest port, inspections of the various types of ships, including passenger, freight and war vessels, which will be placed at their disposal during Marine Week.

Marine Congress
Official Badge

Over a Million and a Half to Be Spent in San Francisco Bay

THE sum of \$1,674,000 will be expended in the near future on improvements to harbors and channels around San Francisco Bay by the Federal Government, according to an announcement by Col. Herbert Deakney, U. S. Army Engineer Corps.

The main channel to San Francisco Bay is 36 feet at its greatest depth, and at some places, 30 feet. The plan of the army engineers is to make a 43 foot depth in all places and a width of 2,000 feet.

Radio Equipment for Nantucket Shoals Lightship

Commissioner of Lighthouses G. R. Putnam has informed the Philadelphia Maritime Exchange that the new Nantucket Shoals light vessel will be equipped with radio fog signaling apparatus and that the candlepower of the light will be increased to three thousand.

The radio signal will consist of a radio broadcast of four dashes every thirty seconds, followed by a silent period of twenty-five seconds, the signal to be transmitted on three hundred kilo cycle frequency, which is a one-thousand meter radio wave.

Except as stated, the new vessel will have the same characteristics and signals as the old vessel.

TRADE PUBLICATIONS

MONEL METAL.—A catalog on the uses of monel metal has been received from G. and J. Weir, Ltd., Cathcart, Glasgow. Among other things, this catalog calls special attention to diagrams showing the strength at high temperatures on monel and various other metals. Another special point brought out in the book is the resistance of monel metal to corrosion and its uses in a variety of industries.

CLEANING BOILER TUBES.—In a pamphlet recently issued, the Heine Boiler Company, of St. Louis, states that tests have shown that one-fiftieth of an inch of scale deposited on a steel plate will reduce the rate of heat conduction 60 to 75 percent. The means provided in Heine boilers for maintaining clean tubes are described in this pamphlet, and details of the Bayer soot blower, which is furnished with every Heine boiler, are included.

THERMIT RAIL WELDING.—The Metal & Thermit Corporation, New York, has issued a new thermit rail welding pamphlet, which brings up to date the whole subject of thermit rail welding to cover the many recent improvements in economy and efficiency.

HISTORY OF THE NIPPON YUSEN KAISHA.—The Nippon Yusen Kaisha, Tokyo, Japan, which came into existence in 1885 as a result of the amalgamation of two Japanese shipping concerns, has presented in booklet form a short but complete history of the line which is to a great extent the history of the shipping industry of Japan. This book is written in English for special distribution in this country and England. It offers an excellent means of becoming acquainted with the progress of the industry in the Eastern countries.

PORTABLE ELECTRIC TOOLS.—A miniature catalog sent out by the Hisey-Wolf Machine Company, Cincinnati, Ohio, briefly describes the complete line (112 different types and sizes of tools) of Hisey electric products. This book has been prepared principally for dealers and agents who know the value or necessity of placing complete condensed practical information in the hands of all customers and prospects.

ELECTRICAL FIXTURES.—Details of switches and plug receptacle housings and other types of conduits in a great variety of forms for special usage in both land and marine practice are listed in an illustrated bulletin sent out by the Crouse-Hinds Company, Syracuse, N. Y. QE housings are made to in close snap switches, key switches, attachment plug receptacles and 125, 250 and 600 volt Crouse-Hinds plug receptacles. Further information relative to various combinations of bodies and housings will be furnished upon request by the company.

COMMUTATOR TRUING DEVICE.—Several leaflets illustrating and describing the Jordan commutator truing device have been made available by Jordan Brothers, Inc., 74 Beekman street, New York. It is stated that this device supplies the only correct method of grinding commutators or slip rings in their own bearings, leaving them true and smooth. The device grinds the commutator through the medium of an abrasive wheel, is applied quickly and easily adjusted without special skill required of the operator and is used equally well on flint mica or under-cut commutators without bridging copper across the mica. No interruption of service is necessary, for machine may carry their load while being ground.

Foreign Shipping and Shipbuilding Activities

British Shipping Exhibition Repays Visit to Olympia

By James Swan*

LONDON, Eng. (Special).—The Shipping Exhibition now being held at the Olympia, London, is full of interest for all who are even remotely connected with the building and operation of ships. One is at once struck by the neatness and good arrangement of the various exhibits, as well as the very large range of subjects covered by them.

NUMEROUS AUXILIARIES EXHIBITED

The exhibit of auxiliary machinery of various kinds is especially comprehensive, and one is particularly impressed by the old and substantial character of the various machines. The British surely have earned to put material "where it does most good."

In this class were particularly noted the Worthington Pump Company, James Howden and Company, Wallsend Slipway and Engineering Company (oil burning equipment), The Williams-Janney hydraulic speed gear (similar to the American Waterbury speed gear) and the Kirkaldy evaporators, etc.

Other interesting exhibits deserving notice were Wales and Dove's bitumastic enamel, etc., the Parsons Turbine Company, Welinavit, Brown-Lennox Chain Company, Perry gyro compass and a large number of electric welding machines of various types, as well as wireless telegraphs and similar apparatus.

These are a few of the exhibits which were especially noticed—there are dozens of others of equal interest, but too numerous to mention in a passing notice.

MOTORBOAT SHOW IN THE ANNEX

In the annex, a new building, there is a large collection of motorboats and gasoline (or petrol) engines. Some of the hulls are most beautifully constructed and the large exhibit of engines by Thornycroft is particularly fine.

Taken altogether, the exhibition is most decidedly worth visiting, and the substantial and wholesome character of almost everything shown leaves one with a good impression of the character of materials and outfits which enter into the construction of British vessels.

*Editor of MARINE ENGINEERING AND SHIPPING

Australian Government Shipping Venture Costly

THE financial statement of the Australian Commonwealth's fleet of merchant ships, as summarized by the Transportation Division of the Department of Commerce, gives the present book value of the fleet as £12,766,588, but the current market appraisal of the fleet is put at £4,718,150. The account of Government operation shows a net loss of £493,271. In addition, the Government also lost £2,300,000 on its contract for 14 American wooden steamers, thus the total losses on the Australian Government's venture in shipbuilding and shipowning are close to £11,000,000.

Financial Aid for Shipowners Planned in France—Eight New Liners Being Built

By Our Paris Correspondent

A QUESTION which is at present stirring much interest both in shipping and parliamentary circles is that relative to the institution of a private banking company which should make advances of money to shipowners in order to enable them to hold out until the prevailing difficulties in shipping affairs have disappeared. The necessity for such an organization—called the Credit Maritime—has been echoed for months in French papers.

Several interesting developments have taken place in that respect in the course of the last few weeks. When the Government had ascertained that the proposed organization would meet with the unanimous approval of all concerned in shipowning in this country, they appointed a committee, the Commission Interministerielle, which was intrusted with the task of investigating the question and making suggestions towards the realization of the scheme. That committee has recently issued its report.

The most important innovation to be pointed out in connection with the program of the Credit Maritime lies in the fact that not only the real value of the vessels owned by the firm concerned should be taken as security for loans made, but also the personal guarantee of that firm; that is to say, its financial and traffic prospects, the conditions of its management, the efficiency of its

fleet, etc., all of which are considerations which could not be taken into account as securities in respect of loans made on mortgages. The main question now is the constitution of the initial capital of the undertaking.

MESSAGERIES MARITIMES BUILDING EIGHT PASSENGER VESSELS

The Messageries Maritimes, the big French steamship company which is running regular services between France, the Far East, Madagascar and the Mediterranean countries, has just decided on the names which are to be given to the new vessels under construction to its account. It is noteworthy in passing that this company has the largest building program in France, the reason being that the firm has accepted the control of the Government in exchange for a full financial support.

At present this company has no less than 8 passenger vessels under construction to its account. The *Aramis*, of 20,300 tons displacement, is being completed at the yards of the Chantiers de la Gironde at Bordeaux. Her propelling machinery consists of 2 steam turbines of the Schneider-Zoelly type, each driving one propeller shaft through double reduction gearing, the total power developed being about 8,000 horsepower. The same yard is also building a sister ship which is to be named *D'Artaignan*.

To the account of the Messageries Maritimes, also, there is under construction at the yards of the Société Provençale de Constructions Navales at La Ciotat, near Toulon, three passenger vessels. Two of small size (the *Champollion* and the *Mariette*) will be placed in service on the Mediterranean lines of the company, while the third one, the *Leconte de Lisle*, of 15,100 tons displacement, will be run on the Indian Ocean line. A sister ship to the *Leconte de Lisle*, which is to be named *Explorateur Granddier*, is under construction at the yards of the Chantiers et Ateliers de Saint-Nazaire-Penhoet.

In addition to these 6 vessels, the Messageries Maritimes has under construction in German yards two passenger vessels of the *Aramis* type, which will be run with the *Aramis* and the *D'Artaignan* on the Marseilles-China line. They have been ordered from German yards in accordance with the Versailles Treaty.

installed would be 600 francs for each twenty-four-hour period, the price of the oil today being 400 francs per ton. This is the price quoted for the fishing shipowners, who, it is estimated, would buy quantities of 50 or 100 tons at a time. This price is quoted with the Franco-American rate of exchange at 14.96 francs to the dollar.

With coal at 152 francs per ton, the steam-propelled fishing vessel of 500 tons horsepower consumes daily about 10 tons. This calls for an outlay by the owner of 1,520 francs daily for coal alone. And with a bunker capacity of 300 tons, the vessel can remain at sea for only thirty days.

First Heavy Oil Motor Vessel for French Fishing Fleets

A STEP which portends a complete revolution of the French fishing industry and the opening of an important market for internal combustion, heavy oil motors, of the Diesel or semi-Diesel type, is being taken at Boulogne-sur-Mer, where the first installation of this kind is being made on one of the largest trawlers of the fishing fleet, according to a special report to the Department of Commerce. The event is heralded as the death signal for the coal-burning steam type of vessel, which is now exclusively employed in the French fishing industry.

Having experienced two years of discouraging losses—the receipts of 1921 and 1922 having been insufficient to meet the expenses of operation—the owners of the fishing fleet vessels find themselves forced to discover a means whereby their ships may put to sea and return without spending too much money for fuel. This situation, which becomes more acute daily, seems bound to aid in the development and installation of the new system of motor propulsion on the vessels of the fleet.

The motor being installed is a "Chaléassière" of 500 horsepower, which burns mazout. It is a simplified type of Diesel, and it is estimated that its maximum consumption will be one and one-half tons of mazout for each twenty-four hours.

Predicating estimates on the consumption of one and one-half tons of mazout a day, the cost of operation of the motor being

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPBUILDING AND REPAIRS

Engine Repairs, Savannah, Ga.—The Shipping Board steamer Cripple Creek is at Savannah for repairs to her engines.

Steamer Drydocked, Cleveland, O.—Steamer W. H. Donner, damaged by grounding recently, has been placed in drydock at Cleveland for repairs.

Overhauling of Steamer, San Pedro, Cal.—The steamer American, damaged to the extent of \$210,000 by fire at sea, has been taken to San Pedro for overhauling.

Vessels Drydocked, Chester, Pa.—The steamships Sunoil and J. N. Pew, of the Sun Company, have been drydocked for thorough overhauling at the Chester plant.

Ship Work, Mobile, Ala.—The Alabama Dry Dock and Shipbuilding Company, Mobile, Ala., is completing repairs to the steamship Normania and also the Shenandoah.

Damaged Steamer Repairs, Cleveland, O.—The damaged steamer J. S. Ashley, which recently grounded on Crab Island shoal, Great Lakes, has been taken to Cleveland for repairs.

Ferry Repairs, Jacksonville, Fla.—The ferryboat Dural, which plies between Jacksonville and South Jacksonville, went to the Gibbs drydock recently for repairs to a broken propeller shaft.

Japanese Steamer Drydocked, Portland, Ore.—The Japanese steamer Yonan Maru was recently taken to Portland for drydocking and repairs after having grounded at the mouth of the Columbia River.

Diesel Engine Installations, Pacific Coast.—A 110-horsepower Diesel engine is being installed in the motorship Sudan for the Daniel Contracting Company by the Pacific Diesel Engine Company, of Oakland, Cal.

Hull Damage Repairs, Beaumont, Tex.—Vogemann-Goudriann Company's steamer Deutschfeld is at Beaumont to have her hull, which was damaged badly when it struck a submerged anchor in that harbor, repaired.

Ferryboat Launched, Wilmington, Del.—The Pusey & Jones shipyard in Wilmington has launched the ferryboat Ocean City, the second all-steel ferryboat built this summer for the Philadelphia and Reading Railway.

Tanker at Navy Yard, Norfolk.—The naval tanker U. S. S. Trinity, which recently sailed from Baytown, Tex., for Hampton Roads with a cargo of oil, has been taken to the navy yard for drydocking and repairs.

Miscellaneous Repairs, Chester, Pa.—The Sun Shipbuilding and Drydock Company, of Chester, Pa., has been awarded the contracts for miscellaneous repairs and painting the steamships Hesporos and Fredness.

Miscellaneous Work, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation, San Francisco, has been awarded the contract for making repairs to stern, frame and bottoms of the American Hawaiian freighter Dakotan.

Steamer Docked, Baltimore, Md.—The steamer Robin Adair, operated by Norton, Lilly Company, on their west coast route, was drydocked by the Maryland Dry Dock Company for attention previous to loading for the west coast.

Engine Room Repairs, Mobile, Ala.—The steamship Stavangeren is at the yards of the Alabama Dry Dock and Shipbuilding Company for engine room repairs and also to have 100 grate bars, cast in the yard's foundry, installed.

Contract Awarded, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation, with a price of \$51,240 and twenty-eight days (low bidder), received the contract for generally overhauling the United States transport Thomas.

Towboat Awarded, Marietta, O.—The Marietta Manufacturing Company of Marietta, O., has been awarded a contract for a towboat, 135 feet by 30 feet, for the Vesta Coal Company, of Pittsburgh. The boat will be for use on the Ohio river.

Shipyard Activities, West Coast.—The Shipping Board vessel West Mahwah is at the Hanlon yards for a new stern frame; bids have been tendered for the reconditioning of the steamers Castletown and Castlepoint, by the McCormick Steamship Line.

Bids Rejected, West Coast.—Bids submitted for repairs on the steamer West Carmago, by California shipyard companies, have been rejected. The prices submitted were: Moore, \$1,176; Hanlon Drydock Co., \$1,181.50, and the Bethlehem yard, \$1,186.50.

Repainting, etc., Los Angeles, Cal.—The liner Dorothy Alexander has been shifted to the yard of the Los Angeles Shipbuilding and Drydock Company for repainting and minor overhauling. The Ruth Alexander has also been taken to the same yard for repairs.

Work at Charleston Yard.—The Shipping Board steamship Western Wave, one of the idle fleet in the Ashley river, has been removed to the Charleston Drydock & Machine Company works for overhauling. The dredge Savannah, which is engaged in harbor work, went to the same yard for numerous repairs.

Cramp Shipyard Activities, Philadelphia, Pa.—The Cramp Shipbuilding and Drydock Company has completed repairs on the Black Diamond Steamship Company's steamship Anaconda and is now making miscellaneous repairs to the United Fruit Company's steamship Runa.

Barge Contract, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company, of Mobile, has received a contract for the construction of three steel barges for the Tennessee Coal & Iron Company, a subsidiary of the U. S. Steel Corporation. Work will be started in the near future.

Steel Boom Contract.—The contract for two steel booms, bids for which were opened by the U. S. Engineer Office, Louisville, Ky., on August 27, has been awarded to the Clyde Iron Works, Duluth, Minn., at a price of \$1,580, delivery to be made in 50 days. Ten bids were received, ranging up to \$3,300.

Low Bidder, San Francisco, Cal.—At the opening of tenders for repairs to the Pacific Mail liner Colombia, the General Engineering Company was low bidder for the engine work on the vessel, with a price of \$433. The same company was also low bidder on repairs to the Pacific Mail steamer Corinto.

Todd Equipment on Vessel, Newport News, Va.—The Newport News Shipbuilding and Dry Dock Company, at whose plant in Virginia the President Buchanan is being reconditioned for the Shipping Board, has awarded a contract to the Todd Shipyards Corporation for the installation of Todd burners, fronts and equipment.

Repairs Bids, New York.—The Morse Dry Dock & Repair Company was the low bidder for general repair work on the steamship Luceric, when tenders were opened by Holder, Weir & Boyd, on September 4. The prices were: Morse, \$1,015; Alderton, \$1,100; Staten Island Shipbuilding Company, \$1,122; Robins, \$1,280, and New York Harbor, \$1,740.

Cleaning and Painting, Portland, Ore.—The steamer West Cayote, operated by the Columbia-Pacific Shipping Company in the oriental service for the Shipping Board, has been placed on the St. Johns drydock plant of the Port of Portland,

for cleaning and painting her hull. The steamer West Kader is also on the same docks for voyage repairs.

Will Remodel Tug, Jacksonville, Fla.—Announcement is made by Captain A. B. Potter, of the Jacksonville Forwarding Company, that the tug General D. B. Stanley has been purchased from Norfolk Shipping interests and that the steamer would probably be remodelled. She has a length of 110 feet and is equipped with about 600-horsepower engines.

Shipyard Activities, West Coast.—The Bethlehem Shipbuilding Corporation has been awarded the following work: Steamer West Sequana, of Struthers & Barry fleet, for general overhauling; tanker L. Placencia, repairs to damaged bottom. The company has completed the work on the tanker Job D. Archbold, which consisted of replacing and repairing plates damaged in grounding.

Tug Launched, Portland, Ore.—The tug James W., Diesel driven, to join the Shaver Transportation Company's line of towboats, was launched recently from the plant of the Portland Shipbuilding Company. She has a tunnel hull 90 feet long, 22 feet beam, and depth of five feet. A 300-horsepower Atlas Imperial engine has been installed. The company expects to use her in harbor work.

Low Bidder for Work, Los Angeles, Cal.—At the opening of bids by the Shipping Board for removing turbines and installing reciprocating engines in its vessel Miskianza, the Los Angeles Shipbuilding and Drydock Company was low bidder at \$109,820. The other bids were: Bethlehem Shipbuilding Corporation, \$113,185; Moore Drydock Company, \$113,375, and the United Engineering Works, with a bid of \$123,642.

Repairs at Moore Yard, Oakland, Cal.—The Moore Drydock Company has received the contract for repairs to the hull of the Norwegian tanker So Joaquin, owned by Wilhelm Wilhemson, but under charter to the Union Coal Company. The damage was caused by grounding some time ago. The contract was awarded at a price of \$18,735 and ten days, the Bethlehem Shipbuilding Corporation tendering a bid of \$19,875 and ten days. Besides the work, eight new plates will be installed. The same yard is storing a new tailshaft for emergency services in the tanker Sylvan Arrow.

Ship Work, Oakland, Cal.—The Hanlon Shipyard has showed marked activity recently and has received the following vessels for miscellaneous repairs: steamer Nome City, drydocking and general overhauling, including the installation of a new lead sleeve, new tailshaft, bronze wheel, and renewal of her stem and canvassing of her deck lumber carrier Mukilteo, motorship Lassen, steamer schooner Horace X. Baxter, steamer Northland lightship No. 83, ship Monongahela, steamer Vinland and barkentine Monitor for drydocking and general overhauling. To have her decks calked and for the installation of new foremast and bowsprit, the barkentine Mary Winkelman is on drydock at the same yards.

Toss of Coin Decides Contract, San Francisco, Cal.—A contract involving more than \$3,000 was settled between two officials of San Francisco shipyard firms by the toss of a coin. The contract called for work on the United States transport Grant. When the tenders were received it was found that there was a misunderstanding in the amount of work to be covered in the bid, the two companies bidding on the full work being the General Engineering Company and the United Engineering Company. The work on the transport had to be finished as quickly as possible and therefore Frank Fox, chief engineer for the General Engineering Company, called up Arnes, of the United Engineering Works, who suggested that a coin be tossed with the United Engineering Company. The half-dollars were flipped with the result that the United Engineering Works won.

PORT IMPROVEMENTS

Harbor Improvements, Berkeley, Cal.—Alameda company plans election to vote on \$50,000-\$100,000 bonds for harbor improvements.

Elevator, Valley View, Tex.—Whaley Mill & Elevator Company is having plans prepared for an elevator, the cost of which will exceed \$60,000.

Seawall and Yacht Basin, Sarasota, Fla.—H. F. Atkinson and associates, Miami, plan seawall and yacht basin at Sarasota to cost \$100,000. Engineer not announced.

Pier, Philadelphia, Pa.—Department of Wharves, Docks & Ferries awarded the contract for completing Porter Street Pier #4 to Snare Corporation, 324 Chestnut Street. \$500,000.

River Terminal, Cincinnati, Ohio.—Cincinnati River-Rail Transfer Company, Front and Harriet streets, plans river freight terminal, 50,000 tons' capacity. \$50,000-\$75,000.

Wharf, Pembroke, Ont.—The Department of Public Works, Parliament Building, Ottawa, will soon let bids for a wharf to cost \$125,000. K. M. Ameron, acting chief engineer.

Levee, Sacramento, Cal.—The contract for the removal of Y street levee, 144,744 cubic yards earth excavation, has been awarded to Byrne, Yost & Reister, 2512 N street. \$60,049.

Wharf, Harpor, B. C.—Sealed proposals will be received by R. C. Desrochers, Secretary of the Department of Public Works, Ottawa, until October for a floating wharf at Harpor.

Wharf, Sorel, Que.—Bids were received on September 4 by R. C. Desrochers, secretary, Department of Public Works, Ottawa, Ont., for reconstructing concrete high level wharf here.

Dam on Colorado River, Bronte, Tex.—Coke Run's Water Improvement District 1 plans dam on Colorado River, ditches, laterals, etc. \$4,500,000. \$5,000,000. C. C. Holder, Bronte, engineer.

Grain Elevator, Chippewa Falls, Wis.—Farmers Produce Company, c/o F. W. Anderson, mgr., 15 1st Central street, will build 2-story, brick, plain foundation by day labor. \$40,000. Private plans.

Dredging, Los Angeles, Cal.—Board of Harbor Commissioners awarded the contract for dredging 0,000 cubic yards fronting wharves to the United Dredging Company, Central Building. \$0.244 per cubic yard.

Dredging, Newport, Cal.—Parkinson Syndicate interests have awarded the contract for dredging channel in vicinity of county turning basin to Los Angeles Dredging Company, Seaside Park, Long beach, \$500,000.

Bids for Canal, Port Colborne, Ont.—Dominion Department of Railways & Canals, Parliament Buildings, Ottawa, will soon take bids for Port Colborne section of Welland Canal. \$10,000. W. Bowden, chief engineer.

Hydraulic Dredging, Port Arthur, Ont.—Dominion Canada, Department of Public Works, Parliament Buildings, Ottawa, awarded the contract for hydraulic dredging in Port Arthur harbor to Canadian Dredging Company, Midland. \$246,920.

Breakwater, Toronto, Ont.—The Department of Public Works, Parliament Buildings, Ottawa, Ont., awarded the contract for 4,440 lineal feet of concrete breakwater on the foundation, Toronto, to Miller & Sons, Lumsden Building. \$1,030,000.

Dyke, New Westminster, B. C.—South Westminster Dyking Commissioners, Cloverdale, awarded contract for a 4½-mile earth dyke along Fraser river, opposite New Westminster, to A. B. Palmer Company, 736 Granville Street, Vancouver. \$1,000.

Retaining Walls, etc., Ohio.—P. R. Murray, director of Public Works, Hartman Building, Columbus, will soon take bids for repairs to concrete and masonry walls, also building new retaining walls, at Lake Erie in Fairfield and Licking Counties. \$1,000.

Dikes, Levee Work, etc., Shreveport, La.—The city of Shreveport is having preliminary plans and surveys made for reinforced-concrete dikes, dikes and levee work. \$400,000 to \$450,000. E. Smith, Railway Exchange Building, St. Louis, engineer.

Bids Rejected, Clarksdale, Miss.—The Board of Levee Commissioners, Yazoo, Mississippi Delta, rejected bids for enlarging 5-mile Ward Lake levee containing 10,000 cubic yards of topping, 75,000 cubic yards of barquette enlargement. W. L. Head, Clarksdale, engineer.

Canals, etc., Newport, Ark.—Cache River Drainage District is making plans for drainage ditches, canals, etc., in Jackson and Poinsett Counties. \$1,000,000. Morgan Engineering Company, Goodwin Inst., Memphis, Tenn., and Bowman Engineering Company, Newport, engineers.

Wharf and Warehouse, New Orleans, La.—Board of Port Commissioners, New Court Building, is having plans prepared for a substructure and superstructure concrete wharf, pile foundation, also one-story steel and metal warehouse, 400 to 1,600 feet long, 150 feet wide. \$500,000.

Wharves, Houston, Tex.—The contract for 1,720 feet of wharves has been awarded by the Harris County Navigation District, in three sections, as follows, to Doultt & Williams, Carter Building: reinforced-concrete structure, concrete piling, \$669,000, and timber piling, \$94,000.

Levee, Yazoo City, Miss.—The Clark Construction Company, of Memphis, Tenn., has been awarded a contract by the Rocky Bayou Levee District for a levee on the east bank of Yazoo River, north bank O'Neal's Creek and south bank of Short Creek, 2 canals, etc., at a price of \$150,000.

Cresosoting Lumber, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, at their office, Suite 200, New Orleans Court Building, on September 6, for cresosoting of second hand lumber furnished by the Board. Requisition E. D. 13912.

Coal Pier Under Way, Norfolk, Va.—The construction of steel framing of the new \$3,000,000 coal pier of the Virginian Railway at its Sewells Point has begun, the foundation having been completed. The contract for the steel framing has been placed with the Bethlehem Steel Company.

Contract Awarded, Chico, Cal.—Butte Creek Drainage District awarded the contract for cleaning out Butte Creek to California Dredging Company, Hobart Building, San Francisco. 80,000 yards excavation in outlet drains at \$0.20 per yard and 20,000 yards excavation in drainage canal, \$0.25.

Excavation, Riverhead, N. Y.—Bids were received on September 27 by the Salt Water Bays Commission at the office of the State Engineer and Surveyor, Telephone Building, Albany, for excavating channel connecting Moriches, Quantuck, Shinnecock and Peconic Bays, Suffolk County. D. B. LaDu, chairman.

Wharf Extension, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Court Building, on September 13, for clearing the site for an extension of the Poland Street Wharf on the site of the burned Army Supply Base Wharf. J. H. Walsh, general manager. Requisition E. D. 13789.

Grain Elevator, Houston, Tex.—Harris County Navigation District is having plans prepared for a concrete grain elevator, 900-foot frontage on the ship channel, headhouse, tank storage and grain carriers, initial capacity 1,000,000 bushels, ultimately 6,000,000 bushels. \$1,000,000. E. A. Tucker, Court House, engineer. J. Metcalf & Company, 108 South La Salle Street, Chicago, consulting engineer.

GOVERNMENT WORK

Generators, etc., Washington, D. C.—U. S. Engineer rejected bids for dredging in Scuppernong River.

Breakwater Gulfport, Miss.—U. S. Engineer plans 1,400-foot breakwater at ship basin here. E. North, U. S. E. C., Mobile, Ala., engineer in charge.

Dredging, Honolulu, H. T.—Specification 4891—The Bureau of Yards and Docks, Navy Department, Washington, D. C., plans dredging at Naval Wharf here.

Steel Barges, Portland, Ore.—Sealed proposals were received by the United States Engineer Office, 2nd District, Portland, Ore., on September 7, for six, 120-foot by 34 feet by 7 feet 6 inches, steel barges.

Lock, Pittsburgh, Pa.—Sealed proposals were received on August 23 at the U. S. Engineer Office, Pittsburgh, for constructing Lock 7, Monongahela River.

Levee, Kennett, Mo.—St. Francis Levee District plans rebuilding 12-mile levee, 1,000,000 cubic yards dry earth excavation. J. D. Mitchell, Puxico, engineer.

Dredging, Galveston, Tex.—U. S. Engineer, Galveston, awarded the contract for dredging in Texas City Channel to J. Jacobson, 2311½ Avenue C, \$24,780.

Dredging, Boston, Mass.—Sealed proposals were received on August 30, at the office of the U. S. Engineer, Custom House, for dredging in Beverly Harbor.

Dredging, Oakland, Cal.—The U. S. Engineer Office, San Francisco, Cal., received sealed proposals on September 6, 1923, for dredging in Oakland Harbor, Cal.

Rock Removal, Seattle, Wash.—Sealed proposals were received on September 1, 1923, for rock removal in Willapa River, Wash., by the U. S. Engineer Office.

Dredging, Baltimore, Md.—Sealed proposals were received by U. S. Engineer Office, on August 13, for dredging 2,584,700 cubic yards from entrance of channel, here.

Dredging, Petaluma Creek, Cal.—Sealed proposals were received by the U. S. Engineer Office, San Francisco, Cal., on August 30, for dredging in Petaluma Creek, Cal.

Dredging, Port Isabel, Tex.—The State and Federal Government has awarded the contract for dredging Port Isabel Channel to an 18-foot depth, to J. Jacobson, Galveston. \$314,000.

Riprap Stone, Baltimore, Md.—Bids were received on August 15 by the Superintendent of Lighthouses for furnishing and placing 2,500 tons of riprap stone at Lighthouse Stations, 5th District.

Breakwater, Marquette, Mich.—U. S. Engineer, Custom House, Duluth, Minn., awarded the contract for repairs to breakwater at Marquette to Tidouche Company, Detour, Mich., at \$62,379.

Stone, Harbor Beach, Mich.—U. S. Engineer 337 Federal Building, Detroit, received no bids on August 16 for furnishing and placing 10,000 tons of stone on breakwater here. Will readvertise.

Dredging, New York, N. Y.—Sealed proposals were received on August 9 at the U. S. Engineer Office, 616 Army Building, for dredging and rock removal in Area 2, New York and New Jersey Channels.

Harbor Improvements, Charlotte Harbor, Fla.—The War Department has announced an allotment for river and harbor maintenance and improvement work, including \$20,000 for Charlotte Harbor, Fla.

Bulkhead, Far Rockaway, N. Y.—Atlantic Beach Associates, Inc., plans 1,500 feet of bulkhead, on Far Rockaway Bay. J. R. Spelman, 405 Lexington avenue, New York, consulting and supervising engineer.

Dredging, Far Rockaway, N. Y.—Atlantic Beach Associates, Inc., plans the dredging of 600,000 cubic yard sand fill. J. R. Spelman, 405 Lexington avenue, New York City, consulting and supervising engineer.

Widening Channel, Detroit, Mich.—J. B. Breyman, 2052 Robinwood avenue, Toledo, Ohio, was awarded the contract for widening Livingston Channel, Detroit River, by U. S. Engineer Office, \$293,780.

Removal of Wreck, Beaufort, N. C.—Sealed proposals, in duplicate, were received at the U. S. Engineer Office, Wilmington, N. C., on August 24, for removing wreck of tug Jugo from the ocean bar at Beaufort Inlet, N. C.

Contract Awarded, Baltimore, Md.—U. S. Engineer Office awarded the contract for dredging in Queenstown Harbor, Md., to Calkins Dredging Company, Inc., 604 Bankers Trust Building, Norfolk, Va., at a price of \$5,564.

Removal of Pile Protection, Chicago, Ill.—U. S. Engineer, 537 South Dearborn street, awarded the contract for removal of pile protection in harbor here, to Great Lakes Dredge & Dock Company, 104 South Michigan avenue. \$8,555.

Levees, etc., Wisconsin.—State Legislature has appropriated \$50,000 to strengthen and rebuild levees and dams on Fox and Wisconsin Rivers, Fond du Lac and Winnebago Counties. J. D. Mack, State Capitol, Madison, engineer.

Steel Derrick Boat Hull, Mobile, Ala.—Sealed proposals were received by the U. S. Engineer Office, on August 6, 1923, for furnishing and delivering one steel derrick boat hull, length 80 feet, beam 34 feet, molded depth 5 feet.

Centrifugal Pump, Louisville, Ky.—The U. S. Engineer Office, Louisville, Ky., opened bids August 13 for one two-stage, 6-inch, vertical centrifugal pump, to be installed at the power house at Louisville and Portland Canal, Louisville, Ky.

Breakwater, Alpena, Mich.—U. S. Engineer, 337 Federal Building, Detroit, awarded the contract for furnishing and placing 11,700-ton core stone and 10,300-ton armor stone for rubble mound breakwater, Alpena, to T. L. Durocher Company, Detroit. \$76,340.

Construction of Superstructure, Ludington, Mich.—U. S. Engineer Office, Milwaukee, Wis., received sealed proposals on August 28 for removing stone-filled timber superstructure and constructing concrete superstructure on North Breakwater at Ludington, Mich.

Pump, Louisville, Ky.—U. S. Engineer, Post Office Box 72, awarded the contract for one vertical centrifugal pump to deliver 7,000 gallons per minute against head of 25 feet, complete with motor base, etc., to Morris Machine Works, Baldwinsville, N. Y. \$1,210.

Bids Rejected, New York, N. Y.—J. H. Delaney, Commissioner of Docks, Pier "A," North River, has rejected bids on Item 4, for dredging at street cleaning dumps in Boroughs of Manhattan and Brooklyn; also received no bids on Item 2. Will re-advertise.

Dredging, New Orleans, La.—The contract for dredging five miles in the Calcasieu-Sabine Section of the Intracoastal Waterway, 998,000 cubic yards excavation, has been awarded by the U. S. Engineer Office, 329 Custom House, to H. Reynolds, Maison Blanche Building, at a price of \$128,836.

Excavation, Delaware.—The contract for completing, widening and dredging Chesapeake and Delaware Canal, creating new entrance from Delaware Bay and improving entrance at Chesapeake Bay, Delaware and Maryland, 6,000,000 cubic yards excavation, to Atlantic, Gulf and Pacific Company, 13 Park Row, New York City, Sections A and D, \$740,688; Arundel Corporation, Pier 2, Pratt street, Baltimore, Md., Section B, \$257,359, by the United States Engineer Office, Wilmington, Del.

SHIPPING DEVELOPMENTS

United American Lines.—It is reported from abroad that the passenger steamship *Cleveland*, formerly the *King Alexander* and recently acquired by the Harriman interests for the United American Lines, will sail from Hamburg for New York with a full passenger list on October 23. The ship is being converted into a cabin class steamer at the Blohm & Voss shipyard.

River Transit Company.—Freight carrying on the Mississippi between Topeka, Kan., and St. Paul, Minn., has been resumed after a lapse of eight years. Four barges, owned by the River Transit Company, of St. Paul, are to be used exclusively for freight carrying.

United Steamship Company.—According to a report from the Department of Commerce, Washington, D. C., the United Steamship Company announces that it has decided to open a new regular line between Montreal and Copenhagen for the transportation of grain and piece-goods to Danish, Scandinavian and Baltic ports.

Strachan Steamship Company.—Announcement has been made by the traffic bureau and the foreign and coastwise committee through the Jacksonville Chamber of Commerce that the city of Jacksonville will have a direct steamship line to Pacific coast ports, and the first vessel will begin loading cargo at Puget Sound ports for this city this month. The Strachan Steamship Company with the Moore & McCormack Company, steamship agents and operators, have made the arrangements and will operate five vessels in the service between the northwest and this port.

Detroit and Cleveland Navigation Company.—The establishment of a passenger route between Detroit and Chicago early next summer, with stops at Mackinac Island, has been announced by A. A. Schantz, president and general manager of the

D. & C. Navigation Company. The new route has been made possible by the building of two new steamships by the D. & C. Company, said to be the largest operating on any inland waterways in the world. These boats will be in commission next summer and will be put in operation between Detroit and Buffalo and, according to Mr. Schantz, the two boats now in operation on the Cleveland line will be put on the new route to Chicago. The first of the two twin steamships has been launched and christened the *Greater Detroit*. The second ship will slide down the ways in about six weeks and will be named *Greater Buffalo*. Mr. Schantz said that these two new boats will allow the company to put the two large steamships, *Eastern States* and *Western States*, on the Chicago run. A schedule of 36 hours between Detroit and Chicago will be put in effect at once and a single stop will be made at Mackinac Island.

Holland-American Line.—The Holland-American Line has announced that its steamer *Rotterdam* will sail from New York on February 6 of next year on a Mediterranean luxury cruise. Passengers are already being booked and this trip promises to be unique and different in many ways from the usual tour cruise. The cruise will cover calls at Madeira, Spain, Algeria, Athens, Constantinople, Palestine, Egypt, Italy and the Riviera. Final arrangements are being completed by representatives of the company with hotels, railroads and others to receive the visitors. The cruise is limited to 500 guests, thus eliminating all crowding or confusion as the *Rotterdam* can accommodate 1,000 persons.

White Star and American Lines.—Announcement of a joint passenger and freight service to be operated between New York and Hamburg by the White Star Line and the American Line has been made at New York. The American Line has maintained a service for cabin and third class passengers and freight between New York and Hamburg since 1920. At present it is maintained by the *Manchuria*, *Mongolia*, *Minnekahda*, *Finland* and *Kroonland*, all American flag ships. Owing to the disadvantages under which they labored, three of these steamers, the *Finland*, *Kroonland* and *Manchuria*, are to be transferred to the Panama Pacific for operation between New York and California ports, beginning in October.

The White Star Line has been operating a service for cabin, third class and freight between New York and Bremen since the spring of 1923, with the *Pittsburgh* and the *Canopic*.

Under the new arrangement, the White Star Line will transfer its German business from Bremen to Hamburg, where it will share with the American Line its new terminal at the Ross Quay, one of the best in Europe. It will dispatch its ships on dates alternating with those of the American Line, thus making a combined American and English flag service.

The first White Star Line sailing from New York in the new joint service will be that of the *Canopic*, October 18. The *Pittsburgh* will follow on November 8. The American Line's first sailing under the new schedule will be the *Mongolia*, October 25, and the *Minnekahda*, November 1.

Request for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The American Marine Congress

IF the approaching Marine Congress can, as the result of its deliberations, line up the many and varied interests directly concerned in, or contributing to American sea-borne trade, if it can formulate a United States shipping policy which will solve present problems and establish a firm foundation upon which the American flag may be permanently established on the seas, it will have accomplished its purpose and will have rendered the country a service of unparalleled value.

To a far greater extent than has prevailed at any previous convention, this congress will represent the general business interests of the country, and its work will embody the results of serious consideration on the part of bankers, manufacturers, railroad executives, representatives of agricultural organizations, exporters and importers; in short, of representatives of every form of commercial activity having interest in the country's ocean trade.

While the sum total of those directly engaged in maritime pursuits is relatively small and, by itself, limited in the accomplishment of political or national ends, the coming congress will represent a very large proportion of the business activities of the entire country. Under the guidance of its chairman, Secretary of Commerce Hoover, its deliberations will assume a broadly national aspect, and their result should be a shipping policy back of which the united business of the country can stand.

Approximately one hundred organizations have signified

their intention of participating, the delegates comprising men nationally known in almost every important industry. Co-ordinated by Mr. Hoover's unexcelled genius for organization and administration, the results of the deliberations of this unusual body of men may well prove epoch making in the history of the American merchant marine.

The Shipping Board's Policy

THE statement of the chairman of the Shipping Board, published elsewhere in this issue, gives an outline of the problem confronting that body. It is our experience that the chairman, personally, is a clear and concise thinker. That he has a comprehensive idea of the end to be sought from the Government's viewpoint is unquestionably true; but with six associates, with six different minds on many phases of the problem, there is little hope for an immediate solution. Further, since the board is essentially political and the policy of the Government seems to be that of persisting in holding the reins instead of disposing of the vessels and routes in a businesslike way, there is no prospect of early relief from the financial burden and hindrance to shipping involved in any continuance of the Shipping Board and its appendix vermiformis, the Emergency Fleet Corporation.

There is nothing in the program of the Shipping Board as given in Mr. Farley's communication that could not be carried out by private owners; and there is no necessity for continuing a great mass of expensive machinery for further experimental purposes. However, since the gods have decreed otherwise, what is the alternative?

Mr. Farley has made it clear that the Shipping Board will continue to operate ships indefinitely. But how about getting rid of useless vessels which, so long as they are riding at anchor, are derelicts in the shipbuilding industry?

A considerable number of ships have been disposed of; but a far larger number remain on the board's hands. Many of the latter are competitive or could be made so by changes in their machinery; but after deducting all ships of actual or potential commercial value there still remains a depressingly large fleet for which, even when looking into the future, no conceivable use is apparent. Some definite disposal of the mass of useless tonnage, and that at once, would appear to be the first and obvious step in the solution of the Shipping Board's problems. It is something which will have to be done eventually, and there is no good reason for further delay.

Turning to the competitive vessels, it is the intent of the

Jones Act and is understood to be the purpose of the board, as at present constituted, to dispose of them at the earliest possible moment to private parties.

The valuation of the board's fleet, recently published, works out to a considerably smaller unit price than that at which the ships have heretofore been held, but so far as we are aware no change in sales policy has been made. It seems to us that the time is opportune for pricing the vessels individually and at such a figure that their purchase by private interests would be within the limits of good business judgment.

Local Strength of Steel Ships

THE enormous energy stored up in a moving vessel, as well as the ability of a well-constructed steel ship to endure the severest punishment and successfully localize its effects, are well illustrated by the photographs of the damaged steamers *Hoven* and *West Arrow* which are reproduced elsewhere in this issue. In each vessel, notwithstanding the severity of the blow received, the damage was mainly confined to its immediate vicinity. In the case of the *Hoven* the longitudinal framing of the hull undoubtedly contributed to a considerable extent to this result. One cannot but wonder how much more extensive the damage might have been, had it not been for the heavy longitudinals which received the impact very nearly on end.

The results speak well for the character of material and workmanship entering into the construction of both vessels and should go far to set at rest the doubts entertained in some quarters as to the quality of the steel of which the Shipping Board vessels were constructed.

A Real Opportunity

THE present Government shipping situation, discouraging as it appears to the private owner and operator, has one hopeful side and presents a condition which, if opportunity is given in a proper and businesslike manner, may be developed in such a way as to be of the utmost advantage to the American merchant marine.

As described in detail elsewhere in this issue, a considerable portion of the Shipping Board's fleet is available for conversion to Diesel drive. These ships are of good design, so far as their hulls are concerned, and are at present in a fair state of preservation. We believe, if the board were to put in practice the methods of advanced modern salesmanship, that the potential value of the converted Diesel ships would be shown in a most convincing way.

The opportunity is at hand for the development of an American fleet of motorships at a cost materially less than is possible in any other country. It will be little short of a national calamity if, as the result of present depressed trade conditions and the consequent hesitancy of capital to embark in marine undertakings, this opportunity is allowed to pass unheeded.

By all means the Construction Loan Fund, now held by the Shipping Board for building purposes only, should be made available for the conversion of tonnage to Diesel drive and such legislation as is necessary to this end should be

enacted at the coming session of Congress. With the difficulties of capitalization thus relieved, there appears no serious obstacle standing in the way of placing competitive American motorships on the high seas and, at the same time, by the consequent increase in production of Diesel engines, enabling the builders of this class of machinery to approach more nearly to manufacturing conditions and the resulting reduction of cost.

The main and most frequently expressed objection to Diesel machinery is its present high cost and by enabling the builders to reduce this as the result of increased business is a matter second only in importance to the "Dieselizing" of these otherwise unproductive vessels.

It seems to us that along this line there is more of promise to American shipping than by any other channel now open.

The English Cinch

OVERTURES have recently been received from the British market by American hull underwriters, suggesting cooperation in preventing a further reduction in rates and values on hulls. The communication has been received from the Institute of London Underwriters and contains a recital of the understanding reached by London Underwriters as embodied in the following resolution:

"That in future no reductions in rates shall be given and no reduction in values without proportionate additional premium. This resolution to apply to steamers of any flag and also to renewals of foreign reinsurance placed in this market but not T. L. O. insurances."

The irony of this appeal can scarcely escape anyone familiar with the hull situation. It will be recalled that immediately following the cessation of hostilities in the world war the British underwriters notified the American market of the abrogation of their agreement to respect advisory ratings on American bottoms as promulgated by the American Hull Association. The object of this peremptory action was unmistakable. The American market, during the war, had obtained a large share of the American hull business, and the British underwriters wished to be free to recover as much of the business as possible, and did not want any impediment to this end so that they might obtain the business at whatever rate or on whatever conditions necessary.

The British market, because of its scope and financial backing, was in a position to capture the business regardless of the cost. We all remember the facility with which they accomplished their object. Rates were cut to a point where American underwriters, never very keen for hull business, were willing to have the business pass out of their hands, realizing that they could not hope to compete with the methods of the British market.

For five years British underwriters have paid through their nose for their grasping methods and have at last reached the point where they feel that a halt must be called. They now seek to consolidate and make profitable their gains and have the effrontery to call upon foreign underwriters for cooperation in retaining the business which they took in such a ruthless manner. It is to be hoped that American and other foreign underwriters will know how to treat such an appeal.

American Trade Needs American Ships

History Proves the Necessity for, and Common Sense Demands the Use of, American Ships for Developing Our Foreign Trade

By E. C. Plummer

Commissioner, United States Shipping Board

IN discussing our country's "great embargo" ordered by Congress on December 22, 1807, the *Americana* (Vol. 10, Page 273), states: "The agricultural classes who controlled the administration did not believe in commerce and preferred abolishing it to spending anything for its protection."

The broader views, which have come through a century's education, cause us to stand astounded before the proposition that there ever could have been a time when a majority of our people, either by affirmative declarations or by equally effective acquiescence, preferred to abolish our foreign commerce rather than to incur any expense for its preservation; yet an equally incomprehensive attitude toward American ships for our foreign trade dominates United States policies today!

AMERICAN CITIZENS LACK NATIONAL VISION

The need of foreign trade for the United States is recognized by all. The necessity for foreign markets where our surplus goods may find an outlet is understood by many, but the fact that American ships are absolutely essential to the proper development of such markets appears to be understood by but a few, if we may judge popular comprehension by results actually attained. Until there has been legislation which actually puts into the foreign trade of this country ships owned and operated by citizens of the United States the people of this country, whatever their private views may be, must stand charged with the same lack of national and commercial vision as brought about the legislation of 1807-1809, and ended in war.

WHAT OUR COMPETITORS KNOW

Our competitors clearly perceive the mistake this country is making. Says *Fairplay*, England's marine journal, quoting Britain's commercial authority (September 20, 1923):

"One cannot but be struck with the comparatively small amount of United States foreign exports in comparison with the colossal production of that country. * * * The question which the United States will presently have to answer is to what extent her manufacturers can rely on home consumption for a market for their goods. * * * How long this somewhat artificial prosperity will last is quite another question. If there is no market for dumpable surpluses, they will not represent wealth; and in such case the effort will be as wasted as our own in 1920, when we produced more than we could sell here and abroad, with staggering consequences."

The vast unemployment, on account of which England has spent millions upon millions, is one of the "staggering consequences" referred to here—and the end is not yet!

The exhaustion of all our surplus supplies brought about by the world war and the great deficiency in building operations which we are now engaged in supplying have created a home market which has placed American labor in a very advantageous position; and it is the part of wisdom for us to take such action now as will enable us to keep that labor fully employed when our exceptional industrial activities shall have become normal, as they necessarily will become within the next five years.

OPERATION OF AMERICAN SHIPS PAYS \$100,000 PER DAY TO AMERICAN LABOR

Here the importance of a foreign trade merchant marine as a United States industry in itself should be considered. The wages paid on Shipping Board vessels in that trade alone is eighteen million dollars a year. The voyage repairs on those ships alone amount to twelve million dollars per year. These two items alone, to say nothing of supplies and equipment replacements, mean one hundred thousand dollars per day in wages paid to American labor. And ships in their

construction and upkeep call upon practically every industry for a contribution—everything that goes into the building of a home or a hotel is to be found in a modern steamship. This is only the constant, day-by-day employment resulting from ship operation. It does not include the vast employment created by ship building.

Now we come to the persistently iterated fallacy that there are always foreign ships enough to handle properly all the foreign trade of the United States.

FOREIGN SHIPS WILL NOT PROVIDE PROPER TRANSPORTATION FOR OUR GOODS

That, as a rule, there are ships enough under foreign flags to furnish transportation for American goods may be admitted; but that they have furnished, or will furnish, proper transportation facilities for our goods is not true. Take this admission made in *Fairplay* on August 30, last, discussing the movement of only one of America's great staples, cotton. It says:

"The Americans often found that there were no boats available
(Continued on page 652)"

E. C. Plummer

American Ships Are Carrying Less Than 25 Percent of the Overseas Commerce of the United States

Figures Supplied by the Research Department of the Shipping Board Show That the Majority of Our Exports and Imports Is Handled by Foreign Shipping

THE merchant marine of the United States may properly be divided into four distinct classes according to the services in which employed.

(1) The ocean going vessels of one thousand gross tons and over employed in the foreign trade of the United States.

(2) Vessels of 500 gross tons and over employed in the coastwise and intercoastal trade, in offshore traffic.

(3) Vessels employed on the Great Lakes exclusively.

(4) Vessels employed on inland rivers, land locked lakes, inland bays, and inshore traffic.

Of the four classes the first is the one to which we look to establish and maintain our position as a maritime nation in times of peace and to provide us with adequate transportation in time of national peril. The foreign going ship is the one that must meet the competition of other nations for the carrying trade of the world and, in a survey of the activities

American Trade Needs American Ships

(Continued from page 651)

for them in the summer months. The Shipping Board has supplied that deficiency. * * * the want of regular sailings had been in existence for many years, but the European carriers had made little effort to supply it."

There's an admission by the spokesman of our chief competitor in world trade! This attitude has been typical; and it is one of the principal reasons why there has existed that "comparatively small amount of United States exports," cited by the British commercial authority above referred to.

FOREIGN DISCRIMINATION AGAINST AMERICAN TRADE

But there has been something more than mere neglect. A few years ago Senator Fletcher, of Florida, exposed in the United States Senate the discriminations which, by increasing the freight charges on American cement sold to South American purchasers, made it impossible for that United States product to compete with the far more cheaply transported British product; and that case where the sale of fifty American-built locomotives to Argentine purchasers was defeated by an increase of three dollars per ton in the ocean freight rate on them will readily be recalled.

The recent exposure by our Postmaster General of the systematic detention of mails to the United States that they might go on British ships, ignoring available American tonnage, speaks for itself.

I am offering no criticism of such practices as those referred to here—on the contrary, I admire the wisdom of Britons who realize the necessity of their giving every possible bit of business to their ships and to their manufacturers. I cite these facts merely as showing how foolish is the claim that foreign ships can or will serve the people of the United States as well as ships belonging to and operated by our own people. Now for a concrete case showing how American ships build up the foreign trade of this country.

HOW AMERICAN SHIPS BUILD UP OUR FOREIGN TRADE

When the United States had recovered its commercial equilibrium following the civil war era, the United States and Brazil Steamship Company was established. As soon as it had shown material results in building up American business with the east coast of that continent sharp competition was established by Europeans, and in 1890 the line was driven out of business. Then, as now, the extra cost of operating ships under the American flag was a fatal burden which Congress had imposed but refused to share. The net result was that Europeans became predominant in foreign trade

then so that at the beginning of the world war Great Britain had engaged in trade with the east coast of South America alone more tonnage than she had with the east coast of the United States, Canada and all the West Indies combined (Page 141, Report to Parliament, 1918).

Following the world war United States vessels established a regular and high-class service to the principal ports of Brazil and Argentina, with a result which may well be stated in the words of Sir John E. Thornycroft, whose recent report—appearing in *Lloyd's*—says:

"The Americans are pushing everywhere and taking control. Large orders for locomotives, for coal plants, grabs, etc., have recently gone to the United States, and a new steel factory is equipped with American machinery, while it is probable that large orders for electrifying the State Railways will also go to America."

COMMERCE WITH THE FAR EAST INCREASED BY AMERICAN SHIPS

Take Oriental ports to which the Shipping Board now operates two first-class lines of steamers, the Admiral and the Pacific Mail. In 1914 our total commerce with the East amounted to but 2,418,654 tons, of which less than 10 percent was carried by American vessels. That trade has increased to 5,255,000 long tons, of which 55 percent is carried in American vessels.

Unquestionably American ships are essential to the proper development of our foreign trade; unquestionably the heavy losses which Shipping Board vessels have suffered during this continuing period of depression in ocean freight rates have been much more than made up to our people in savings on transportation charges paid by our exports and imports (grain having been carried this year at as low as six cents per hundred weight), as well as in the development of foreign markets for our products; and since the cost of operating American ships is from seven to ten percent higher than the costs of their competitors, as a result of American standards, unquestionably the Government should put our ships on an equality with their competitors, just as it does in the case of other great industries, so that the Shipping Board ships may be sold and private enterprise given an opportunity to develop the foreign trade of this country, which trade within five years will prove to be one of the very essential pillars of this country's prosperity.

CORRECTION.—On page 618 of our October issue the captions of Figs. 7 and 8 in the paper on Scotch boiler tests were inadvertently interchanged; i.e., the higher efficiency curve applies to the forced draft test and the lower efficiencies to the induced draft.

of American merchant vessels and their employment, is the only class in which comparisons can be made that would indicate the growth or recession of our position as a factor in transporting the manufactures and products of our own country, the raw materials necessary to our industries, as well as the manufactures of other nations.

GROWTH OF MERCHANT FLEET

The past decade has witnessed the growth of our steam merchant fleet (exclusive of Lake vessels) from 725,000 gross tons on June 30, 1914, to 11,600,000 gross tons on July 1, 1923. Practically the whole of this increase is due to the construction program of the United States Shipping Board. The total gross tonnage of our vessels is not a conclusive measure of their usefulness, however, as many of the vessels registered for foreign overseas trade are laid up and in the instance of the wood vessels condemned for salvage although still remaining in the documented lists. The measure of our activities in foreign trade lies in the consideration of those

employed in the trade with the nearby foreign regions 39 passenger vessels of 168,417 gross tons, 78 cargo vessels of 220,118 gross tons and 72 tankers of 369,893 gross tons—a total of 189 vessels of 758,428 gross tons. These vessels carried in June of this year 557,000 long tons of dry cargoes or 46 percent of the total regional commerce with the United States and 952,000 tons of oil or 77 percent of the total imported. The combined traffic with the nearby regions amounted to 2,446,000 long tons of which American vessels carried 1,509,000 tons or 61.7 percent.

VESSELS IN OVERSEAS SERVICE

In the long haul traffic of overseas trade the employment of American vessels and the proportionate cargo carried is best illustrated by subdividing the trade into continental regions and the following tables illustrate the tonnage engaged at the close of the fiscal year and its distribution and the amount of the regional proportion of commerce carried by American vessels.

Overseas Employment of American Steam Vessels of 1,000 Gross Tons and Over On June 30, 1923

vessels of 1,000 gross tons and upward in continuous service on regularly established routes, that are the carrying factors of our ocean transportation system.

DIVISION OF FOREIGN TRADE

The foreign trade of the United States falls naturally into two divisions—first, trade with foreign ports of North America, Central America, Mexico, West Indies, and other foreign islands of North America to which voyages are relatively short and the tonnage requirements in relation to the volume of cargo carried are considerably less since the turnaround is more frequent, and, second, the overseas voyages to Europe, Africa, Asia, Australia, the islands of the Pacific and South America where the annual turnaround is greatly reduced and the tonnage requirements in proportion to the cargoes carried are much greater.

At the end of the fiscal year, June 30, 1923, there were

The vessels of the United States Shipping Board predominate in the overseas trade, the ratio being about 5 tons of Government owned vessels to 1 ton privately owned, this ratio of course varies in the different regions. Where the maintenance of services would be unprofitable for private capital, and markets and transportation by American vessels must be established and maintained, the Shipping Board vessels have been kept in continuous service despite the fact that they have operated without profit, as for instance in the transatlantic European services, where the keenest competition is met from maritime nations whose operating costs enable them to carry cargoes at the lowest ebb of freight rates, either at a small margin of profit or with an even break, the privately owned tonnage of the United States is represented by 52,879 gross tons while the Shipping Board maintains in this service a total tonnage of 1,075,687 gross tons of cargo vessels.

American Passenger Ships

TO an American, the crossing of the Atlantic for the first time on a vessel flying his country's flag is an event fraught with significance and one calculated to stimulate a train of thought not otherwise awakened.

Particularly is this true with one whose whole business life has been spent in close touch with the shipbuilding industry and to whom the Stars and Stripes at the peak of a fine transatlantic liner represents the fulfilment, at least in part, of a life-long hope.

NORTH ATLANTIC THE PREMIER STEAMSHIP ROUTE OF THE WORLD

Of all great ocean routes, that between Europe and North America is the most important; and it is here that commercial naval architecture and marine engineering have attained their highest development—in size of ships, speed, luxurious accommodation and safety. The blue ribbon of the North Atlantic is the blue ribbon of the maritime world.

In the sailing-ship era, American vessels, both as regards size and speed, held the Atlantic records for many years; but it is no part of the writer's intention to present a history of the decline of our merchant marine in overseas trade. The fact that the low point has been passed and that America is now in a fair way to regain at least in part her former enviable position on the North Atlantic makes more cheerful reading and the story of what has already been accomplished, however imperfectly it may be told, is of vital interest to all Americans who have at heart the welfare of their merchant marine.

UNITED STATES LINES A NATIONAL INSTITUTION

As is well known, the Shipping Board, through the United States Lines, has for the past two years been operating vessels in the North Atlantic passenger trade. It would appear, however, that the character and the extent of the service rendered by these lines of steamers are not as

well nor as generally recognized as they deserve to be, although the popularity of the service has increased by leaps and bounds during the past summer. The reports of passengers who have made passages by these vessels, and the writer has talked or been in communication with many of them, are practically unanimous as to the high quality of the service rendered and, in the minds of a steadily growing number of Americans, the line is established as a national institution.

As at present conducted, the United States Lines are operating the following vessels:

*S.S. George Washington
Arriving in Port*

"Hitting it Hard"

"The North Atlantic Range"

Setting a High Standard

James Swan

Leviathan, New York-Cherbourg-Southampton; *George Washington*, *America*, *President Roosevelt*, *President Harding*, *President Arthur* and *President Fillmore*, New York-Plymouth-Cherbourg-Bremen-Southampton; and four smaller vessels, *President Polk*, *President Monroe*, *President Adams* and *President Van Buren*, between New York, Plymouth and London, two of them calling also at Queens-town.

The *Leviathan* is too well known and has been too often described to need any further comment at the present time. She is one of the world's finest ships, and after a period of special management, has just been taken over by the United States Lines, and will undoubtedly be run by them in the efficient manner which has built up the popularity of their other vessels.

THE GEORGE WASHINGTON POPULAR WITH TRAVELERS

In the *George Washington*, the line possesses, thanks largely to its own efforts, what is perhaps the most popular vessel with American travelers in the Atlantic service today. This fine ship is an intermediate type steamer of 23,788 gross tons, approximately 20,000 horsepower and over 17 knots' speed in average weather. For solid comfort it is hard to imagine anything more nearly perfect than this ship. The decks and cabins are spacious, the public rooms well arranged, comfortably furnished and well finished and decorated, but without the excessive decorative and lavish and really unnecessary detail which to many appears out of place on shipboard. Furthermore, the vibration and discomfort often experienced in heavy weather on very high powered ships are practically absent.

The writer has recently had the good fortune to make a round trip on the *George Washington*, the trip east unusually smooth and the return in heavy weather. The behavior of the ship in the heavy head sea was perfect and clearly showed the superior comfort of the intermediate type ship under rather trying conditions. So far as management and the internal running of the ship were concerned, there was nothing but praise from everyone—for the veteran captain and for all of his efficient and smooth running organization; and it is pleasing to know that this state of mind is also reflected by those who have traveled on the other vessels of the line, several fellow passengers telling the writer that they had experienced equally pleasant and satisfactory service on the *America*, the *President Roosevelt* and on the London ships.

The *America* is also an intermediate ship, somewhat smaller than the *George Washington*, but in general of similar design and type.

Capt Cunningham on the Bridge with Gen. Pershing

How a 75 Mile Gale Looks

"A Heavy Head Sea"

Looking Out of an Air Port

The *President Roosevelt* and *President Harding* are of the "535-foot" type, the construction of which was commenced during the war, as transports, but altered later to combination passenger and cargo vessels. While not as large as the *George Washington* and *America*, they are somewhat more speedy, have fine accommodations and are good sea boats.

The *President Arthur* and *President Fillmore* are old German vessels, and here again the placing of them in service was due to the lack of other more suitable vessels.

The four *Presidents* running to London are in reality cargo vessels, having limited passenger accommodations. While the quarters on these ships are excellent and the service rendered appears to have called forth nothing but praise, they are not suited to the trade and were only placed on this run as a measure of expediency. They have now been sold and it is understood are to be replaced by ships of the Hog Island transport type carrying cargo only. So far as passenger service is concerned the demand warrants the placing on this line of large intermediate type ships, were any such available.

UNITED STATES LINE LACKS HOMOGENEITY

From this brief description, it at once becomes apparent that the fleet of the United States Lines is almost entirely lacking in the important element of homogeneity and the difficulty of maintaining an evenly balanced service thus greatly magnified. The salient feature is that, notwithstanding the lack of proper tools to work with, the management has succeeded in building up a business good-will of the greatest value and one which should be maintained at all costs, if America is to retain a place of any importance in the Atlantic passenger trade.

By far the larger part of the income of all vessels engaged in this service comes out of the pockets of American citizens. There is now offered an opportunity for the latter to obtain excellent service on their own vessels; and that this opportunity is being taken advantage of is shown by the heavy passenger lists of the American ships as compared with those of foreign lines.

What then are the probabilities of holding and building up this business in the immediate future? The *Leviathan* by herself cannot maintain first class high speed service. At least two other fast vessels are needed by next summer if a well-balanced express service is to be established, and more large ships are needed if German competition is to be successfully met next year. The line to London does not appear of quite the same importance as the others; but there seems little doubt of its success if proper vessels can be provided.

NEW AMERICAN LINERS NEEDED

Undoubtedly, the ultimate end to be sought is the construction of new American vessels for all of these services. With operating conditions as at present, it seems out of the question for private companies to undertake the construction of Atlantic liners and, even if Congress should decide to pursue this course, it would be a matter of at least two years before the new vessels could be placed in commission. It remains then to make use of such ships as are at present available if the business is to be held in the immediate future. The *Republic*, now being reconditioned at Newport News, is a fine ship but lacking in the important element of speed.

AGAMEMNON AND MOUNT VERNON SHOULD BE RECONDITIONED

It seems of utmost importance immediately to build up the high speed service. Apparently the only way to accomplish this in time for next year's business is to recondition the *Mount Vernon* and *Agamemnon*. These two fine vessels have unexcelled records in the Atlantic passenger service, and their potential value cannot be neglected. Their hulls and propelling machinery are in fair condition, and it is believed that passenger accommodations, similar in character to those on the *George Washington*, could be constructed at a relatively moderate cost.

Of course the advisability of reconditioning depends upon its cost. If it were absolutely necessary to carry out the rather radical changes which have been proposed and which would involve an expenditure of approximately \$8,000,000 on each vessel, the universal opinion is that the ships are too old to warrant any such outlay. On the other hand, if they can be put in commission at a cost of not over \$3,500,000 each, and it is believed that this is quite possible, the growing business and national importance of the line would appear to amply justify this course.

Whatever decision is finally arrived at regarding the use of these vessels, they should not be disposed of to foreigners. If they are sold to foreign account, their appearance by next year as our competitors for Atlantic passenger trade is practically certain.

America has already established a service second to none in efficiency and popularity, limited only by the number and type of the ships in operation. The means are at hand for increasing and perfecting this service, and we believe it to be the will of a steadily growing body of her citizens that this should be done and that America should retain her place in the transatlantic passenger trade.

Steamship *George Washington* of the United States Line

The Navy and Merchant Marine Are Interdependent

Both Must Be Maintained for the Safety and Prosperity of the Country—Large, Fast Passenger Vessels Our Greatest Need

By Edwin Denby

Secretary of the United States Navy

IF we are to maintain the American standard of living as it exists in our country today, we must have foreign trade. If we are not to pay toll to foreign shipping and have our foreign trade at the mercy of competitors, we must have a fair share of our foreign trade carried by our own merchant marine. If we are to be a great power, truly independent and free from commercial subserviency, we need a great merchant marine to carry on our commerce.

All great maritime nations have made provisions, in some way, for taking merchant shipping into the naval service in time of war. This has taken the form of subsidies or subventions, direct or indirect, discriminating rates to further the growth of the merchant marine, etc. At least the merchant ships can be listed and classified and plans made for their transfer to the Navy.

When war comes and the entire military strength of the nation is to be exerted, the Navy must draw vessels from the merchant marine for navy use—cruisers, transports, fuel ships, repair ships, distilling ships, hospital ships, mine layers, mine sweepers, patrol ships, destroyer tenders, submarine tenders, aircraft tenders, tugs and supply ships of all kinds. In addition, the merchant marine must continue the transportation of articles of commerce essential to the welfare of the people as a whole. When we organize for war, the Navy and the merchant marine become practically one service administratively. During the world war, 95 percent of our merchant shipping was under Government control, particularly as to cargoes and routes.

In 1898 we armed the few large passenger liners we had for distant scouting and general cruiser service. They did what they could, but due to the lack of numbers Cervera's fleet cruised at liberty in the West Indies, and was discovered only after it had been in Santiago for some time. This with a war at our very doorstep and against a power that was even

© Harris & Ewing

worse off than we were.

In the employment of converted merchant ships as cruisers, many conditions may arise. Our Navy may be employed in protecting trade routes used by our merchant marine; it may be engaged in raiding the sea lanes used by the enemy or denying him the use of them. Its operations may or may not lead to fleet actions. Our merchant marine may be carrying on foreign trade or it may be shut up in port. In any case, the Navy will be short of regular cruisers and the converted merchantmen must fill the deficiency. As the regular Navy is reduced the importance of the converted merchantmen increases. A large merchantman, converted to a fighting ship, may carry a battery formidable for a cruiser and have a great fuel endurance, and, if there are no regular cruisers available for operations in a particular theatre, the converted merchantman becomes of prime importance there. Our greatest need would be for large fast

passenger vessels for use as transports, scouts, armed cruisers and seaplane carriers. In this class the United States is very deficient, having only four such vessels of over 20 knots.

As an addition to naval strength, the personnel of the merchant marine—a body of men with the sea habit—is a naval asset, whether in war it be employed on regular naval vessels, on merchant vessels converted to naval use, or on merchant shipping for naval or merchant service. When we entered the world war, our battle fleet had to devote itself to the training of raw recruits in the most elementary duties of the seamen, because we had no merchant reserve to call upon.

The Navy can never be considered adequate to fulfill its mission until it has the backing of a good merchant marine, but a good merchant marine is a poor investment without the protection of a good Navy. In peace and in war the two are interdependent. In my opinion the safety and prosperity of the country demand that we maintain both.

A Merchant Marine Is Necessary for National Defense*

The Navy, Our First Line of Defense, Especially Needs the Support of a Strong Fleet of Merchant Ships

By Rear Admiral Charles P. Plunkett, U. S. N.**

EARLY in the history of our country the question came up of providing for a purely American merchant marine. That question has been agitated every year since then. It has taken every conceivable form that you could think of and the whole reason for all these variations, knowing what they want to accomplish, is the fact that we have been up against opposition, the opposition of the older nations of the world, and that opposition today is just as strong as it ever was.

I remember very clearly being present on the floor of the House of Representatives as a spectator when President Wilson read his war message to Congress and I couldn't help but think as the words fell from his lips that all this trouble came from one thing and that was the fact that we were not sufficiently strong on the sea to prevent any nation questioning our rights there.

We don't want to control the seas of the world. All we want is equality—equality in quantity, equality in justice, equality in opportunity.

I was present last year, when our late, lamented President read his message to Congress on the merchant marine. It is amazing that Congress could have adjourned without giving affirmative action after hearing what that great man said and the facts which he produced which were absolutely indisputable. But they did. The House passed the bill but it fell by the wayside at the other end of the Capitol and we are today in the same position that we have been in for over one hundred and thirty years.

Don't think for one minute that because you built a few ships during the war and you have a Shipping Board, a government organization for ascertaining information and for operation of those ships, you have a merchant marine. I don't know why I should make that comment, because every one of you knows that the thing that carried through this war was the people and not the material.

Now, there is our situation. We can go on building ships until the end of time, but if we don't create the people to operate them and run them and create all of the facilities connected with the operation of them, to the far ends of the earth, we will never accomplish what we are after.

POSITION OF AMERICAN SHIPS IN FOREIGN TRADE

Today our exports in American bottoms are about 38 per-

* From a speech made at the national convention of the New York State Department of the American Legion, Saratoga Springs, New York, September 13, 1923.

** Commandant of the Third Naval District, New York Navy Yard, Brooklyn, N. Y.

cent of what is shipped out of the country. Our imports are about 32 percent in American bottoms. The Congress has declared that it is the policy of the American people that it shall be at least 50 percent. What is the good of declaring a policy if it is not carried out? Our trouble is that we are forever declaring policies but only going into them halfheartedly. We have all these various policies and here and there are men working with their coats off to carry them out but we don't get the support for it that we ought to have.

We have leaders. We have intelligence. We have money—everything that is needed to put this merchant marine on the high seas and operate it, so that the farmers who are crying now about the price of wheat will not be bothered about their market. They are only one of the many who need this merchant marine. There is absolutely no reason in the world why we should not have it.

THE MERCHANT MARINE AND NATIONAL DEFENSE

Now, we talk about national defense. Why, the strongest argument that President Harding brought out for the merchant marine was the fact that it was an essential part of any scheme for national defense, that we could not be fully prepared unless we had a merchant marine. I can assure you that it is a pipe dream to take the naval fleets of America

seven thousand miles across the Pacific without an American merchant marine.

In order to do anything in this country of ours it has to take the form of a movement. It must be labeled and spread on the headlines of the press. That isn't 100 percent Americanism. The people are just not thinking 100 percent American. Your country expects that when you have spare moments, you will think about America and what is going to make America first, not something else, but first. And we can't be first unless we have a merchant marine.

FORMER POSITION OF GERMANY ON THE SEAS

Now, if you will take the time to read Admiral Mahan's splendid book on the "Influence of Sea Power on History"—every word of which is founded on fact—you will see why it is that things are as they are all over the world and how impossible it is to say to all the different tribes that existed in the past and exist today that each and every one of them shall be a separate and independent nation determined by themselves. Germany had no navy to speak of until the Kaiser read that book of Admiral Mahan's. Say what you please about the man, he realized that Germany could never

Shipping Board to Readjust Methods of Handling Its Fleet; Existing Routes to Be Consolidated

Essential Lines Will Be Gradually Extended and Transferred to Private Owners as Soon as Purchasers Can Be Found—Regular Sailings at Fair Rates To Be Maintained

By Edward P. Farley
Chairman, United States Shipping Board

THE Shipping Board's immediate problem is the operation of essential trade routes with the least possible drain on the national treasury. These trade routes should be gradually built up by efficient service and by extending our freight connections and creating a good will which will result in shippers sending their goods over our lines.

With the depressing effect of European conditions on world shipping, it must be expected that there will be but small profit in the operation of the most economical tonnage. Our own tonnage, necessarily more expensive, must be expected to show a loss in operation. During the period in which these losses are to be anticipated, the greatest possibility of economies lie in the consolidation of routes so as to carry the cargo offered with the fewest possible ships. This is the immediate aim of the Shipping Board in the consolidations being worked out, and in making them the board is creating that flexibility of movement which is essential to successful operation of shipping.

With the consolidation of routes, we will eliminate the ships now operating in excess of the number needed to carry the tonnage offered, while maintaining reasonable regularity of sailings. We will then have arrived at what may be considered bed rock conditions from which a gradual enlargement of the fleet can be anticipated as confidence grows in the services established and as international trade conditions improve. It is the intention of the Shipping Board, so long as it is operating any of the essential

© Harris & Ewing.

Edward P. Farley

trade routes, to put on whatever additional tonnage the business conditions warrant and to maintain on the routes fair and reasonable rates.

In connection with rates it should be borne in mind that it is of no permanent advantage to shippers, to develop or permit a condition to exist where their goods are carried at less than cost, including a fair return on invested capital. If any business is being conducted at a loss, it is but a question of time before a readjustment must be made in which, through the elimination of competition, new and higher prices are set up to the disadvantage of those dependent on that business.

We can perhaps say, therefore, that our immediate problem is the readjustment of the methods of handling the fleet, so that the business obtainable on essential trade routes can be carried with the smallest possible loss. Then we must turn to the gradual building up and extension of these lines through the service afforded, and provide for their transfer to private hands as soon as purchasers can be found. These purchasers will appear when, through im-

proved operations or changed shipping conditions, there is a possibility of profit in operation, and not before this time.

There is a differential against the American ship operator as compared with operators under foreign flags. There may be a difference of opinion as to the amount of this but it is a matter of national importance and we can confidently rely on Congress to enact specific legislation when its character and extent are clearly made known.

take her position among the nations of the world until she had a navy and a merchant marine.

With all due respect to everything else that has been said on this subject, we can thank God that the war came in 1914 and not in 1921 when the German fleet would have been completed.

Here we are today, the inventors of aviation, the inventors of the submarine, and where are we? We are way down at the bottom. We start things but we don't get anywhere. The only thing in my recollection that we have put over in first

class style was the world war and we had to do that or we would have been wiped off the face of the earth. That is the only thing that put our strength behind that war, the fact that we knew what we were up against and were determined to fight it out.

We have always talked defense. But you can't be strong defensively, you can't keep up the morale, unless you instill into the people who are carrying on, the idea that some day they may have to fight. It is ridiculous to try and support anything of the kind on any other basis.

Plan Proposed by the United States Ship Operators' Association for Operation of Government Tonnage

AT the joint hearing held in Washington by the United States Shipping Board on August 28, 1923, a plan for the operation of Government vessels was submitted by the United States Ship Operators' Association.

The following abstract gives an idea of the general intent and scope of this proposal:

The purpose of the plan is to put on the operator or agent a greater measure of responsibility than at present, so that, if the present losses increase, the agent will bear a substantial share of such increase; whereas, if they diminish, he will receive some of the resulting benefit. With these ends in view, the plan provides for the fixing in each service of a standard voyage figure based on operations for a number of months to be agreed upon. If the agent does not do better than the standard figure, he will get no compensation for operating and will receive only a husbanding fee. If the agent falls below the standard voyage figure, he will be obliged to bear an agreed upon percentage of such deficit. If his operation shows a surplus above the standard figure, he will receive a percentage of such surplus and the remainder will go to the Shipping Board, but of this remainder a certain part is to be put into a purchase and building fund

CONSOLIDATION OF ROUTES

The association agrees in principle to a consolidation of trade routes for the purpose of limiting competition between vessels of common ownership, but suggests further discussion along this line.

Each agent, when undertaking operation, must have tangible net assets of an amount to be later determined for each vessel that he undertakes to operate.

Vessels shall be allocated by the Shipping Board to agents to be operated by them as the board's agents on different trade routes, the agents guaranteeing maintenance of these routes for a definite period.

Vessels shall be delivered to the agent in good condition, fully equipped to 100 A-1 class and shall be so maintained; ordinary repairs and replacements chargeable to voyage account; expenses of reclassification, of maintaining class and of major repairs, also any losses arising from inherent defects and replacement of gears and pinions in turbine vessels to be for the board's account.

Premiums and assessments for P. and T. insurance shall be charged to voyage account, but at rates not higher than the market. Insurance against fire and marine risks, including collision liability, shall be maintained by the board for its account, fully covering all concerned. In case of insured losses, the board shall make any advance of funds necessary pending collection of insurance. Liabilities for collision, personal injury, cargo damage, and other liabilities of an accidental nature are to be assumed by the board.

All expenses arising from a loss of time in excess of 24 hours and due to accident to vessel or cargo shall be borne by the board.

An audit shall be made covering an agreed period on each trade route for the purpose of fixing for that route the net result per voyage for such period. This audit shall take account of all revenue and disbursements arising from operation, but shall not include ship insurance, depreciation or interest.

DIVISION OF PROFITS AND LOSSES

The agent shall collect all earnings and pay all operating expenses, except as otherwise stated in this instrument. At the conclusion of each voyage, he shall render an account to

the board, showing the results as compared with the standard figure. The surplus or deficit thus determined shall be divided between the board and the agent. The agent shall receive no compensations for operating other than that above provided for.

PURCHASE AND BUILDING FUND

A certain percentage of any surplus paid to the board under the provisions of the preceding paragraph shall be deposited in a bank or trust company in the joint names of the board and the agent as a "Special Purchase and Building Account." At any time during the life of this agreement, this fund may, at the election of the agent, be devoted to any or all of the following purposes:

- (a) Making good the operator's losses on voyages during the term of the agreement.
- (b) Converting any vessels covered by this agreement into Diesel engine vessels.
- (c) Purchase of tonnage from the board.
- (d) Building new American tonnage for the agent's account.

If the agent does not use this fund for any of the purposes set forth, during the term of the agreement, his rights therein shall cease, except that he may apply it to build new American tonnage contracted for within a stated time after the termination or cancellation of the agreement.

HUSBANDING FEE

The board shall pay to the agent an agreed sum per vessel per month which shall be debited against the voyage account.

All agent's disbursements charged to the voyage account shall be net, and he shall derive no direct or indirect profit therefrom. Where the agent provides terminal facilities, rates and terms for their use shall be agreed upon between the agent and the board.

The agent shall have control of operations, including decisions as to rates of freight, conferences, sailing dates and personnel. He shall also supervise all ordinary repairs and replacements. He is to have the benefit of all information possessed by the board relative to the vessels and trade routes in question.

The board will not allow interference or competition on the routes covered by the agreement by any other Shipping Board tonnage nor by any vessels purchased from the board at less than full world market rates.

The board agrees to substitute for vessels which may be a total constructive loss or which have to undergo major repairs, other vessels of similar size, type and condition.

In order to provide for proper maintenance of service, and seasonal movement of cargo, the number of vessels in each trade shall be increased or decreased as traffic requires, the board agreeing, at the agent's request, to supply additional vessels or lay-up surplus ones. Vessels while so laid up shall be for the board's account and risk.

If the agent shall have been found by a board of arbitration guilty of wilful violation of this agreement, or of inefficient management, the board may cancel the agreement on 30 days' notice. The agent may cancel the agreement on 30 days' notice, if he has sustained operating losses exceeding the sum in the "Special Purchase and Building Fund" by an agreed amount per vessel operated.

The above abstracts cover the main points of the operators' plan and proposed operating agreement. Some modifications were submitted to the Shipping Board on September 13, 1923, but the proposal remains substantially as here outlined.

Shipping Legislation That We Have and That We Need

Laws Now on Our Statute Books That Would Greatly Benefit American Shipping, If Enforced—New Legislation Needed

By "Old Scotch"

BEFORE embarking on a new campaign for the American merchant marine, or for any other enterprise, it is always well to take stock of our assets as well as our needs to accomplish the end for which we seek.

The forthcoming American Marine Congress is called largely to discuss our needs for the future in maintaining a sufficient number of American ships in our foreign trade. The passage of the Jones Bill, otherwise, known as the Merchant Marine Act, 1920, was supposed to provide all necessary legislation for the time being. Circumstances, however, have made that Act, comprehensive as it then was, entirely inadequate to accomplish the policy laid down in its preamble "To do whatever may be necessary to develop and encourage the maintenance of such a merchant marine," that is a fleet of the "best equipped and most suitable types of vessels sufficient to carry the greater portion of our commerce, and serve as a naval or military auxiliary in time of war or national emergency."

This act, approved June 5, 1920, contained much that is valuable for the accomplishment of such a policy, some of which has reached fruition and some of which has progressed no further than the statute book. The principal sections among the latter are as follows:

SECTION 5. SALE OF VESSELS

"The Board is authorized and directed to sell, as soon as practicable, consistent with good business methods—all of the vessels—acquired by the Board."

This has been complied with in part, and in justice to the Shipping Board it would seem that they have acted in accordance "with good business methods," when we consider the almost universal collapse of the demands for ship tonnage, due to the terrible falling off in ocean transportation. Sales of a small amount of tonnage of desirable vessels have been made at prices approximately the prevailing world's tonnage values, which have been compatible with the almost negligible demands. No further legislation is needed along these lines, as it is presumed that the Board will take advantage of their authority as conditions change for the better, which at this time seems to be the only way they can change.

SECTION 11. CONSTRUCTION LOAN FUND

"The Board may annually set aside out of the revenues from sales and operations a sum not exceeding \$25,000,000 to be known as its construction loan fund, to be used in aid of the construction of vessels of the best and most efficient type for the establishment and maintenance of service on steamship lines deemed desirable and necessary by the Board—. No aid shall be for a greater sum than two-thirds of the cost of the vessel or vessels to be constructed, etc."

The setting aside of funds received from operations is more or less of a mirthsome provision, in the light of events subsequent to the passage of the Act, but there have been very substantial receipts from "sales" of ships and property. Singularly enough, so far as is generally known, this provision for aiding "steamship lines" has been resorted to in but one instance, and that was for the New York-Duluth service. The Board's legal talent, in approving this loan, was much more progressive than Steamboat Inspection interpretations that laws for "steamships" are not applicable to motor-driven vessels. However, there can be no question but that this sec-

tion of the Jones Act will be very helpful when the time comes for American shipowners to make investments in needed equipment as water-borne commerce picks up.

It should be noted that this loan fund is not alone applicable to new vessels in the foreign trade, as is evidenced from the fact that the only loan known to be made thus far has been to a line employed in domestic trade. As this legislation is very much akin to the farm-loan provisions of law, and as it can be used much to the advantage of our agricultural interests, as for example the loan made on the motorships which will carry large quantities of grain, butter and eggs from the Northwest to the Atlantic seaports at lower than rail rates, it should and probably will be kept on the statute books.

SECTION 21. EXTENSION OF COASTWISE LAWS TO INSULAR POSSESSIONS

"That from and after February 1, 1922, the coastwise laws of the United States shall extend to the island territories and possessions of the United States not now covered thereby—"

This is one of the most valuable of the unenforced provisions of the Jones Act, as the question of the extension of the coastwise laws to the Philippines is herein authorized. However there were certain provisos attached to the section, the principal of which provided that it would not be effective so far as the Philippines are concerned until the President issues a proclamation to "Declare that an adequate shipping service has been established."

To the mind of the layman this wording seems to present an almost impossible condition. How in the name of Heaven can any one expect American shipowners to establish "an adequate shipping service" to the Philippines without having some assurance that a proclamation will be issued. Possibly our ignorance of legal phraseology may put a wrong construction on this clause in the existing law, but there is no question in the minds of American owners but that this much desired provision of the Jones Act should be placed in operation at the earliest possible time. The Marine Congress, it is hoped, will add the weight of its influence to bringing this matter to a conclusion.

PASSENGERS ON CARGO VESSELS

Section 26 of the Act contains authority to carry not more than 16 passengers on any American cargo vessels without being held to be "passenger vessels" or "vessels carrying passengers" within the meaning of the inspection laws.

This has been taken advantage of in but very few instances, but there is no doubt but that when trade picks up and permanent routes are established, this provision of law will be of decided advantage to American ships. Business people must go where goods are to be sold, and oftentimes there may be no established passenger service to foreign ports where it is desirable to extend our foreign trade.

THROUGH PREFERENTIAL RATES TO BE ALLOWED ONLY WHEN PROPERTY OR PASSENGERS ARE CARRIED IN AMERICAN VESSELS

Section 28 of the Jones Act makes it permissible under certain conditions for the Interstate Commerce Commission to give preferential railroad rates on passengers and merchandise arriving in or departing from American ports.

This has as yet not been enforced and in the opinion of many experts can be made very advantageous to American ships. It is naturally a very complicated matter, and one in which there can be many conflicting elements. The common carriers on land do not welcome any reduction in rates, which they consider at present to be none too remunerative for the burdens placed upon them by other requirements of law. The whole subject is now being given rapt attention by officials who are interested, and out of their conclusions may yet come some reductions which will benefit shipping.

DISCRIMINATING CUSTOMS DUTIES AND TONNAGE TAXES

Section 34 of the Jones Act was the one most relied upon to furnish the inducement for private owners to operate vessels in the foreign trade. In it the President was "authorized and directed" to serve notices of intent to nullify or amend any treaty with any foreign nation, which conflicted with our right to impose preferential tonnage taxes or import duties on all but American vessels bringing goods to our shores.

Under a similar policy in the early part of the last century, the American merchant marine was fostered until it became very prosperous. A similar result was expected under the terms of the Jones Act. President Wilson and President Harding both considered that under the existing unsettled condition of world affairs it would be unwise and inexpedient to serve such notices, and hence to date it has not been done. This lack of action serves to draw attention to the fact that Congress does not get very far in "directing" our chief executive as to what he shall do in affairs of diplomacy.

Whether President Coolidge will agree to the annulment of these treaties remains to be seen, and perhaps he would be glad to hear the opinion of the Marine Congress on the subject.

Whether the treaties are modified or not has no bearing on the subject of preferential duties in the indirect trade. That is, for example, if American ships and German or English ships are in competition for trade from Brazil to the United States, there is nothing to prevent Congress from giving American ships preference, so far as customs duties are concerned, of a sufficient amount to allow American vessels to compete. Brazilian vessels would, of course, have to be given the same treatment which we accord our own vessels, and which would be eminently proper. As many important export markets of the future are likely to be with countries having little or no shipping of their own, legislation of this kind would be very valuable and should be urged by the Marine Congress, if it is again decided not to apply the principle generally to all nations.

While the above are the main legislative enactments from which benefits may be obtained, if they are invoked, the following are some of the matters needed which have been discussed as of value, and which it is hoped will be enacted into law as soon as possible. They may very well be discussed at the Marine Congress and be the subjects of finite recommendations.

RESTRICTIONS OF 50 PERCENT OF IMMIGRATION TO OUR OWN SHIPS

This is a much desired piece of legislation for the benefit of American vessels in the North Atlantic routes, as it is from European ports that the great bulk of our immigration comes. The necessary authority was contained in the original subsidy bill, and there was very little opposition to it. There was, however, some friction in the House of Representatives, as to whether or not the Committee on Merchant Marine and Fisheries, which handled the subsidy bill, should have jurisdiction over this particular item, where there was a perfectly good Committee on Immigration which claimed all such matters.

No matter how it is handled in Congress, it is of such an equitable character that it should be passed in the new Congress, as one of the costless means of benefiting our merchant marine in foreign ports.

GOVERNMENT EMPLOYEES MUST TRAVEL ON AMERICAN SHIPS

This clause was also included in the subsidy bill, and of all the many items in that ill-fated measure, it was the only one to which there was given unanimous approval. In itself it will bring no appreciable revenue to American ships, but psychologically it will be of great advantage. The example set by many high officials of the diplomatic and consular service in traveling to and from their foreign stations on alien vessels, when, as has frequently occurred, they could have traveled on ships flying their own flag, has been, to say the least, abominable. The examples they have set have had a very damaging effect on the action of American citizens, who have given foreign vessels preference in traveling abroad.

During the past summer and spring there have been an unusual number of United States senators and congressmen who have gone to Europe to study conditions over there, and to their everlasting credit, almost without exception they have selected American vessels on which to make their pilgrimages, and paid for the passages out of their own pockets. There is therefore very little doubt but that legislation will be enacted at the next session of Congress, making it mandatory for those who travel abroad at public expense to patronize American vessels wherever possible.

REVISION OF NAVIGATION LAWS

This subject is one of great importance to the successful operation of our merchant marine. Many tomes have been written on the subject, and much oratorical effort expended. Many ill-advised proponents of shipping have contended that such revision was all that we need to place our ships on the seas and keep them there. As a matter of fact, if we adopted the Merchant Shipping Act of Great Britain in toto, we would come very far from meeting success in the rivalry on the ocean; while there are certain phases of the English shipping laws which are not at all applicable to our ship operation, the present navigation laws and Steamboat Inspection Regulations should be so amended that American vessels will have no more restrictions than British vessels.

These laws and regulations have been in process of revision by Shipping Board experts for many months, and the authorities at Washington should be urged by the Marine Congress to have the revised draft submitted for action by our lawmakers as early as humanly possible.

As a general rule the less laws and regulations we have the better it will be for all concerned. The classification society should be depended upon for much of the onerous and time-consuming inspections now demanded by our Government. American vessels have more inspections than the vessels of any other nation. This not alone is provocative of delays, but in the end much money is wasted in the annual inspections of cargo vessels.

NAVAL RESERVE

It has been suggested that one way to overcome the differential in cost of crews on American vessels engaged in the foreign trade is to detail enlisted men from the authorized personnel of the Navy to man these ships under merchant officers. In view of the value of the training they receive in the operation of merchant vessels, a duty they would have to perform in time of war anyhow, it is proposed that one-half their pay be given from the naval appropriation, and the other half to be paid by the shipowners. This would effectually overcome the difference in wage costs and provide real patriotic American crews—so much needed for an efficient merchant marine engaged in the foreign trade.

How Our Navigation Laws Handicap American Ships

Codification and Revision of Marine Laws Has Received Wide Endorsement—Recommendations Filed by Special Committee on March 5, 1920, Should Be Given Consideration

By V. G. Iden

IT is generally conceded by all students of shipping that one of the fundamental handicaps under which the American merchant marine operates is found in the sundry federal laws which have been enacted to regulate shipping. In a democratic country such as the United States it has been comparatively easy for first one and then another political group to have an act put through Congress. Some of these have been "log-rolled" and some have been put through on a "trade." Politics is a tricky master and many a well-meaning idealist has found it necessary to compromise in order to accomplish even a little of what he thought was good.

Furthermore political complexion has first taken on one turn and then another. Colonial restrictions enacted by European powers resulted in counter acts by the United States. Graft resulting from the mistaken forms of state aid granted after the Civil War brought about a reaction and a counter of restriction. The sinking of the *Titanic* caused a hysteria that resulted in further restrictions on the building and equipment of ships. Then labor obtained the ear of Congress and the La Follette law was enacted.

All comes down to the one thing: That the navigation laws of the United States have, for the greater part, been the result of outside influences rather than from any urging within the ranks of merchant shipping. Little of such laws was intended to encourage American shipping, but mostly the laws were designed to prevent American shipowners from doing some specific thing. The imposition of restrictions is always a burden, no matter whether they are warranted by humanitarian motives or not.

WAR CAUSED AMERICA TO ACT

It was not until the Great War with Germany occurred that the United States awoke to the necessity of doing something and of doing it in a hurry. Naturally within such a brief space of time available it was impossible to undo all the statutes that had blighted American shipping during the previous decade. That method of recouping our maritime power was not to be thought of, so it was decided to enact the United States Shipping Board law. That law created a body which was supposed to study the shipping problem and to draft regulations and recommend to Congress new laws to aid in the upbuilding of our marine. By attaching the shipbuilding provisions to that law, which were necessitated as a war emergency, the issue was complicated.

Ever since that time the intent of the original Shipping Board Act has been clouded by government ownership and the urgency of getting some tangible good out of the fleet. A subsidy was proposed in order to encourage private operators to take over the fleet, but Congress refused to enact it. With the closing of that issue the atmosphere is once more being cleared and the time is now ripe to bring back to the attention of the public the fundamental handicaps on the private operation of merchant ships found in the navigation laws.

COMMITTEE TO STUDY NAVIGATION LAWS AUTHORIZED

On September 4, 1919, the United States Shipping Board adopted a resolution authorizing the creation of a body of

practical shipping men to study the subject of our navigation laws and to report thereon to the board. The committee was subsequently created with this personnel: P. A. S. Franklin, chairman, J. Parker Kirlin, Homer L. Ferguson, H. F. Alexander, David T. Warden, Alfred Gilbert Smith, Eugene E. O'Donnell, Andrew Furuseth, William S. Brown, Darrah de Lancey, and A. N. McGray, all men well known in the shipping industry. This committee filed its report with the board on March 5, 1920. While the report of the committee was never made public it is generally acknowledged that parts of its recommendations were incorporated in chapters which were primarily compiled and proposed to Congress for the new navigation code. Inasmuch as no comprehensive codification and revision of these laws has as yet been approached, a survey of the findings of this special committee remains the best measure of the shortcomings of the existing laws.

The present navigation laws and the regulations thereunder are to be found scattered through a large number of volumes of statutes and regulations, passed at different times. Numerous amendments have been made which repeal all acts and parts of acts inconsistent therewith. This forces a comparative study of the various statutes and regulations, if it is to be determined just what the present law or regulation on any particular subject is.

A technical committee, it has been suggested, should be authorized to draft a consolidation of the revision of the laws into a single code. It has further been suggested that the authority to make regulations under such a projected code should be vested in a single administrative body, or department of the Government. At present the authority to issue regulations under laws on merchant shipping is scattered among a number of boards and bureaus.

The reasonableness of these demands is readily apparent and in principle has been endorsed by the Government. It remains to see that the codification is made and enacted by Congress. And if the proper amendments are enacted in that code the American merchant marine, in the matter of protective law and regulation, should be placed upon a parity with the merchant ships of other maritime nations of the world.

RECOMMENDATIONS OF THE SPECIAL COMMITTEE

Further recommendations made by the special committee relate to the enactment of a load-line law; the adoption of a resolution calling for an international conference to draft rules for the prevention of collision at sea, and the approval of the Brussels treaty dealing with the subject of liability for collisions. While these subjects are but concomitant, they nevertheless have a bearing upon the main subject and their adoption would tend to make the United States a leader in things maritime. It must also be recognized that the committee making these recommendations was one composed of representatives of labor, shipowners, operators, shippers. They represented all different business complexions. The recommendations are non-partisan and were made in the best interest of the great industry of merchant shipping under the American flag. Under such circumstances it is difficult to understand why the United States Shipping Board would hesitate for a moment in passing the recom-

mendations on to Congress and Congress halting for a moment in executing them into law.

Commerce by water is a problem which does not necessarily embrace that of a merchant marine. Water commerce depends upon the encouragement that a particular locality gives to ships to enter and clear the port. Port regulations imposed in the form of harbor dues, tonnage taxes, lighterage, dock rentals, pilotage, customs inspection, health regulations, go to make up the popularity or unpopularity of a port. Ships will naturally seek out those ports through which they can clear their passengers and cargoes with the least expense and with the greatest expedition. Those ports have the greatest steamship services no matter what flag predominates on the high seas.

It is this fact which explains to some extent why certain ports of the United States appear to be favored over others in the way of steamship connections. The fact that some ports have, in the past, been given what was thought inadequate steamship services prompted appeals for Government assistance. The United States Shipping Board, being a Government body, was naturally responsive to political importuning, and services were established out of ports which would not otherwise have boasted of a marine.

ECONOMY OF OPERATION AND NATIONAL PROTECTION DETERMINING FACTORS

But port services and a marine flying the American flag are two entirely different things. The ocean is free and trackless, except to the extent to which custom has evolved certain general trade routes. These routes have been predicated upon the place from which commerce originated and the destination to which it was going as well as upon the availability of ports through which that commerce flowed. The flag which ships fly is primarily determined by the economies of operation and the national protection permissible under that flag. American capital has invested freely in vessels flying the flag of nations other than the United States, and will continue so to invest until the navigation laws of this country are revised and codified so that all artificial restrictions are removed and our ships are given as much freedom of action under the laws as are the vessels of other nations.

If it is the popular desire to have American money invested in ships which fly the American flag, then it should be the popular desire to have statutes which encourage such investments. Liberalizations of the laws are essential, and it has been shown that such liberalization is possible without in the least destroying the safeguards to the public which our laws should be solely concerned with. A detailed study of the existing laws will show how wide of the mark they have gone.

TONNAGE MEASUREMENT RULES

Rules of admeasurement are issued by executive action under the statutes. These rules are drafted by the Commissioner of Navigation and applied by him in the manner in which he decrees the law directs him. Until the World War the rules so promulgated seriously discriminated against American ships inasmuch as certain spaces were included in the total tonnage of a ship which were not included under the admeasurement rules of other nations. It was claimed that the American tonnage was approximately five percent larger than would be the tonnage had the ship been measured under the British flag, and was even larger in comparison with German admeasurement. This meant that port fees and other taxes which are based upon the tonnage of a ship were larger in the case of American vessels than in the case of vessels flying the flag of another nation.

In respect to admeasurement, however, the correction was comparatively simple. The executive rules were changed in 1915, after the outbreak of war so patently brought to the

attention of Washington officials the necessity of considering the claims of steamship owners with more grace. Our rules now permit the exception of certain spaces subject to certain construction provisions which are clearly set forth in the existing rules. It now appears that builders in the United States are taking advantage of the opportunities offered for deductions, thus giving American ships substantially the same advantages that are enjoyed by vessels of other nations.

In 1919 the Commissioner of Navigation issued a ruling that all double-bottom spaces may be eliminated from or not considered at all in the calculations of the gross tonnage of ships. It has also been pointed out by practical naval architects that Articles 39 and 40 of the commissioner's regulations clearly provide for the deduction of propelling machinery spaces and for the addition of certain air and light spaces which entitle the vessels to a deduction of 32 percent of the entire gross tonnage. It has been recommended that the attention of owners and builders be drawn to these provisions in order that, by taking advantage of the new regulations in the preliminary designs of the ships, they may be allowed deductions which will materially reduce the net tonnage and will practically put ships under the American flag on a par with those of other maritime nations.

It would appear from these simple examples drawn from the more modern interpretations given our navigation laws that some of the serious inequalities have been removed. But it will be observed by reference to the rules that if the propelling machinery spaces are not larger than absolutely necessary for certain types of machinery now being installed, the question arises whether or no they should be made larger by increasing the light and air spaces without encroaching on the cargo spaces. In the case of bulk ships this would make a material difference in freight earnings, due to the extra cubic capacity, whereas in deadweight ships the loss in cargo space would be negligible.

MEASUREMENT COMPLICATED BY DUAL CONTROL

The law specifies that the measurement of vessels shall be done by the surveyors of customs, and further directs that the Commissioner of Navigation shall have supervision of the laws relating to the measurement. Here we have two executive departments of the Government concerned with the one thing, a situation which is always conducive to complication and inconvenience. Common sense dictates that both the "personnel" as well as the "supervision" in this case should be under the Commissioner of Navigation alone. It has furthermore been suggested with good logic that the country should be divided into "admeasurement districts" under separate supervisors, directed through one central office.

According to shipping men a load line law is especially desirable. In consultation with leading naval architects, shipowners and operators and others concerned, a model act has been proposed which has already been before Congress. This, it is felt, should be incorporated in the statutes.

It would appear that the shipping world is not averse entirely to regulation by Federal authority, although it is averse to regulations which are based upon antiquated needs and directed by statutes which should be killed by Congressional action inasmuch as they are already dead through modern usage. The law, for instance, directs that there shall be an annual hydrostatic test of marine boilers. This means that the boilers of steamships shall be subjected to a specially extra hard strain each twelve months. It would be much better to accept a test made under scientific conditions at the factory when the boiler is built and provision be made for the acceptance of a report from the classification society at the periods of survey. In case a vessel is not classed by a recognized classification society, the survey period should not exceed three years, at the end of which time the application of the hydrostatic pressure should be made if in the dis-

cretion of the surveyor or inspector this application is found necessary. A dry examination could be made yearly or oftener, if thought advisable.

Likewise the steam-pipes and boiler auxiliaries could be tested at the plant or when installed on board the vessel. A modification of the regulations in this way would be of great assistance to American ships and would, in a manner, be a step tending to cooperate with, instead of to hamper, American steamship operations. This revision would remove any possibility of prosecution under the law. Shipping men are not so narrow as to show hostility to all regulation but they want that regulation so applied as not to penalize their operations. For instance the law requires the use of fusible plugs on marine boilers. These entail an added expense but are demanded in the name of safety. Steamship owners are not opposed to this but they do criticise the numerous and perplexing regulations issued on the subject of such plugs.

NO DISCRETION ALLOWED INSPECTION SERVICE

The spirit which prompted the enactment of many of the navigation statutes of the United States was such as to evidence an inherent hostility toward shipping. That is undoubtedly why so much criticism is heard of the mandatory character of the legislation under which the Steamboat Inspection Service operates. That is also why no discretion is left to the officers responsible for the enforcement of the laws. British law permits elasticity as does the maritime law of most any other nation.

Our merchant fleet is composed of many diversified types of vessels engaged in various kinds of navigation. It is difficult to draft any mandatory type of law for general application under these circumstances. The earlier laws, which still remain a part of the statutes, related to vessels operating on inland waterways. And many of the statutes, while somewhat more modern in their intent, still could not be amended satisfactorily to cover the various types of vessels which developed from the early steamboat and which now make up our diversified merchant marine.

In the revision or recodification of the statutes, therefore the request of the steamship men that this basic fact be kept in mind appears to be wholly reasonable. They request:

First: That all steam or motor propelled vessels be classified, having regard to the particular types and trade conditions.

Second: That the laws governing classification and inspection be revised, having regard to the particular types and trade conditions.

Third: That the revised legislation give to the administrative office discretionary authority without sacrificing safety.

Fourth: That all seagoing, lake, bay and sound vessels of more than 200 tons be built under the rules and survey of the American Bureau of Shipping or similar classification society.

Fifth: In the division of vessels into groups, the rules of the Board of Supervising Inspectors and the American Bureau of Shipping will be helpful in defining the various types. As the laws governing the Steamboat Inspection Service principally cover safety of life at sea, some of the present statutes may reasonably apply to all types; in the main, however, specific statutes covering each particular group will be found desirable.

SUGGESTED THAT CLASSIFICATION SOCIETIES MAKE SURVEYS

It has been suggested that cargo vessels should be subjected to inspection at the survey periods by the classification societies abolishing the annual inspection by the Steamboat Inspection Service, which would place our laws upon a parity with those of England in this regard. At least a survey every eighteen months would appear to be adequate. All repairs and structural changes could be referred to the classification society for action at the survey period, or if considerable deterioration has actually taken place in the vessel's hull, boilers or machinery, prompt action could be taken if deemed advisable by the classification society. Passenger vessels could be subjected to an annual inspection, but the application of the hydrostatic pressure to boilers should only

be done at the survey periods and all questions of reconstruction should be passed upon by the classification society.

The imposition of so much authority in the classification societies is wholly warranted by the developments of recent years. These societies have a reputation at stake and are believed in many high quarters to be more responsible than any group of inspectors which the Government may put out by political appointment. "The time has come," said a memorial to Washington signed by the leading American shipping men, "when we might give formal recognition to the functions of the classification societies and in our opinion the closest harmony and thorough cooperation should exist between the inspection service and such societies, to the end that a successful, vigorous and efficient merchant marine may be developed." In that thought responsible trade authorities agree. The insurance companies will place their risks upon the reports of such societies and the Federal authorities might as well profit from such a practical endorsement.

A revision of the statutes made in this spirit would be of great assistance to the American merchant marine. It would be an encouragement to private ownership and operation instead of a discouragement. Furthermore these recommendations, which have so long been pending before the Shipping Board, have not only the endorsement of the American owners but likewise the endorsement of the representatives of labor.

The revisions suggested would not relieve the steamship owners of their responsibility to maintain the structural features of ships to a point that is entirely adequate for all purposes of safety. The revisions would merely relieve them of arbitrary rulings which place them at a disadvantage in comparison with the merchant ships of other nationalities, and would limit the application of such laws to times when it would interfere least with the business of the ship.

LAWS RELATING TO MANNING OF VESSELS

But a codification of the navigation laws should not be limited only to questions of admeasurement and survey, but should also embrace all the laws which have to do with the manning of ships. Our laws relating to personnel aboard ship are such as to conspire against the competency of American officers instead of jealously guarding such competency. It speaks well for the rank and file of American sea officers that they have maintained the morale and high standing they actually enjoy in the face of such conditions, when, as a matter of fact, it would be comparatively easy for incompetents to receive high rating under our method of examining applicants and of granting licenses.

It has been recommended that the laws be amended so as to impose in the Board of Supervising Inspectors the power to make rules for the examination of applicants, to determine the class and character of licenses, and formulate uniform examination papers for the use of the local inspectors who shall examine the applicants on such papers. The supervising inspectors should also have the power to revise or alter the examination papers as time and conditions may make advisable.

Under the present law applicants for licenses are examined by the local inspectors of the several districts. The examination may be written or oral. The local inspectors in each district determine the scope and extent of the examination. The result is that the examinations in the various districts are not uniform, varying in scope and difficulty according to the views of the local inspectors in each of the districts. The examinations to obtain licenses in some districts are much less difficult than in other districts. The result is quite unsatisfactory. There should be as nearly as possible a uniform standard examination required in all districts. This result could be best obtained by giving to the supervising inspectors the power to formulate examination papers on which the local inspectors examine the applicants. The local inspectors

might, in case they see fit, supplement the uniform examination papers by further examination, oral or written, as they think best, to satisfy them as to the qualification of any individual applicant. This power would take care of cases where, for any reason, an applicant may have obtained advance information of the examination questions.

Once a license is granted the law provides that it shall remain in force for the term of five years. Instead of that the license should be permitted to run only during good behavior of the officer holding it. The re-examination of masters, mates and pilots is limited under the present practice to sight, color vision and hearing, yet the license, if the applicant has passed these tests, is re-issued completely as though there had been a re-examination on the merits.

The re-examinations as now conducted are inconvenient, and consume much of the time of the shore leave of the applicants. The re-issue of licenses, which occupies a large part of the time of the local inspectors in certain ports, appears to be quite unnecessary, and to constitute an inconvenience both to those who grant and to those who receive the licenses. It has been recommended that the law be amended so as to provide for a test or examination as to eyesight, color vision and hearing which every master, mate or pilot licensed would be required to pass at least once in every five years. This examination should be made by the officers of the Public Health Service and the licensee should report the result to the inspectors, thus taking from the inspectors the entire burden of re-examining officers. Under this amendment the inspectors should be given the power to discipline as for misconduct an officer who does not report the result of the examination in accordance with the law.

LAW SHOULD INSURE GOOD MORALE

Not only should the law be drafted with the idea of insuring the competency of officers, but it should also be drafted to insure the morale of a ship's crew. This means that authority should not be undermined in any way whatsoever. The statutes should be amended so as to place on the master alone the duty of reporting to the inspectors all accidents or occurrences producing serious injury to the vessel, instead of placing the duty on all officers as is the case under the present law. It seems obvious that any accidents or occurrences producing serious injury to a vessel would be within the knowledge of the master. It would tend to decrease discipline and order lines if officers or engineers were under duty to report directly to the inspectors matters within the knowledge of the master. The statutes should provide for the suspension or revocation of licenses for failure to perform the duty imposed by such an amendment, as such dereliction would clearly be construed as misconduct.

The present law gives the local inspectors power and imposes upon them the duty to investigate all acts of incompetency or misconduct committed by licensed officers, and also to examine and try officers after such investigation has been made and charges have been preferred against them. It has been recommended to the Shipping Board that this provision of law is objectionable for these reasons:

First: It violates all principles of justice by making the same person or body both the prosecutor and the trier of an officer.

Second: An officer summoned before the Board of Local Inspectors sitting as a board of investigation is not given the opportunity or the right to be represented by counsel which is also in violation of our well-recognized standards of justice.

Third: In some of the districts such as New York and Chicago, a very large part of the time of the inspectors is occupied by the examination and trial of officers, which very greatly interferes with the execution of their other duties.

Under the present law as now administered, an officer who has committed an act which has been complained of, is summoned before the local inspectors and interrogated by them. He is not represented by counsel, with the result that information or evidence in proof of his innocence of the acts complained of is not elicited. This is obviously unjust.

Therefore, if the local inspectors see fit to prefer charges, the officer is brought to trial before the same inspectors who have investigated the charges against him and evidence taken on the preliminary investigation is used against him. It is clear that an officer cannot obtain a fair and impartial trial before a body who has already considered the evidence and preferred charges against the man. This procedure is as wrong in principle as though a man charged with crime should be tried before the grand jury that indicted him.

It is important that the investigation of charges preferred by the investigating body should be performed by or had before different officers or bodies. Therefore it has been recommended that the law be amended so as to provide that the local inspectors, after investigating acts or complaints of incompetency, etc., shall prefer charges and file them with the supervising inspector of the district, who shall convene a trial board consisting of three local inspectors, chosen from local inspectors' districts within the general inspection district, other than those who have taken part in the investigation; that such a trial board shall, after due notice, proceed with the trial of the case on testimony adduced before it, other than testimony taken upon the investigation, and that if the majority of the trial board is satisfied that the officer on trial is guilty of the offense charged, and shall recommend that his license be revoked, suspended or reduced in grade for such time as may be proper, the recommendation be transmitted to the local inspectors who preferred the charges and that they shall execute the recommendation.

MORE EQUITABLE PUNISHMENT LAWS DESIRABLE

Under the present law the inspectors have not the power to reduce a master or officer to a lower grade, as a method of punishment for misconduct. The only power the board has is to revoke or suspend the license. In case an officer is guilty of some offense for which his license should not be revoked, the only alternative that the local inspectors now have is to suspend a man's license, during which time his means of livelihood are taken away. This may in many cases be a very extreme hardship on the officer, whereas, if the local inspectors punish the man by reducing the grade of his license for a certain period of time, the officer could be adequately punished without taking away from him his means of livelihood.

The codified statutes should aim in every way to elevate the station of ship officers. That should be the animating spirit with which the laws should be rewritten. Consequently it is just as objectionable to have upon the statutes a provision of law which tends to make spies and sneaks of seamen as it is to make possible easy graft in the granting of licenses. The present law provides that one-half of the penalty for which a vessel shall be liable is to be paid to the informer. This, obviously, should be repealed, and the statutes should provide that the vessel may be seized only by leave of the United States. Such an amendment would obviate the possibility of the use of the vessel being unduly interfered with by some informer acting on his own initiative and actuated by a desire to recover one-half of the penalty.

Amendments to the navigation laws such as these, especially inasmuch as they have received such wide endorsement by all who have the least direct interest in the industry, warrant courteous consideration. A memorial to the Shipping Board asking for their consideration was filed on March 5, 1920. That memorial is now more than three years old. Nothing final and complete has been done. Still the shipping world struggles along under handicaps which might so easily be raised by legislative action. The arguments advanced for this revision and codification of the statutes are all valid. They especially commend themselves inasmuch as the revision will not redound to the detriment of the public but will actually enhance the interests of the merchant marine and thereby create a better agency to serve the public.

What Vessels Are Needed to Give the United States a Well Balanced Merchant Marine?

Will the Vessel Pay Is the Question That Must Be Answered in Determining the Character and Number of Additions to Our Fleet

By Joseph W. Powell

Former President, United States Shipping Board, Emergency Fleet Corporation

OF the various definitions of the word "balance" that appear in Century Dictionary the one that most nearly fits this application follows: "To bring into a state of equality."

The term "well balanced merchant fleet" has been used so often that it has been accepted as having a definite meaning, but a moment's reflection shows that for this to be true some standards must first be established; without this the term is meaningless.

The unanswerable argument for a merchant marine is that the national defence requires it as an auxiliary in time of war and without such aid our naval and military forces are impotent. Many other reasons may be debated, but this is axiomatic.

The next most powerful argument, to my mind, is that an American merchant marine is necessary to the proper expansion of our overseas trade. If this is accepted, a well balanced fleet must have sufficient units of various types to meet the trade requirements of the country. In fruit steamers, for the fleet under this flag, there must be tonnage to meet needs in this special trade which must be sufficient to hold America's share against the world. In oil tankers there must be enough to carry our petroleum business and to protect it against the upsets that might result from a war time withdrawal from our trade of all bulk tankers under belligerent flags. For passenger service there must be vessels of number, design and speed to meet the commercial needs of the country for communication in its foreign commerce. The United States cannot afford to have its commercial agents travel to Buenos Aires from New York, via Southampton, nor to Australia via England and the Mediterranean, nor to have this communication interrupted when other nations are at war. These ships, to meet the military and commercial needs, must *average* in size, speed, accommodations and economy, at least equal to the similar vessels of the competing nation.

WHAT A WELL BALANCED FLEET SHOULD PROVIDE

The ideal "well balanced merchant marine" that "brings into a state of equality" the various elements of that fleet, should therefore provide:

(1) Vessels of all types in sufficient numbers to meet at least the minimum of the nation's probable need

Is a "Well Balanced Merchant Marine" One That

—will meet all the war time needs of the Army and Navy by providing ample transport accommodations and ample fuel and provisions and other supplies?

—is so proportioned as to be suitable to carry some established proportion of each kind of ocean commerce, say one-half the passenger trade, one-half the fruit business, one-half the bulk cargo trade?

Would fleets meeting the above requirements be "well balanced" whether speeds were high or low, whether vessels were steam driven or fitted with internal combustion engine, whether they were old or new?

Would a fleet "well balanced" for Country A be "well balanced" for Country B?

in times when it is at war.

(2) Vessels of all types to carry on a reasonable proportion of its sea borne foreign commerce with especial regard to conditions when other nations are at war.

(3) These vessels must on the average at least equal the average of the competitor nations in design, speed, accommodations and economy.

Now no nation ever had a "balanced merchant marine" nor will such a one ever exist in this imperfect world. But with accepted principles upon which to base comparison, it is possible to draw conclusions as to the present complexion of the United States fleet. Even so, each element must be considered by itself and with not much regard to the other elements.

I do not grant, for instance, that we are now long on tanker tonnage. The recent California oil flood has filled our fleets which are today necessary to meet the nation's needs. Had less tankers been available we might be seeing foreign flag vessels plying between American ports. On the other hand, there will be general agreement that in slow, bulk cargo vessels we have a surplus beyond any possible need that many will believe should be broken up, to speed the day when world requirements and world tonnage may again come into equilibrium. Of the other elements, passenger ships, refrigerator vessels, etc., each must be measured by the accepted standard to determine what changes in its present units would produce this ideal fleet.

However, only one practical consideration finally influences this situation. Those units will be added to the fleet that offer chance of satisfactory return on the money invested. Except in so far as Government aid—now not very imminent—may foster types to meet special national needs, this consideration, and this alone, will settle the character and number of additions to our fleet.

If the United States is to compete successfully with foreign shipping, it must have ships equal or superior to those operated by foreign nations in the respective trades, and this will require a building program covering the various types of high class ships in which our merchant marine is now so deficient. —W. F. Gibbs, President, Gibbs Brothers, Inc.

Fast Refrigerator Vessels Needed for South American Trade

By Stevenson Taylor, President, American Bureau of Shipping

WE seem to be amply supplied with freighters left over from the war program. It is necessary, however, to make many of them fit present day requirements, by modernizing the propelling power in order to obtain the greatest possible efficiency.

Additional medium sized passenger ships are necessary both for our foreign and coastwise trades. These can profitably be used in extending our ocean borne commerce and will form a much desired nucleus of transports for purposes of national defense.

Although our supply of tankers is sufficient for the immediate present, it requires no stretch of the imagination

to see that in the very near future additional tanker tonnage will have to be constructed.

We are greatly deficient in refrigeration facilities for overseas requirements. In my opinion there will soon be an urgent demand for such tonnage both in our intercoastal trade and in the trade between the two great American continents. The juxtaposition of climatic conditions make an interchange of seasonal vegetables, fruits and meats very desirable to comport with the rapidly changing standards of living. This can best be accomplished by utilizing comparatively fast vessels which are provided with large refrigeration capacities.

Both Passenger and Cargo Ships of Suitable Size and Speed Lacking

By Carl E. Petersen, Naval Architect, United States Lines

A BALANCED merchant marine for the United States necessarily implies a fleet of sufficient size, composed of vessels of various types suitable properly to carry a majority of our foreign commerce; that is, our imports, exports, passenger travel to and from the United States, and immigration. Under no circumstance, should we be dependent on foreign shipping.

A detailed study of our commerce reports will indicate the number and types of vessels we require. In a general way it may be said we are sorely lacking in (a) moderately high speed passenger and mail steamers, 600 to 750 feet in length; (b) combination passenger and cargo steamers, 500 to 600 feet in length of about 16 knots speed; (c) cargo vessels of 9,000 to 12,000 tons deadweight and about 12 knots speed; (d) refrigerator vessels of 14 to 16 knots speed and (e) cargo vessels equipped with Diesel engines for propulsion.

We seem to have sufficient tankers to serve our needs for

the present; this phase of the question can safely be left to the oil producing and transportation companies.

In the North Atlantic passenger service, with which I am familiar, American flag vessels are greatly in a minority. Especially do we need to augment our tonnage in this trade with suitable types, if we are to receive and to hold our rightful share of this traffic. Putting this in concrete form we require to obtain for this objective at least three vessels, 750-footers of 20 knots speed or over; two vessels, 700-footers of about 19 knots speed; and five vessels, 600-footers of about 18 knots speed. It must, of course, be recognized that before this additional new tonnage would be ordered that (a) construction costs will have to be materially lower than those at present obtaining; (b) the navigation laws will have to be favorably revised—or the Government will have to lend moderate aid to the owner to offset the higher construction costs and the restrictive laws.

To Build Ships, First Build Up the Trade That Requires Them

By Alfred J. C. Robertson, Naval Architect, The Munson Line

A MERCHANT fleet differs in every way from a naval fleet, but perhaps in nothing more than in its dependence upon the law of supply and demand. A naval fleet must be designed to meet contingencies which we hope may never arise, a merchant fleet cannot safely be built far ahead of the existing demand. If this had been generally realized a few years ago, we would have been spared the fallacy, still prevalent in politics, that a shipbuilding program could create a shipping business. Ships are only and always a means to an end, not an end in themselves, and the only permanent and satisfactory way of building a merchant fleet is by building up the trade which requires it. The Shipping Board is in the unfortunate position of having built a cart, without the horse to move it—and horses cannot be built!

Today a considerable amount of the world's carrying trade is being performed by vessels unsuitable to their present employment, and, as long as the world's trade is suffering from the present destructive influences, it is probably better to use what implements are presently available than to forge

new ones which may be ill adapted to the future which is going to emerge.

The time will come, however, and perhaps more quickly than we can adequately prepare for it, when the surplus of usable tonnage will be absorbed and it will become necessary to build for specific purposes.

The movement of freight is the backbone of shipping, and this country has a large surplus of freighters, but the war tonnage still available was built for the one purpose of transatlantic service, with the great majority of ships over 8,500 tons deadweight. As a consequence there is a lack of the smaller sea-going vessels which are so necessary for building up trade and are able to move in and out of harbors where drafts are limited.

Again, there are comparatively few ships on the American Registry built for specific purposes such as the carriage of coal or other bulk cargoes, or the movement of lumber, steel or refrigerated or cooled cargoes.

The rapid growth of inland trade has already thrown a burden on the railroads which is being increasingly felt,

whereas gasoline and other transport appliances have tended to make railroad investments less attractive than heretofore, so that there is little hope that they will be able to expand as quickly as the demands upon them are growing. It is therefore evident that more cargoes will have to move by water and that shippers will be willing to pay for the higher speeds necessary to compete successfully with the freight lines on land.

A great increase of travel for pleasure is one of the recent developments, and where ocean travel is for pleasure, luxury in all its forms is demanded. This tendency will without

doubt direct business to those firms with the most up to date passenger ships, and along this line of development much has still to be done.

No reference is made to any specific means of ship propulsion. There is no doubt that the Diesel engine is making rapid strides, but the use of any particular means of moving our ships must be decided by engineers, who will take into consideration all the economic factors involved in each particular case. Suffice it to say that the Diesel engine has already proved its right to be considered as reliable as any other means of propulsion at present in use.

Large Passenger Ships Should Be Built for North Atlantic Service

By E. H. Rigg, Naval Architect, New York Shipbuilding Corporation

WHILE others have been busy replacing war losses in the passenger carrying field we have made a beginning in that field with our "State" classes of ships, since renamed after the Presidents. These vessels form only a nucleus, they are backed up by a number of ex-German liners, many of which are getting on in years. Our first use for all these vessels, new and old, was as troop transports, though the war ended before the ships building could be put in service.

Our most noticeable lack is in ships fit for the North Atlantic service. None of the vessels that we have, outside the *Leviathan* and a very few other ex-German ships, is really suitable; they are all small for that trade and well as they may fit in as a beginning on our Pacific and South American routes, they do not stack up well alongside the vessels that ply the North Atlantic.

In 1921, before the Society of Naval Architects and Marine Engineers, in New York, the writer suggested that serious consideration be given to a class of ships about 750 feet long for North Atlantic passenger service. This type of ship is needed to give balance to our fleets and especially to work with the *Leviathan*.

In the Spanish and again in the late war, our lack of ships fit to carry troops was such as to cause the utmost anxiety to those responsible. In the case of the Spanish war, our shipping people know full well that we had to buy many entirely unsuitable vessels. Things were different in the late war, but not thanks to the suitable ships we had meanwhile built. It should be mentioned that such few transports of our own build as were available did their jobs well, some very well.

Briefly then, we need passenger ships of the larger class and particularly some running mates for the *Leviathan*, which is operated by the United States Lines as the flagship of the American merchant marine.

As time goes on our Pacific and South American routes, especially the latter, will need improved ships, designed for these routes. The many excellent foreign liners to South America will need counterparts from New York.

Our coastwise routes have not been strengthened materially, except in isolated instances, since the war began. Many new vessels have been projected, some have been laid down and put into service; this field would appear to offer scope for new and improved types of vessels when conditions as to building costs, etc., warrant laying down new keels.

Refrigerator ships are another lack. The California fruit trade would be materially helped by some intercoastal boats running via Panama; a passenger service also could be built up and maintained with the same ships. The Hog Island "B" type ships might serve here, if equipped with refrigerating machinery and insulated holds.

There will be occasional cargo boats of special types, but no general building of this class can be expected for a few years.

Oil tankers built and in service appear ample to handle the business now offering but this branch will need ships in the comparatively near future, especially if new oil-producing fields are opened up in South America.

Our inland water borne commerce is again being developed, and the new Erie Canal, the Mississippi and other water routes are being served by modern vessels, specially designed for the routes concerned.

Special Types of Vessels Needed for Special Trades

By Hugo P. Frear, Naval Architect, Bethlehem Shipbuilding Corporation, Ltd.

THE question of rounding out or balancing our merchant marine fleet is a vital one, if we are serious, as a nation, in our desire to keep it alive and also to take full advantage of trades which demand vessels of greater economy and in many cases vessels of special types. This has been a recognized and more or less discussed problem ever since the close of the war. Anything like a satisfactory solution will demand more favorable marine laws under which to operate and much faith, courage, time and no little financing. The following paragraph is quoted from the writer's discussion of Mr. E. H. Rigg's paper on "The Design and Construction of Passenger Steamers," read before the Society of Naval Architects and Marine Engineers in 1921.

"Our new merchant marine built during the war was not based on a prearranged, well thought out program, but on a hit or miss plan, resulting in an unbalanced fleet for either war or peace service, including a multitude of vessels worth less than scrap, and very few suitable for special trades. On this account it seems evident that passenger steamers and vessels for special trades are the ones shipbuilders must depend upon in the immediate future for new orders."

A large number of wooden vessels have been scrapped and a very few sold for restricted commercial purposes. It has also been suggested to scrap all useless vessels. If this were carried out intelligently, it would simplify the problem under consideration but would not balance our fleet. It is understood that a thorough survey has been made of the vessels

composing the Shipping Board fleet, but it is not known whether or not the full report will be published or how much assistance it would be in determining what ships fall in the useless class.

Many of the better type of the general cargo vessels could no doubt under more careful design be greatly improved upon both as to hull and machinery. Much thought and labor have been expended toward substituting Diesel engines in a great many of these vessels under conditions thought to be sufficiently favorable to insure their economic operation. These improvements, however, would not even balance this part of the fleet. There are too many small vessels, and too few fast freighters. There should be a greater proportion of the larger type of freighters capable of a sea speed of not less than 13 knots, for the quicker dispatch of high class cargoes.

When the old tramp steamer came into vogue there were comparatively few special trades or few trades for which this type was not generally accepted as being more or less satisfactory in meeting all ordinary requirements. There are now so many special trades that special types are necessary to meet the more exacting conditions. Among the special types that might be suggested to round out or balance our fleet may be mentioned the following:

- (1) Some faster general cargo vessels.
- (2) Faster cargo vessels with more cold storage space.
- (3) Fast fruit steamers for coast to coast trade.

- (4) A better type of lumber vessel.
- (5) Combination lumber and steel products vessel.
- (6) A few steamers suitable for carrying locomotives.
- (7) More passenger steamers.

SUCCESS OF THE SPECIAL ORE CARRIER

That special types pay is perhaps most strikingly illustrated in the case of the 21,000 deadweight Bethlehem patent type of ore steamers, accounts of which have been published a number of times. There are five of these vessels at present bringing iron ore from Chile. Their success has so thoroughly demonstrated the advantages of this special type of ore carrier that three more vessels of the same tonnage are now under construction and will soon be in commission. This special type of vessel is equally well suited for carrying oil, or any other liquid cargo, in bulk, copper, pig iron, steel or steel manufactured products or any kind of heavy dry bulk cargo.

These Bethlehem steamers are not only the best types for ocean ore carrying but are a good example of how a special design can be worked out so that the vessel will be at no disadvantage in many other trades. With this thought in view vessels can generally be designed so that while supreme for their intended special trade yet they are at no disadvantage in at least some other lines. There is frequently a tendency to hold off on vessels for special trades on account of an erroneous assumption that it might be uneconomical to employ them, during an emergency, in any other trade.

American Passenger Vessels Should Provide Accommodations and Service Similar to Those Found in Modern American Hotels

By H. F. Norton, Naval Architect, Newport News Shipbuilding and Dry Dock Company

IT has seemed to me that we have not yet on the ocean a distinctly typical American passenger ship. The Europeans gained such headway in building ocean going passenger vessels, that we have apparently attempted rather to follow in their footsteps than to develop distinctive types of our own. Even our coastwise passenger ships bear distinct evidences of having been copied after European designs, and of course, our present greatest pride, the *Leviathan*, while a very great credit to American genius and ingenuity in her complete rehabilitation, and while up-to-date and American in many respects, is necessarily European in her general arrangement. Also in her reconditioning, many of the European details were copied or restored.

After all, an ocean going passenger ship is a floating hotel, and since on a several days' trip the passengers have no particular business on hand except to entertain and amuse themselves, or to be amused and entertained, it perhaps parallels a resort hotel rather than a metropolitan one, but partakes something of the character of both. Such being the case, there seems no good reason why the American ships should not differ from European ships as much as our modern hotels do from European hotels. The modern American hotel usually has one large space where the guests gather to converse, smoke, write and listen to the music, rather than half a dozen smaller places devoted to various matters. There is usually not a smoking room for men only. Small card rooms and tea rooms which may be occupied by private parties are sometimes provided and are found a popular feature. A gymnasium with mechanical horse, trunk vibrators, and such playthings, is not an American institution for hotels or resorts. A more desirable and typical feature would seem to be a baseball, tennis and golf cage, which apparently might readily be provided on some of the

upper decks. Personally, if there were no opportunity for anything better, I should rather have see-saws, slides and swings in the open air, such as are provided for real American children.

No modern American first class hotel fails to have at least a private toilet and lavatory in a small separate space for each bedroom, and I believe the time is coming when no ship will offer a first class stateroom without at least similar accommodations, and if a lavatory must be put in a bedroom, it should certainly be of the good honest American sanitary type, with open plumbing and not have a lot of cupboards and other contraptions around it. The old hotel idea of three or four beds in a room at a charge of about 50 cents or \$1 per bed a night has gone to the scrap heap. The modern American ship should have for all first class accommodations, single and double rooms with at least private toilets, lavatories and large size clothes closets. These closets should be large enough readily to accommodate ordinary baggage. The rooms should connect for the accommodation of families or parties. There should also be a goodly number of rooms with private baths or showers, or both, and with private sitting room attached. All first class rooms should be large enough to permit the serving of meals in the stateroom, if desired, and every ship should be arranged for this service, similar to the modern American hotel floor service.

Such accommodations will, of course, require extra charges, but I believe that the extra charges will be cheerfully met as the advance hotel rates have been met and will more than pay for the extra space. The old two and three berth staterooms will be relegated to second and third class. The coastwise operators are beginning to see this, and it is an encouraging sign.

What Part Will Motorships Play in Our Shipping?

Conversion of Certain of the Idle Shipping Board Steamers to Motorships
Will Make the Nucleus of an Efficient Privately Owned Merchant Marine

By Angelo Conti*

ACCORDING to a statement recently issued, the following vessels remained under control of the Shipping Board, as of September 1, 1923:

TABLE I.—COMPOSITION OF SHIPPING BOARD FLEET				
	Operating or Spot	Laid-Up	Total	Deadweight Tons
Cargo	365	801	1,166	8,059,632
Tankers	19	20	39	331,434
Refrigerators	2	12	14	100,949
Passenger	30	3	33	
Transports	..	5	5	
Tugs	26	9	35	
Damaged and obsolete....	..	40	40	297,306
Total	442	890	1,332	8,789,321

As a result of the recently completed work of the Central

cost not exceeding \$100,000 per ship. Vessels of this class are all fitted with Scotch boilers and geared turbines.
Class D—Includes vessels of good design and competitive type but fitted with machinery that will require extensive renewal, in varying degree, and are desirable hulls for conversion to Diesel propulsion. Only the best built hulls in a fair state of preservation are included in this class, in order that they may be converted, at a reasonable cost, into competitive and valuable additions to the American merchant marine.
Class E—Vessels considered in general unsuitable for American flag operation.
Class F—Vessels of obsolete types, too old to be rejuvenated or too badly damaged to be serviceable.

The following table gives the apportionment of the vessels among the various classes:

TABLE II.—CLASSIFICATION OF SHIPPING BOARD FLEET															
Class	A		B		C		D		E		F		All Classes		Total
Status	Spot and Oper	Laid Up	Spot and Oper	Laid Up	Spot and Oper	Laid Up	Spot and Oper	Laid Up	Spot and Oper	Laid Up	Spot and Oper	Laid Up	Spot and Oper	Laid Up	
Lakers	...	24	...	116	...	...	...	12	...	11	...	163	...	...	326
Cargo	309	69	...	58	18	48	27	310	...	1	...	27	354	513	867
Tankers	8	12	1	2	10	...	...	6	...	...	...	13	19	33	52
Refrigerators ..	2	3	...	...	...	3	...	6	...	...	...	...	2	12	14
Total	319	108	1	176	28	51	27	334	11	164	...	40	386	873	1,259
Total for class	427		177		79		361		175		40				

Survey Committee of the Shipping Board, these vessels have been classified under the following headings:

- Class A*—Steel vessels of good design, well built, equipped with reliable machinery and deck auxiliaries, and capable of continuous operation with normal upkeep. The estimated cost of repairs varies from a maximum of \$15,000 for lakers to a maximum of \$35,000 for all other types.
- Class B*—Of the same type as Class A, but requiring repairs and overhauling in excess of \$35,000.
- Class C*—Ships of good type, with well built hulls in a fair state of preservation, but less desirable than A and B because of deficient machinery. The latter, however, could be replaced at a

*Consulting engineer, formerly manager technical department, Emergency Fleet Corporation.

In addition to the above, all vessels of special types are classed separately as follows:

- Army transports..... 5
- Passenger vessels..... 33
- Tugs

- Competitive units in good condition.
- Includes 3 laid-up ex-German vessels.
- Wood and steel.

Omitting from consideration all vessels of special types, Table II shows 1,259 ships of all classes. Of this number, the 40 of class F will soon be relegated to the scrap heap and of the remainder, 326 are lake-built. Of these lake-built vessels, 152 have medium draft ranging from 19 to 21 feet and, as they are well built and have reliable machinery, they should eventually be absorbed by

our coastwise or West India trade. The remaining 175 lake vessels have excessive draft for coastal service and are too small for successful trans-oceanic operation. They are, however, of good construction, and, if offered for world-wide sale at a reasonable price, it is likely that a substantial number of them would be disposed of to trades in no way competing with American interests. The remaining vessel of class E is a collier, undesirable, in her present condition, for American operation.

We need then consider but 892 vessels, of which 386 are in operation or held in readiness for immediate requirements.

The majority of the active vessels are engaged in foreign trade under the mandates of the Jones Act. Unless this very constructive legislative measure is repealed, and American vessels retired from overseas commerce, the greater portion of these 386 vessels will always be required, whether under government or private control, and with the adoption of suitable policies, they should eventually pass to private ownership.

Likewise, the 195 laid-up vessels of classes A, B and C can be considered as an immediate operating reserve.

The real problem therefore centers on the disposal of the 361 ships of class D. Comprised of generally well-built hulls of competitive type, totaling 2,646,823 deadweight tons, and obtainable at nominal prices, this class represents the largest portion of the world's tonnage most ideally suitable for conversion purposes.

The following table gives a breakdown of this class:

TABLE III.—CLASS D—CARGO TYPES: 349 VESSELS—2,565,662 DEADWEIGHT TONS

No.	Av. Dwt.	Length	Beam	Depth	Draft	Block Coeff.	Load Displ.	Bale Capacity
16	9,725	395' 6"	55' 0"	34' 11"	27' 0"	.796	13,350	452,750
9	9,526	402' 0"	54' 0"	33' 9"	26' 10 3/4"	.775	12,910	491,100
38	9,433	402' 6"	53' 0"	34' 6"	26' 5 1/2"	.783	12,620	456,680
76	8,735	401' 0"	54' 0"	32' 10"	25' 2"	.785	12,225	442,880
14	8,729	410' 5 1/2"	54' 0"	30' 0"	24' 1"	.803	12,260	417,780
17	8,636	410' 5 1/2"	54' 0"	29' 9"	24' 2"	.798	12,220	417,780
29	8,394	410' 5 1/2"	54' 0"	29' 9"	22' 11 1/4"	.804	12,195	415,000
7	7,651	380' 0"	53' 2"	29' 4"	23' 8"	.786	10,732	376,600
5	6,306	340' 0"	49' 0"	28' 7 3/4"	23' 1 1/2"	.802	8,835	256,120
2	5,940	341' 0"	48' 0"	27' 3"	22' 5 1/2"	.806	8,520	265,340
112	5,300	324' 0"	46' 0"	28' 6"	22' 10"	.783	7,615	226,150
8	5,273	324' 0"	46' 0"	27' 8"	22' 6"	.78	7,350	232,000

TABLE V.—CLASS D—REFRIGERATORS: 6 VESSELS, 38,974 TONS DEADWEIGHT TONS

No.	Av. Dwt.	Length	Beam	Depth	Draft	Block Coeff.	Load Displ.	Cargo, Cu. Ft.	Capacity, Refrigerated
4	5,589	340' 0"	49' 0"	28' 7 3/4"	23' 1 1/2"	.802	8,835	51,630	207,850
2	8,370	402' 6"	53' 0"	54' 6"	26' 4 3/4"	.783	12,590	51,630	307,870

The Class "D" vessels, therefore, can be summarized as follows:

Cargo	349 vessels	2,565,662 tons dw.
Tankers	6 vessels	42,187 tons dw.
Refrigerators	6 vessels	38,974 tons dw.
Total	361 vessels	2,646,823 tons dw.

Of this number 14 have geared turbines and Scotch boilers, 262 have various makes of geared turbines and watertube boilers, and 85 have reciprocating engines and watertube boilers.

The cost of the replacements needed to make these vessels reliable and economical may be gathered from the following estimates, which were obtained by informally submitting comprehensive specifications to several leading yards and ship repair plants:

To retube a main condenser of 2,500 horsepower.....	\$6,000
To replace unsatisfactory condensing auxiliaries.....	10,000
To replace a set of 2,800 shaft horsepower cross-compound turbines, install 200-degree superheaters and effect all necessary alterations	95,000
To replace 3 watertube with Scotch boilers in a 2,500 indicated horsepower reciprocating engine, install 125-degree superheaters and effect all necessary alterations.....	100,000
To replace 3 watertube boilers with Scotch boilers fitted for 200-degree superheat, as required for 2,800 shaft horsepower cross-compound turbines	110,000

The cost of replacing the various unsatisfactory items, therefore, would range between \$110,000 and \$215,000 according to the combination of machinery.

The question now logically arises whether the above enumerated replacements would be as well justified on the score of economy as they are from the standpoint of increased reliability. At the present time the majority of vessels in operation average a fuel consumption of from 1.3 to 1.5 pounds per horsepower; turbines and reciprocating engines alike; a few a little less but many somewhat more. This is not surprising as in the case of geared turbines each 10 pound drop in steam pressure means a loss of 1 percent, each 12 degrees of decreased superheat a loss of 1 percent, while a drop in vacuum from 28 to 27 inches entails a further loss of 3 percent. In the case of reciprocating engines the unavoidable losses due to the progressive wear of main valves and piston rings are most difficult to estimate and both types of steam installations are equally adversely affected by the skill of the firemen in controlling the efficiency of combustion, the progressive sooting up of the boiler heating surface, the loss of vacuum by air leakages and warm sea water and by the failure of the engineer on watch to curtail the use of auxiliary steam or to properly utilize the surplus auxiliary exhaust.

Most of the turbines in question were designed for 50 degrees to 75 degrees of superheat and a nominal steam consumption of 12 to 12.5 pounds per shaft horsepower, and, if replaced with ruggedly-built and reliable units suited for

200 degrees superheat, a saving of from 2.5 to 3 pounds of steam per horsepower would be quite possible. In the case of a 2,800 shaft horsepower installation operating 180 days per annum such a replacement would effect a fuel improvement of 6 tons per day, or a yearly saving of \$11,900, which is about 12.5 percent on the cost of replacement. Should the boilers also need renewal the return would be but 5.8 percent on the investment; improvement of the auxiliaries would further reduce it to 5.5 percent.

In the case of reciprocating engined vessels, the replacement of unsatisfactory watertube boilers with Scotch boilers an increase of superheat from 50 to 125 degrees would entail a saving in fuel of approximately 7 percent. This means that the daily fuel consumption of the average 2500 indicated horsepower installation, could be reduced from 35 to 32.5 tons, approximately \$5,000 per annum, which would return less than 5 percent on the investment.

While opinions may differ as to the possible ultimate savings, the above figures are based on actual average performance and represent a fair estimate of what may be expected with skillful operation. It should be noted, however,

**Design 1020—Typical Laker, Over 300 Available**

that the use of higher superheated steam will require more intelligent care and will be attended by somewhat greater maintenance costs.

In the case of Diesel machinery, however, the elements affecting the economy of operation are entirely automatic and largely independent of the engineers' operative skill. The admission of fuel is under governor control so that in bad weather dangerous racing is considerably reduced and power is developed with considerable uniformity.

The relative merits of steam and motorship operation being best demonstrated by actual performance, the following comparative data on two sisterships owned by the Shipping Board should be of particular interest.

One is the twin screw motorship *William Penn* fitted with Burmeister and Wain six cylinder engines, each rated 2100 indicated horsepower at 105 revolutions per minute and with engineroom and deck auxiliaries electrically driven from three Diesel generators of 65 kilowatts each. The other is a single screw steamer, operated by a quadruple expansion engine designed for 3200 indicated horsepower at 75 revolutions per minute. Steam is supplied by three Scotch boilers and the engineroom and deck auxiliaries represent good marine practice.

Barring a slight fining in the motorship's after body, both vessels have substantially the same lines, the same general dimensions, were constructed after the war by the same yard and can be considered as typical equivalents of the two methods of propulsion.

TABLE VI.—COMPARISON OF ACTUAL PERFORMANCE, STEAMER AND MOTORSHIP

Voyage Numbers	Ethan Allen		William Penn			Total or Averages
	54	1	2	3		
No. of ports called.....	21	18

Miles per ton of fuel.....	7.12	19.6		20.33	19.75	
Average daily fuel at sea.....	37.47	13.04		12.98	13.13	
Average daily fuel in port.....	22.79	.75				
Average daily fresh water.....	9.9	2.4				
Total cost voyage repairs engineroom.....	3,501	None				
Total cost voyage repairs deck machinery.....	None	393		185.00	578.00	

The *William Penn* has been in operation since September, 1921, has completed three long voyages and is now nearing the end of her fourth. The above record of her performance is, therefore, of added importance as it extends over a fairly long period. In the case of the *Ethan Allen*, only her last voyage has been given as her previous showing is not quite so good; her high port fuel consumption is explained by the necessity of maintaining steam up at Kobe and Shanghai for emergency purposes, otherwise it normally varies between 9 and 10 tons daily. In round figures the relative performance of the two vessels may be expressed by stating that on one ton of fuel the motorship covers a distance nearly three times greater than the steamer.

In addition to the above noted engineroom repairs at the end of the voyage \$2,245 was spent on the steamer's heating coils for the double bottoms and deep tanks, and \$1,000 for retubing and repacking her auxiliary condenser. These figures are quoted merely to show the greater maintenance costs obtaining with steam machinery by reason of the many additional channels of expenditure.

As regards relative earnings of steamers and motorships, any comparison of value would obtain only for sister vessels plying the same routes, which would be rather a rare occurrence. In the case of the two vessels whose performances were compared in Table VI, only such items as repairs, fuel and water consumptions, etc., could be included owing to the fact that as they operate on different routes their final net returns are not directly comparable.

Lacking actual data, we have, therefore, resorted to a specially prepared comparison for which we selected the

8,600 deadweight ton "Robert Dollar" type, for the reason that 136 such similar vessels are yet available for conversion. The following are the leading particulars:

Length between perpendiculars.....	410 feet 5½ inches
Beam, molded.....	54 feet
Depth, molded.....	30 feet 2 inches

Summer load draft.....	24 feet 1¼ inches
Summer displacement	12,200 tons
Summer deadweight	8,560 tons
Total bale capacity	437,300 cubic feet
Fuel oil, settling tanks.....	80 tons
Fuel oil inner bottoms.....	990 tons
Fuel oil deep tanks.....	600 tons
Total fuel capacity	1,670 tons
Reserve feed water, inner bottoms.....	190 tons
Reserve feed water, fore peak.....	130 tons

The basic data used in the following comparisons were obtained from actual performances of a number of Shipping Board steamers of the *Robert Dollar* or similar types plying the routes under consideration, but the consumption of fuel, water, lubricating oil, stores and maintenance of propelling and deck machinery were somewhat reduced, on the assumption that the vessels would be privately operated under the most rigid supervision.

	Coal Burning Steamer	Oil Burning Steamer	Motorship
Service speed, knots.....	9	10	10
Fuel at sea, tons per day.....	45	32	10
Fuel in port, tons per day.....	11	8	.6
Fuel lay days, tons per day.....	5	3	.25
Fuel at home ports, \$ per ton.....	8.55	11	14
Fuel abroad, \$ per ton.....	7.40	14.10	...
Lubricating oil at sea, \$ per day.....	4.00	4.00	5.70
Lubricating oil in port, \$ per day.....	1.00	1.00	1.50

The data used for the motorship were based on the performance of the *William Penn*. The converted vessel was credited with an additional 10,000 cubic feet of cargo space due to the elimination of boiler casing, saddleback, etc.; and her annual overhauling period was assumed to be approximately one-half the steamers: as no time would be consumed in lengthy boiler repairs. The same time in port for loading and discharging cargo and an annual allowance of five days for bad weather was used in all cases. The machinery maintenance charges were also assumed considerably lower for the motorship, the difference being accounted for by the extra cost of repairs to boilers, deck machinery, heating coils and steaming out of fuel tanks. The following table compares the engine department payrolls for the different types of machinery, based on the present revised schedule:

TABLE XI.—ENGINE DEPARTMENT PAYROLL

Rank	Monthly Wages	Coal Burn- ing Steamer		Oil Burn- ing Steamer		Motorship	
		No.	Wages	No.	Wages	No.	Wages
Chief engineer....	\$260.00	1	\$260.00	1	\$260.00	1	\$260.00
First engineer....	185.00	1	185.00	1	185.00	1	185.00
Second engineer....	165.00	1	165.00	1	165.00	1	165.00
Third engineer....	150.00	1	150.00	1	150.00	1	150.00
Electrician	150.00	..	..	..	..	1	150.00

Monthly total	19	\$1,765.00	13	\$1,345.00	8	\$1,127.50	
Total wages per annum.....	21,180.00	16,140.00	13,530.00				
Subsistence @ 65c. per day....	4,507.75	3,084.25	2,198.00				
Total wages and subhist.....	25,687.75	19,224.25	15,728.00				
Excess over motorship.....	9,959.75	3,496.25					

The comparative cargo carrying capacities for each route have been investigated in Tables VII and VIII, and a summary of operating expenses affected by the type of machinery will be found in Tables IX and X, all other expenditures having been omitted as they are substantially the same for both types of vessels. This assumption obtains only when equal amounts of cargo are carried; if the net additional earnings of the motorship need be computed all expenses

incidental to handling the extra cargo, such as stevedoring, brokerage, etc., should be deducted from the additional freight revenues.

The above conclusively proves the many inherent advantages of the motorship, but it should be noted that Diesel machinery, by reason of greater development costs and the higher grade materials and workmanship required in its construction, is considerably more expensive than a corresponding first class steam plant of equivalent power; the cost of an up-to-date Diesel installation being further augmented by the various electrically driven engine room and deck auxiliaries. This may be inferred from the following estimates for the conversion to Diesel propulsion of certain typical Shipping Board cargo steamers of varying sizes.

TABLE XIII.—ESTIMATED DIESEL CONVERSION COSTS OF TYPICAL SHIPPING BOARD STEAMERS

Average dwt.	5,300	7,650	8,650	9,520
No. available for conversion.....	112	7	136	63
Total dwt.	593,600	52,560	1,175,240	599,790
Total length of machinery spaces....	47' 3"	50' 0"	49' 6"	50' 0"
Average service shaft horsepower....	1,400	1,900	2,100	2,250
Average service speed, knots.....	10.5	10	10	10
Engineroom auxiliaries	14,500	19,000	21,000	23,000
Diesel generators and electrical equipment	39,500	50,000	53,000	55,000
Deck machinery	42,000	43,000	44,000	45,000
Main engine and maneuvering compr.	154,000	200,000	218,000	230,000
Removal, alterations and installation	60,000	70,000	80,000	85,000
Drydocking, scaling and painting....	6,000	7,000	8,000	10,000
Total cost of conversion.....	316,000	389,000	424,000	448,000
Approx. cost per s.h.p. of main engines	225	205	202	199
Approx. cost per dwt.....	60	51	49	47

The above figures are based on information informally furnished by manufacturers and ship repair plants for the conversion of a moderate number of vessels of each type so as to equitably distribute development costs and overheads. They cover a first-class installation throughout, with rugged and reliable engines and electrically driven engineroom and deck auxiliaries of the highest standard. They also include drydocking, scaling, and painting, but no hull repairs of an extraordinary nature. In each case due consideration was given to the major factors affecting the cost of conversion, such as size of shafting, available space and the amount of power that can be conveniently installed without expensive structural alterations.

Obviously, conversion costs could be materially reduced by retaining most of the present steam auxiliaries, supplementing them in such a way as will avoid the constant use of donkey boiler at sea, but such an arrangement would not reduce the port fuel consumption. Whether or not the economy attending a complete system of electric auxiliaries would be commensurate to its greater cost, would largely depend on trade requirements and the character and physical status of the present steam equipment.

If to the cost of conversion a purchase price of from 5 to 7 dollars per ton deadweight is added, the final cost per ton deadweight of completely reliable and economical motorships will vary from \$65 for the 5,300 deadweight ton vessels, to about \$53 for those of 9,500 tons deadweight.

These prices compare most favorably with \$35 per deadweight ton which includes approximately \$5 per deadweight ton for a complete overhauling for the best Shipping Board steam tonnage, which is from four to five years old as an average; and with the prevailing costs of from \$40 to \$45

TABLE XII.—SUMMARY OF COMPARATIVE PERFORMANCE—STEAMER AND MOTORSHIP

per deadweight ton for new foreign steam tonnage, depending on type, speed and trade requirements. They also favorably compare with the prevailing costs of foreign built motorships which vary from approximately \$70 to \$80 per deadweight ton. It should be noted, however, that these low prices are forced by the present depression and are accepted by shipyards in preference to closing down, and as they allow no profit to the builders they are likely to rise as the demand for new tonnage increases.

In addition to the advantages previously stated, it should be noted that for round voyages in excess of a vessel's total bunkering capacity an oil-burning steamship would be compelled to bunker the maximum capacity of her fuel tanks in order to purchase the minimum of costlier fuel abroad, thereby decreasing her cargo carrying capacity, or else purchase a greater amount abroad with correspondingly increased expenditure.

A coal-burning steamship, plying the longer routes, would necessarily bunker abroad for her return trip and will have to seek the ports where fuel is cheap, which sometimes entails long and costly detours, or else submit to the prices prevailing at the ports of call.

The converted vessel, however, can carry sufficient oil in her double bottoms to practically steam around the world, can seek the most advantageous routes regardless of her fuel requirements and is, therefore, possessed of great flexibility and potential earning power.

Neglecting, however, the additional revenue possible with the increased cargo-carrying capacity, the preceding tables show that the 8,560 deadweight ton converted vessel previously considered can be credited with a saving of approximately \$70,000 per annum, equivalent to a return of about 16.5 percent on the cost of conversion, whereas the major replacements of steam machinery already mentioned would yield returns varying from 12.5 to 5.5 percent. Therefore, the replacement of deficient turbines and watertube boilers does not appear as well justified as the conversion to Diesel propulsion.

Having thus far analyzed costs of conversion and savings in operation let us now investigate their ultimate effect when overheads and other fixed charges are taken into account. Taking for example the North Atlantic-River Plate route a previous table shows a saving of \$69,267 for the motorship over an oil-burner. Assuming equal cargoes carried, stevedoring and other operating charges not previously included would then be the same for both types and can be excluded from computation. For the purpose of this comparison the following fixed charges have been assumed for both types:

Depreciation	6	percent	per annum
Interest on purchase cost.....	6	percent	per annum
Profit on investment	10	percent	per annum
Federal taxes 12.5 percent of net revenue, or.....	1.25	percent	per annum
Insurance	4.75	percent	per annum
Total fixed charges.....	28	percent	per annum

Based on the above premises the following table was prepared to show the comparative effect of initial costs of steamers and motorships:

(a) Cost of steamer per dwt.....	30	35	40	45
(b) Investment for 8,560 dwt. steamer (a × 8,560).....	256,800	299,600	342,000	385,200
(c) Fixed charges, 28 percent of above (b ÷ 28 percent).....	71,904	83,889	95,872	107,856
(d) Excess operating expenses over motorship	69,267	69,267	69,267	69,267
(e) Total for steamer (c + d).....	141,171	153,186	165,139	117,123
(f) Equivalent investment for an 8,560 dwt. motorship (c ÷ 28 percent).....	504,200	547,000	590,000	632,600
(g) Equivalent cost per dwt. of motor- ship (f ÷ 8,560).....	59	64	69	74

The above shows that with a prevailing domestic market price for the best ready steam tonnage of approximately \$35 per deadweight ton the top price for a converted domestic motorship fully meeting the steamer's competition would be about \$64 per deadweight ton. And as previous estimates indicate that a Shipping Board steamer could be purchased and converted into an efficient motorship at an approximate

total cost of \$55 per deadweight ton it will be seen that a substantial differential is thus created that should materially assist the American flag converted vessel to not only meet the competition of new foreign steamers built at from \$40 to \$45 per deadweight ton but also of foreign motorships built at from \$70 to \$80 per deadweight ton.

But while Diesel hulls at a nominal price might induce well established shipowners to absorb some few vessels for conversion purposes, it is a well known fact that new companies are experiencing difficulty in obtaining the necessary financial assistance, the present high costs of domestic Diesel machinery acting as a further deterrent to a wider adoption of the motorship. Some reduction in production costs, however, are confidently anticipated as soon as a minimum of standardized sizes can be manufactured in adequate numbers, as American resourcefulness will then assert itself and excel as in other fields of mechanical endeavor.

Substantially all of the board's vessels thus far sold to private interests are carrying their owners' products or are being operated in protected trades, and from present indications it appears that there will be little further demand for such trades. Hence, it is logical to suppose that such new investment capital as is forthcoming will seek to absorb the board's ships operated in specific foreign services. Here, however, it will meet the formidable competition of an ever-increasing number of specially built foreign motorships and while reliable ready steam tonnage is obviously needed for maintaining these services, it is equally obvious that motorships need quickly follow, if the American owner, lacking the endless resources of the national treasury, is to survive.

CONVERSION OF CLASS "D" SHIPS SHOULD BE EXPEDITED

Therefore, the sooner low priced motorships are forthcoming the sooner will the investor's attention be engaged in the better available steamers to meet immediate demands and in the ships to be converted to meet later requirements. Every possible incentive should then be offered to expedite the efficient conversion of a large number of Class "D" steamers in order that the absorption of those in operation and in reserve may be expected to proceed in adequate ratio, otherwise those suitable for conversion would never, in their present condition, find buyers and would ultimately decay.

If, as we hope, our premises are correct, it is believed that the following measures should prove most beneficial:

- Modification of the construction Loan Fund, created under Section No. 11 of the Merchant Marine Act of 1920, so that its benefits will equally apply to the conversion of the best and most efficient type American Flag steamers into reliable and economical motorships.
- Adoption by the Shipping Board of a liberal policy that will permit competent and responsible American citizens to absorb the board's specific trade routes by the combined sale or charter of ready steam tonnage to meet immediate demands, and the purchase of hulls for Diesel conversion to meet later requirements.
- Direct conversion of an adequate number of Shipping Board steamers for the express purpose of fostering domestic Diesel development.

Measures (a) and (b) would undoubtedly render all meritorious conversion projects practically self-financing; their immediate usefulness, therefore, needs no comment.

Measure (c) logically implies the substitution of motorships for steamers on the least developed and remunerative routes. In this connection it should be noted that on October 1, 1923, thirty-six Shipping Board coal burning steamers, aggregating approximately 289,000 tons deadweight, were employed on various foreign services, some being long distance routes ideally suited for motorship operation. This measure would ultimately entail many far reaching advantages.

First. Would permit American Flag vessels to survive on the less desirable and remunerative routes, thereby making possible their eventual absorption by private interests.

Second. Would provide work for our languishing shipyards and preserve their organizations for future needs.

Third. Would develop and establish a domestic Diesel industry and eventually lead to lower production costs.

Private shipowners would then follow in the wake of the

resultant advantages, government vessels would be disposed at enhanced values, and, providing a constructive general policy is also adopted, the primary object of establishing an adequate and self-sustaining American merchant marine would be ultimately achieved.

Lighter and Cheaper Diesel Engines Must Be Developed

By J. F. Nichols

Chief Engineer, Newport News Shipbuilding and Dry Dock Company

THE part that motorships will play in the merchant marine will be determined by their success or failure to earn a greater profit in operation than steam vessels.

The advantages of the Diesel engine, especially its superior fuel economy, are well known and for some time this type of engine has been developed to the point where a number of makes are available which compare favorably with steam machinery in reliability of operation. A considerable number of installations have been made, many of which are giving satisfaction to their owners and operators. In general, however, these engines, particularly in the larger powers, are inherently so expensive for the power developed that under

the conditions at present prevailing in this country the charges due to the added first cost about counterbalance the saving in fuel so that the American owner frequently has not found it financially advantageous to build motor vessels.

What is needed is the development of a type of Diesel engine which shall be lighter and less bulky and expensive than the present accepted types. This problem is being attacked earnestly by numbers of experienced builders with excellent prospects for success and when we are able to build Diesel engines of proved reliability at costs which do not absorb their economy in fuel, we may look forward to rapid progress in the building of motorships.

The Probable Trend in the Adoption of Motorships

By W. W. Smith, Chief Engineer, Federal Shipbuilding Company

THE oil engine is in a state of development. The evolution is proceeding rapidly, and this process will probably continue for some time, judging from the history of the development of other prime movers such as the steam engine and steam turbine. It therefore seems best to consider two phases, viz., the immediate and the near futures. The following remarks are intended to apply to American vessels and conditions only.

While it is generally unsafe to forecast the future, the following opinion as to the probable trend is hazarded:

For the immediate future—a considerable amount of installations in small powers; a few of medium power, and practically none of high power; a number of conversion installations of medium power to Shipping Board vessels, and a very few in privately owned vessels.

For the near future—a large number of installations in small powers; a considerable number of medium power, and very few, if any, of high power.

The power referred to above is approximately as follows: Small, up to 1,000 shaft horsepower; medium, from 1,000 to 8,000 shaft horsepower; and high, from 8,000 shaft horsepower up.

The type of engine which will compete most successfully with the steam installation is important. The basic requirements for this are: (1) simplicity and reliability, (2) low weight, and (3) low cost.

Judging from a considerable number of estimates and comparisons, it appears that for an oil engine to compete successfully with the best steam installations of medium power, the following values for the main oil engine only can not be materially exceeded—(a) weight per shaft horsepower, 200 pounds; (b) cost per shaft horsepower, \$70.

It seems that the above requirements can be best met by the following:

(1) Simplicity and reliability. Elimination of complication of valves, valve gears, injection air compressors, tanks and piping.

(2 and 3) Small weight and cost. Providing for an impulse on the piston every stroke for medium power engines, and every other stroke for small power engines.

At present for small powers there is very little difference between two and four cycle engines with respect to weight and cost. However, it is possible that the two cycle engine may be developed further so as to give a lower weight and cost. Since there is little indication that this possibility will be realized in the near future, the two and four cycle types will be considered approximately equal.

If these basic requirements can be satisfactorily met by present or near future oil engines, the conclusion is that the best types to compete successfully are the single acting two or four cycle engine for small powers, and the double acting two cycle for medium powers.

Let us assume that reliable engines which meet the above requirements will be available in the near future. Then it would appear that the following applications of oil engines would be advantageous with respect to the net earnings of the vessel in average cases.

Class Number	Shaft Horsepower	Number of Screws	Type of Machinery*
1	Up to 1,000	1	Oil engine. S.A. — 2 C. or 4 C.
2	1,000—3,000	1	Oil engine. D.A. — 2 C.
3	3,000—5,000	2	Oil engine. D.A. — 2 C. or
		1	Steam turbine, Scotch boilers, superheated steam
4	5,000—up	2	Steam turbine, watertube boilers, superheated steam

*S.A. = single acting, D.A. = double acting, 2 C = two cycle, 4 C = four cycle.

There is of course a wide variation in the service conditions and requirements, and this will of course materially affect the selection of machinery for the specific cases. In general, the following considerations would govern the selection for the average case.

Small Powers.—Oil engine less complicated, and simpler to operate. Fuel consumption considerably less than half, and no stand-by fuel. Cost higher. Extra cost justified.

Medium Powers.—Oil engines slightly less complicated. Fuel consumption about half, and no stand-by fuel. Cost higher. Extra cost justified in most cases up to 3,000 shaft horsepower.

Large Powers.—Fuel consumption somewhat more than half. Flexibility and overload capacity less. Cost considerably higher. Extra cost not justified except in rare cases.

In general, the field for the oil engine in the near future will probably be in small and medium powers, and especially the former.

Twin Screws.—In small and medium powers the extra complication, weight and cost of twin screw installations does not pay and cannot be justified for ordinary vessels. The

basic principles in this respect are the same as for steam installations.

Diesel-Electric Installations.—Judging from many accurate estimates and comparisons, it is true beyond question that the complexity, weight and cost of Diesel-electric installations are far in excess of direct-drive. The fuel consumption is also greater. These disadvantages cannot be justified, and it is considered a mistake to use this system for ordinary vessels. For unusual conditions, and rare cases, there may be exceptions.

Motorships Reduce the Cost of Long Voyages

By A. B. Homer, Diesel Engineer, Bethlehem Shipbuilding Corporation, Ltd.

THE ultimate problem concerning us is to increase the net return on the investment required to place our merchant ships in operation, and to maintain this net return at such a figure that our merchant marine can successfully compete with those under foreign registry.

This may be accomplished in several ways; first, by reducing the investment charge; second, by reducing operating costs and, third, by increasing the amount of cargo carried per ship and hence the gross income.

Let us take up each one of the above and see of what assistance the motorship will be.

First, the cost of machinery is being kept high primarily because not enough motorships and Diesel engines have been built to permit a reduction in cost due to quantity and standardized manufacture. Operators and owners are, therefore, defeating their own ends by holding back new construction or conversion of existing ships. This applies equally well to the development and manufacture of auxiliaries, a very important item in motorship construction costs. Conversion of existing steamers to motorships, if properly carried out in quantity, and at low hull cost, should

give a reduction in the investment charge which could not be obtained otherwise.

Second, the fuel economy of the Diesel engine reduces operating costs. Here exists the greatest factor in its favor. This is particularly apparent when a motorship is operated over a long route, and, therefore, every effort should be made to operate motorships on long voyages and steamers on the short trips.

Third, the motorship will have an increased deadweight cargo capacity over a similar dimensioned steamer due to carrying less fuel oil for the same voyage distance.

It can, therefore, be readily appreciated from the above that the motorship has the inherent qualities to play a big part in the upbuilding of the American merchant marine. We need confidence, cooperation and action along constructive lines in building up our merchant marine and improving its efficiency as a competitive factor in the world's commerce.

To this end we have already been making efforts toward effecting a reduction in construction costs to reduce the investment charge, and thereby increase the net return on investment.

First Protect Our Merchant Marine, Then Develop the Motorship

By W. G. Groesbeck, Vice-President, New York Shipbuilding Corporation

MY opinion is that the Diesel engine has now been so far developed, both in the United States and abroad, that it can be regarded as a reliable type for marine purposes. With this in mind, the question remains whether, everything considered, the Diesel engine is the most available form of propulsion in a given case, having regard to first cost, upkeep, operating expense and the like. There is no general rule that can be laid down in these matters, and each case must be worked out on its merits. Personally, I believe that its field will be found in the long voyage trades. I am doubtful as to its expediency in short voyages.

Obviously what is true of American Diesel vessels is also true as regards foreign Diesel vessels; and in the world's commerce we will be confronted in motor vessels as in all other types with the differential against us due to higher building and operating costs. We cannot expect to compete with foreign flag vessels of any type unless this differential can in some way be made up.

The subsidy bill which failed last year was an effort in this direction; and was perhaps the most direct and sensible method of meeting the situation. What can now be advanced as a substitute I am at a loss to suggest. But it is obvious that we cannot compete directly, either in building or operating, with the low wages and scale of living that obtain abroad under our highly protected wages and corresponding living scale. It is true that in mass production we can sometimes do it, but ships are not built or operated in mass.

Therefore, since none of us would consider reducing our living scale and wages to meet conditions obtaining abroad, it follows that we must either protect our merchant marine as we protect everything else in this country, or abandon the idea of having one.

I have alluded above to a limited way in which the development of the motorship may be of assistance to our merchant marine. I had in mind the conversion of a certain number of the Emergency Fleet Corporation's cargo vessels to Diesel drive.

This again is a matter of dollars and cents. At present, with shipyards abroad taking work at any price to keep their organizations going, motorships can be had at very low prices; at less prices, probably, than such vessels are intrinsically worth. When the situation again becomes normal, it should be possible, if the hulls are sold low enough, to fit them out with Diesel drive and sell them at a fair profit, to the extent that there is a demand for this class of cargo carriers. The operating differential, however, would remain, as compared to foreign motor vessels.

I am very much in favor of doing this as quickly and as far as circumstances seem to allow. It would be a great misfortune, however, if in carrying out this program, we were to allow ourselves to cherish any illusions as to our having found a solution of the problems confronting our merchant marine. The real trouble and the cure I have, perhaps somewhat crudely, pointed out.

Competition in Overseas Shipping Must Be Met By Using More Efficient Ships and Propelling Machinery

By A. S. Hebble, Superintending Engineer, Southern Pacific Company, Atlantic Steamship Lines

IF we are to keep pace with our competitors in the ocean carrying trade of the world, we must meet them with efficient ships capably manned and well adapted to the trade conditions in which they are engaged. It requires but little study to see that this can only be accomplished by the construction of modern motorships on account of their low fuel consumption and long steaming radius in comparison with steam driven ships.

There are approximately two million tons of motorships in service and under construction. Having in mind that a very small portion of this is under the American flag, it is obvious that the motorship is finding great favor with our competitors and that unless we expect to see our flag disappearing from the seas we must resort to the most efficient type of both ship and propelling machinery.

Motorships are most advantageous on long voyages on account of their ability to carry a sufficient amount of fuel for a long return voyage. This enables the owner to buy his

fuel at cost where the most advantageous prices are obtainable. They also have an advantage in that they consume less fuel per day and consequently carry less weight of fuel for a given voyage which results in increasing the deadweight and thereby adding to the earnings by being able to carry more cargo.

It is to be regretted that the cost of motor propelling machinery is greater than steam propelling machinery. This results in increased depreciation, interest and insurance charges. This is a condition however that must be met by the Diesel engine manufacturer. The cost of Diesel engine construction could be materially reduced through standardization and by putting Diesel engine construction on a manufacturing instead of a building basis as is now the case.

Properly designed motorships, with reasonable care and when operated with suitable fuel and lubricating oils, are operating consistently and economically as is shown by numerous records now available.

Legislation Should Be Enacted Making the Shipping Board Loan Fund Available for the Conversion of Existing Tonnage into Motorships

By Lewis R. Ford, Manager, Diesel Engineering Department, Morse Dry Dock and Repair Company

THE present disturbed condition of international credit and exchange has not only reduced the volume of marine business and curtailed the profit possibilities in ship operation but has also accentuated the handicap imposed on American ship operators by the difference in cost in foreign countries and the United States of all items entering into operating expense.

It is only by the application of a high degree of professional skill and business acumen that the American shipowner, thus handicapped, can operate steamers in competition with foreign vessels of the same type, but the situation becomes most acute when these steamers must compete against the rapidly growing fleet of economical foreign motorships. The establishment of an American motorship fleet is the obvious way out of this situation, but the great difference between the construction cost of new hulls in the United States and in foreign countries seems to prohibit the production of new tonnage in this country. It is possible, however, to put high class motorship tonnage afloat at a very low cost per ton by utilizing the several hundred good Shipping Board hulls that are available for purchase at a nominal price. Careful investigation has definitely developed the fact that such hulls can be purchased, converted and put into service at a cost of \$40 to \$50 per deadweight ton, depending on the completeness of conversion.

Only a few such conversions are now being made because under present conditions, financing a conversion project of any magnitude is almost impossible. If ship bonds and mortgages could be distributed to investors throughout the whole country as readily as similar railroad securities, few banks would hesitate to lend financial assistance to the numerous firms and individuals who are eager to make Diesel conversions. Unfortunately the American investor does not take kindly to marine securities.

It seems then that the most practical step toward improv-

ing the efficiency of our merchant marine as a competitive factor in the world's commerce is to unlock the loan fund of the Shipping Board and make it available for Diesel conversion purposes. This loan fund was created by Congress about two years ago to encourage private interests to build new ships but during the two year period that the fund has been available, only two new Diesel ships have been built with its aid, and these were of a very special type to which the conversion method is not applicable.

Every person with the interest of the American merchant marine at heart should use every effort to demonstrate to our national legislators, individually and as a body, the wisdom of immediately passing an enabling act that will permit the Shipping Board to lend money out of its present loan fund for converting existing steamers to Diesel drive as well as for building new ships.

Steady Increase in Tonnage of Sea-going Motorships

THE world tonnage of full-powered ocean-going motor ships (2,000 gross tons and over) aggregated nearly 1,000,000 tons on June 30, 1923—an increase of about 4 percent over the total on June 30, 1922, according to a study by B. V. York of the Transportation Division of the Department of Commerce. Vessels of British, Danish, and American nationality show a slight decrease, compared with the 1922 figure. Germany has shown the most rapid increase in tonnage. The three Scandinavian countries, however, have almost equal amounts.

Motorships of 5,000 gross tons and over increased 10 percent, amounting to 664,735 gross tons—two-thirds of the total. Countries owning vessels of this class maintain almost the same relative position as under the 2,000 ton classification.

© Harris & Ewing

Herbert Hoover

Honorable Herbert Hoover, Secretary of
Commerce, will open the American Marine
Congress in New York on November 8.

Colonel E. A. Simmons
Chairman Central Committee

Walter M. McFarland
Chairman Administrative Committee

Great Congress to Feature Marine Week of 1923

Marine Congress, Conventions and Exposition to Play Important Part in Determining Future of American Merchant Marine

MARINE Week of 1923, from November 5 to 10, in New York city, will bring together the varied interests of the country which directly or indirectly depend upon shipping in the conduct of their affairs. The Marine Congress to be held at the Waldorf-Astoria during this week has as its primary object the co-ordination of these interests into a body through whose deliberations it is hoped will be found a basis upon which the American merchant marine can be operated in an economically satisfactory manner and in a way to increase the competitive capacity of American ships.

The Congress is being held on the invitation of the American Marine Association whose members are convinced that American shipping can best be served by the combined efforts of the representatives of the marine industry and of all allied industries directly or remotely interested in water transportation. The result is that practically every section of the United States is to be represented by delegates from 97 organizations including chambers of commerce, port authorities, farm organizations and representatives of the various industries engaged in manufacturing for export and the like.

The organization of this national movement has been in the hands of an administrative committee, and a central committee supported by twenty sub-committees which have been instrumental in developing the policies upon which the congress will function.

PURPOSE OF THE CONGRESS

No general policy has been decided upon by the committees, but they are asking the co-operation of all groups

and classes of people interested in shipping to assist in developing a program during the congress that will be generally satisfactory to all industries. With such a program, having the support of the various organizations participating, it is felt that the Administration and the United States Congress will be greatly influenced in establishing a concrete national shipping policy. Party politics and matters of a controversial nature, however, are to be barred from the Marine Congress.

A number of lines of activity have been decided upon which tend to show the trend of thought and effort that will be put into this movement. All of these divisions of activity are aggressive in the defense of American shipping.

As stated in the preliminary committee reports of the Congress, the object shall be:

To urge, sponsor and recommend the modification or repeal of statutory restrictions or laws which tend to burden the world-wide competitive capacity of American ships, but at the same time maintaining or establishing all necessary restrictions as pertain to the safety of passengers and crews, protection of goods and protection of rights, quarters and living standards of American crews.

To recommend the adoption of such new legislation as will increase the world-wide competitive capacity of American ships.

To recommend and urge such necessary modifications and changes in the steamship code as may be advantageous.

To develop and recommend such aid as will permit of an advantage in favor of building and repairing in American shipyards, with American labor and materials.

To recommend such standardization of construction and operation as will tend to reduce operating costs and increase competitive capacity.

To recommend and urge the repeal of such legislation as permits

Robert S. Alter
Chairman, Manufacturers' Committee

R. H. M. Robinson
Chairman, Steamship Owners and Operators Committee

H. H. Raymond
Chairman, Coastwise Shipping Committee

Edward B. Lyman
Chairman, Ports and Terminal Committee

A. A. Schantz
Chairman, Great Lakes Shipping Committee

R. D. Gatewood
Chairman, Standardization Committee

William H. Kelley
Chairman, Towing and Lighterage Committee

of government agencies (such as navy yards) competing with private enterprises (such as private shipyards).

To consider and make recommendations concerning government-owned ships or lines competing with private ownership.

To consider the advantage of reciprocal agreements with foreign lines on both outgoing and incoming shipments.

COMMITTEES OF ORGANIZATION

As noted above, the general plans for the development of the Congress have been in the hands of an administrative committee whose chairman is Walter M. McFarland, Babcock and Wilcox Company, New York, under the guidance of which the various sub-committees have been organized and put into operation as follows:

Central Committee, Edward A. Simmons, president American Marine Association, chairman.

Delaware River and Pennsylvania District Committee, Hon. J. Hampton Moore, Mayor of Philadelphia, honorary chairman.

Hampton Roads Committee, Capt. William H. Stayton, Baltimore Steamship Company, chairman.

South Atlantic States Committee, R. S. MacElwee, Commissioner Port of Charleston, S. C., chairman.

Mid-West and Mississippi River District Committee, Malcolm Stewart, Secretary Mid-West Farmers and Manufacturers' Conference, Cincinnati, chairman.

Great Lakes District Committee, Hon. Wm. E. Dever, Mayor of Chicago, honorary chairman.

Pacific Coast Committee, C. F. Gorman, traffic agent Port of Seattle, chairman.

Port of Greater New York, Hudson and State Waterways Committee, Charles H. Potter, president U. S. Ship Operators' Association, chairman.

Publicity Committee, W. A. Cather, Worthington Pump and Machinery Corporation, director.

Radio Committee, E. B. Mallory, Westinghouse Electric and Manufacturing Company, chairman.

Shipyards Committee, J. H. Mull, president Wm. Cramp & Sons Ship and Engine Building Company, Philadelphia, chairman.

Diesel Engine Committee, Rear Admiral Wm. S. Benson, Commissioner United States Shipping Board, Washington, D. C., chairman.

Manufacturers' Committee, Robert S. Alter, vice-president American Tool Works Company, Cincinnati, chairman.

Agricultural Committee, George M. Carey, Omaha Chamber of Commerce, chairman.

Steamship Owners and Operators' Committee, R. H. M. Robinson, United American Lines, chairman.

Coastwise Shipping Committee, H. H. Raymond, Clyde Steamship Company, New York, chairman.

Inland Waterways Committee, Hon. J. Hampton Moore, Mayor of Philadelphia, chairman.

Ports and Terminals Committee, Edw. B. Lyman, Passaic River Improvement Association, chairman.

Great Lakes Shipping Committee, A. A. Schantz, president Detroit and Cleveland Navigation Company, chairman.

Standardization Committee, Capt. R. D. Gatewood, United States Shipping Board, chairman.

Marine Insurance and Classification Committee, S. D. McComb, manager Marine Office of America, chairman.

Transportation Committee, Charles M. Muchnic, American Locomotive Sales Corporation, chairman.

Towing and Lighterage Committee, William H. Kelley, Flower Lighterage Company, chairman.

Banking Committee, Julian W. Potter, president The Coal & Iron National Bank, New York, chairman.

Exports Committee, Myron W. Robinson, president American Export Association, chairman.

Imports Committee, Frederic B. Shipley, Shipley-Hollis Company, chairman.

Entertainment Committee, Wm. Z. Gardner, president The Propeller Club of the Port of New York, chairman.

Exposition Committee, E. M. Roberts, Crane Packing Company, chairman.

Hotels Committee, Norris R. Sibley, McClave-Brooks Company, chairman.

Banquet and Entertainment Committee, H. W. Parsons, Powers Specialty Company, chairman.

Accommodations Committee, Chester M. Roe, New Jersey Asbestos Company, chairman.

The complete personnel of the Administrative Committee is as follows: Walter M. McFarland, chairman, Babcock and Wilcox Company; Frank J. Shipman, vice-chairman, The Texas Company; K. Warren Heinrich, secretary,

Winthrop L. Marvin
Vice-Chairman Central Committee

K. Warren Heinrich
Secretary Administrative Committee

Frank J. Shipman
Vice-Chairman, Administrative Committee

Jas. E. Plummer
Member, Administrative Committee

Hon. J. Hampton Moore
Honorary Chairman, Delaware River and Pennsylvania District Committee

W. P. Smith
District Chairman, Delaware River and Pennsylvania District Committee

William H. Stayton
Chairman, Hampton Roads Committee

R. S. MacElwee
Chairman, South Atlantic States Committee

Hon. William E. Dever
Honorary Chairman, Great Lakes District Committee

F. C. Bradbury
District Chairman, Great Lakes District Committee

Charles H. Potter
Chairman, Port of Greater New York, Hudson and State Waterways Committee

E. B. Mallory
Chairman, Radio Committee

Hon. Theodore Roosevelt
Member Radio Committee

Admiral W. E. Reynolds
Member Radio Committee

J. H. Mull
Chairman, Shipyards Committee

William S. Benson
Chairman, Diesel Engine Committee

American Marine Association; Charles F. Scott, General Electric Company; James Plummer, Newport News Shipbuilding and Dry Dock Company; Edward A. Colson, Babcock and Wilcox Company; Frank W. Sterling, The Sterling-Cooper Corporation; W. A. Cather, Worthington Pump and Machinery Corporation.

The complete personnel of the Central Committee is as follows: Edward A. Simmons, chairman, president American Marine Association; Winthrop L. Marvin, vice-chairman, vice-president American Steamship Owners' Association; K. Warren Heinrich, secretary American Marine Association; Hon. Herbert Hoover, Secretary of Commerce; Alfred Gilbert Smith, president American Steamship Owners' Association; Charles H. Potter, president U. S. Ship Operators' Association; John Dowd, vice-president Maritime Association of the Port of New York; Frederick A. Russell, president New York Tow Boat Exchange; H. A. Magoun, president Atlantic Coast Shipbuilders' Association; Homer Ferguson, president Council of American Shipbuilders; Capt. C. A. McAllister, Society of Naval Architects and Marine Engineers and vice-president American Bureau of Shipping; Capt. John F. Milliken, secretary Neptune Association; William Livingstone, president Lake Carriers' Association; Matthew Hale, president South Atlantic States Association; Myron W. Robinson, president American Manufacturers' Export Association; John E. Edgerton, National Association of Manufacturers; O. E. Bradfute, president American Farm Bureau Federation; E. E. Spafford, State Commander, American Legion.

The personnel of the various committees includes many prominent men from all sections of the country; for example, there are the mayors of six cities on the Delaware District Committee; the mayors of four cities on the Great Lakes District Committee; Admiral Benson is chairman of the Diesel Engine Committee; J. H. Mull, president of William Cramp and Sons Ship and Engine Building Company, is chairman of the Shipyards' Committee.

The Congress itself will convene on Thursday morning, November 8, and will hold morning and afternoon sessions on that day and Friday, November 9. All the sessions of the Congress will be open to any individuals interested in the matters being discussed.

The Honorable Herbert Hoover, Secretary of Commerce, will preside at the opening session of the Congress on Thursday morning, November 8, and the following sessions will be presided over by prominent individuals representing the major groups taking part.

EXTENSIVE RADIO PROGRAM PLANNED

Coincident with the calling of the Congress it is planned to have sixteen or eighteen of the principal high power broadcasting stations distributed over the country take part in a general program prepared and directed by the radio committee.

To disseminate the thoughts and opinions of the leaders in various industries, associations and other institutions composing the Congress, radio will be used for the first time in an organized nation-wide program.

E. B. Mallory, chairman of the radio section of the Associated Manufacturers of Electrical Supplies, one of the seventy-eight national organizations participating in and endorsing the Congress is chairman of the radio committee of the Congress. To insure the successful and broad dissemination of an adequate knowledge of the needs of the nation, prominent Government and industrial executives are contributing their support and effort toward the success of the plan by serving as members of the radio committee. The membership of this committee includes:

Hon. Herbert Hoover, Secretary of Commerce.
General Pershing, U. S. A.
Theodore Roosevelt, Assistant Secretary of the Navy.
Admiral Benson, United States Shipping Board.

Rear Admiral Reynolds, United States Coast Guard.
A. H. Griswold, vice-president, American Telephone and Telegraph Company.

Major General Harbord, president, Radio Corporation of America.

H. P. Davis, vice-president, Westinghouse Electric and Manufacturing Company.

J. G. Barry, vice-president, General Electric Company.

Powell Crosley, Jr., president, Precision Equipment Company.

Eugene McDonald, president, Chicago Radio Laboratory.

and others of prominence.

The chairman has appointed subcommittees of the general committee in charge of programs, broadcasting stations and publicity, and sectional committees in each broadcasting center to have immediate charge of the activities at those points, and plans are rapidly being formed to use radio for the first time as a means of disseminating knowledge to the entire nation.

MARINE CONVENTIONS DURING THE WEEK

The nation-wide interest created in the Marine Congress will undoubtedly bring every man of importance in the shipbuilding and operating industries to New York during Marine Week and will add materially to the attendance of the annual meetings of various marine societies which will be held during the week.

The principal meeting will of course be that of the Society of Naval Architects and Marine Engineers, which will be the thirty-first general meeting of the Society. This year the meetings will be held in the Engineering Societies building, 29 West 39th street, on Thursday and Friday, November 8 and 9. Professional sessions will begin at 10 A. M. each day.

The program of the meetings was published on page 590 of our October issue.

During the week the American Steamship Owners' Association, the United States Ship Operators' Association and the Atlantic Coast Shipbuilders' Association will also hold meetings.

MARINE EXPOSITION

It is expected that the interest created in the Marine Congress will greatly influence the success of the Marine Exposition which will be held November 5 to 10 at the Grand Central Palace under the auspices of the American Marine Association. The exposition will be open daily from 12:30 noon to 10:30 P. M. Various special attractions will be provided daily and the delegates to the Congress will find the exhibits of both general and educational interest. The two previous annual expositions held by the association showed an excellent attendance of those individuals connected with the marine industry. This year, with the greatly increased gathering of interests both directly and indirectly depending on shipping, the exposition, featuring as it does every phase of transportation by water, will be a greater success than ever.

INSPECTION TRIPS

Through the courtesy of the steamship owners and operators and the United States Government arrangements have been made to show the delegates to the Congress as much as possible of ships and shipping while they are in New York.

The United States Navy Department has ordered the U. S. S. *Colorado*, the latest super-dreadnought of the Navy, to New York to be open for inspection during this week. Numerous of the larger passenger vessels of our merchant marine will also be open for inspection as well as the piers and terminals about the port. Visiting delegates will be given an opportunity to inspect all types of merchant vessels, including cargo vessels, oil tankers and passenger ships. Included in this group of merchant vessels, will be the flag-

Who's Who At the Exposition—

A Directory of Exhibiting Companies, Their Representatives, Products and Where to Find Them

Ajax Rope Company, Inc., 149 Broadway, New York.—Representatives: R. S. O. Lawson, M. L. Chapman, Chester Woodnorth, John White, Milton Mintzer, Russell Robb, Benjamin C. Hill, Norman Rounds. Booth 44.

Akimoff Propeller Company, Harrison Building, Philadelphia, Pa.—Diagrams, photographs and models of propellers, all built upon the "circulation" theory. Representatives: N. W. Akimoff, Dr. S. E. Slocum. Booth 67-B.

American Brass Company, Waterbury, Conn.—General copper and brass products for marine work; Admiralty condenser tubes; tobin bronze rods and shafting. Representative: L. B. Comstock. Booth 90.

American Car & Foundry Company, 165 Broadway, New York.—Berwick electric metal heaters. Representatives: F. C. Cheston, W. M. Earl, D. B. Wallace. Part of Booth 85.

American Steel Foundries, Chicago, Ill.—Booth 52.

Asbestolith Manufacturing Company, 1 Madison avenue, New York.—Samples of flooring. Representatives: R. C. Burnside, Miss B. V. Ross. Booth 97.

Ashton Valve Company, 161-179 First street, Cambridge 41, Boston, Mass.—Main boiler pop safety valves; smaller pop safety valves and relief valves; pressure and vacuum gages, gage and boiler testing outfits and large size marine whistles. Representatives: C. W. Buckelew, C. W. Ulrick, C. D. Moth-eral. Part of Booths 18 and 19.

Babcock & Wilcox Company, 85 Liberty street, New York.—Full size sectional model of Babcock & Wilcox 4-inch tube boiler; various boiler valves and fittings; sections of boiler headers; a working exhibit of the concentration salinity indicator; full size model of various Babcock & Wilcox design oil burners, among which will be the latest type oil burner, namely, the "Mayflower"; new boiler water testing outfit which will include a test for alkalinity. Representatives: C. W. Middleton, J. H. King, George H. Daniels, John Coleman, A. Ross Mackay, James Graham, Edw. A. Colson. Booths 76 and 77.

Beaver Tile, Inc., 442 West 42nd street, New York.—Beaver cork composition tile, a deck covering for all passenger accommodations and a new deck covering for steel decks to be used as a basis for other materials; Linomosaics, a new craft in decorative wall panels. Representative: A. N. Newell. Booth 11.

Bethlehem Shipbuilding Corporation, Ltd., Bethlehem, Pa.—Standard line of Bethlehem-Dahl oil burners with assembled unit of heaters and pumps; burner will be shown in operation using light oil and water; several Bethlehem-Weir pumps, including a turbo feed pump and a reciprocating pump in operation; also a new direction indicator developed by the Union Iron Works plant of the company in connection with engine room telegraphs. Representatives: A. W. Christian, G. A. Richardson, G. E. Laurence, G. W. Grove and F. K. Steinrock. Booth 68.

Briggs Engineering Works, 227 24th street, Brooklyn, N. Y.—"Burwell" fuel oil pumping and heating set, air register, oil burner, duplex strainers. Representatives: W. E. Yandell, C. N. Wheeler, H. M. Kuppinger, H. B. Patterson. Booth 104.

Brown Instrument Company, 50 Church street, New York.—Pyrometers, indicating and recording; recording thermometers and pressure gages; draft gages; resistance thermometers; automatic temperature control and automatic signaling equipment; salinity meters for boiler feeds and evaporator measurements; electric CO₂ recorders; electric tachometers—indicating and recording. Representatives: G. W. Keller, A. E. Keeler, J. D. Andrews, E. Schneider, C. L. Simon, M. M. Watkins. Booth 65-B.

Brunswick-Kroeschell Company, New Brunswick, N. J.—Brunswick marine type direct-connected ammonia compressor. Representatives: William O. Whitney, William Carpenter. Booth 93.

Burmeister & Wain, 27 Whitehall street, New York.—Representatives: S. M. Petersen, R. L. Larsen, H. C. Hallings. Booth 86.

The Coen Company, 50 Church street, New York.—Complete oil burning system piped up to show the different component parts ready for operation; new design "ELR" swing type air register firing front and burner set; also steel construction easy cleanable fuel oil heater; latest design type "A" burner with its self-seating holder; fuel oil strainers, also strainers especially adapted to Diesel engine work. Representatives: W. M. Wampler, G. H. Ord, H. B. Chamberlain, F. S. Harper, F. Hall. Booth 79.

J. A. Coffey Engineering Corporation, 1650 Broadway, New York.—Sample floor, miniature carfloat and photographs for exhibition. Representatives: Miss Adele Eckstein, C. H. Alexander, J. A. Coffey. Booth 12.

William Cramp and Sons Ship and Engine Building Company, Philadelphia, Pa.—Diesel engine, marine steam turbine, reduction gear, bronze castings. Representatives: W. P. Smith, C. D. Cramp, C. R. Peterson, J. C. Shaw. Booths 70 and 71.

Crane Company, 836 South Michigan avenue, Chicago, Ill.—Complete line of steel material for all pressures, 150 pounds working pressure to 3,000 pounds working pressure inclusive; complete line of steel material showing representative line of marine valves and fittings. Representatives: F. C. Bradbury, G. E. Barker. Booth 66.

Crane Packing Company, 53 Park place, New York.—A model condenser on which a continuous test will be made; entire line of packings for general marine work. Representatives: J. N. Walton, E. M. Roberts, C. W. Bryden. Booth 227.

The De Laval Separator Company, 165 Broadway, New York.—Three sizes of De Laval oil purifiers, Nos. 200, 300, 600, assembled complete; three purifier bowls, showing results of the process. Representatives: P. F. Miller, D. F. Miller, Allan Hopper, H. H. George, E. V. Mayhill, M. A. Monroe. Part of Booth 85.

Diamond Power Specialty Corporation, Detroit, Mich.—Diamond model B rear end soot blower for Scotch marine boilers, model BBM rear end front operated blower for Scotch marine boilers, model G 2 M revolving soot blower for marine watertube boilers, Valve-in-Head soot blowers for marine watertube boilers, model G 2 soot blowers for watertube boilers. Representatives: L. W. Nones, Robert June. Booth 74.

Diehl Manufacturing Company, Elizabeth, N. J.—Ventilation blowers, motor driven; desk fans, ceiling fans, exhaust fans and motors for general shipboard use. Representatives: M. W. Buchanan, W. E. Fey, J. R. Marvin, J. G. Levy. Booth 31.

O. M. Edwards Company, Inc., Syracuse, N. Y.—Marine sash or glass balancing device. Representatives: J. J. Edwards, A. J. Horgan. Booth 15.

Electric Storage Battery Company, Philadelphia, Pa.—Wireless battery for service on shipboard; radio batteries—both A and B—such as would be used for the reception of broadcast entertainments in homes or aboard private yachts; a gigantic submarine cell; a "shadow-box" showing an oil painting of an industrial scene, calling attention to the manner in which Exide-Ironclad batteries are serving the shipping industry; batteries used for ignition and yacht lighting are also shown. Representatives: E. F. Kullberg, A. C. Ferdon, R. E. Kearney, J. W. Weight, J. Carey, M. T. Ford, J. L. Fuller. Booth 31.

Electro Sun Company, Inc., 161 Washington street, New York.—Phases of blue and black printing and photo-printing that will interest marine men; display of Lefax system. Representative: A. L. Weil. Booth 253.

Falk Corporation, Milwaukee, Wis.—Flexible couplings;

Main Floor of Marine Exposition, Grand Central Palace, Lexington Avenue and 46th Street, New York City

small double reduction gear unit; moving pictures of geared oil engines and photographs of marine gear installations. Representatives: M. P. Fillingham, W. O. Beyer. Booth 87.

L. W. Ferdinand Company, 152 Kneeland street, Boston, Mass.—Jeffery's marine glue; Linoleum and tile cements; Century products. Representatives: August Schlueter, L. W. Ferdinand and L. C. Herring. Booth 228.

Fire Detecting Wire Corporation, 2 West 45th street, New York.—Four standard control panels in operation complete with fire stations, gongs, etc. Representatives: W. H. Garrison, C. Van Zandt, S. C. Zabriskie. Booth 335-336.

Foster Marine Boiler Corporation, 111 Broadway, New York.—Complete detail parts of Foster marine superheaters and a section of the new Foster marine economizer. Representatives: H. W. Parsons, R. L. Lovell, J. J. Nelis. Booth 101.

General Carbonic Company, 542 Fifth avenue, New York.—Cylinders containing CO₂ gas so connected with fire-detector as to demonstrate the effectiveness of carbonic gas as a fire extinguisher aboard vessels. This method is known throughout marine circles as the Lux System. Representatives: A. McKinny, H. R. Minor, C. W. Wardell. Booth 49.

General Electric Company, Schenectady, N. Y.—Ten kilowatt steam engine driven generating set with a portion of the steam chest and cylinder removed, and glass doors for the column to show the operation of the reciprocating parts; also a switchboard for this unit which will be in operation; two 18-inch searchlights, one hand control, the other electrically controlled, will be in operation; one COM type direct-current motor for use in connection with deck auxiliaries direct-connected to a shoe type solenoid brake for use with deck machinery, the motor to be operated and controlled through a C-410-A type master controller with suitable resistance; in addition, a separate motor bearing head will be sectionalized to show the method of lubricating the journal, and the manner in which entering water is prevented from passing into the oil wells by suitably designed passages and

chambers; automatic motor driven air compressor as used for cleaning electrical and other apparatus, for an emergency compressor on motorships, and for pneumatic tools used in drilling holes, beading and calking seams, scaling plates, etc.; RCM direct-current motor in operation; 32-volt 500-watt turbine-generator set designed especially to supply electric energy for the lighting of a headlight or searchlight on tugs or other vessels; the principles of Diesel engine electric drive as applied to the propulsion of various types of vessels will be shown in animated form in a manner that the non-technical visitor will readily understand the principles involved; 174-A drum type watertight controller; various charts giving interesting data on 322 ships equipped with marine geared turbines and 39 vessels having General Electric Company electric propulsion and control machinery. Representatives: L. W. Shugg and engineers of the Marine Department. Booths 3, 4, 5, 6.

B. F. Goodrich Rubber Company, Akron, Ohio.—Cutless bearings; sealing rings; mechanical rubber goods for the marine industry. Representatives: C. F. Sherwood, L. Q. Moffitt, W. A. Whitenack. Half of Booth 84.

Griscom-Russell Company, 90 West Street, New York.—Representative examples of line of marine auxiliaries; Reilly submerged type evaporator, feed water heater assembled with complete fittings in both single and two-pass types, feed water filter and grease extractor of the pressure type and fuel oil heaters both of the Reilly coil design and the more recent straight tube type; sectional model of multiwhirl oil cooler which has been used so extensively for the cooling of lubricating oil for geared turbines, turbo electric and Diesel engine installations; marine fittings such as automatic float controls, special valves, separators, etc.; new G-R low pressure expansion joint. Representatives: R. Colston, B. P. Collings. Booth 60.

Hill Rotors, Inc., 42 Broadway, New York.—Air compressors, liquid pumps, vacuum pumps, combined liquid and vacuum pumps. Representatives: Myron F. Hill, Francis A. Hill, Walter G. Thomson, T. H. Wolf. Booth 252.

Mezzanine Floor of Marine Exposition, Grand Central Palace, Lexington Avenue and 46th Street, New York City

Hooven-Owens-Rentschler Company, Hamilton, Ohio.—Views of the plant and Hamilton engines and parts of Hamilton equipment. Representatives: Henrik Greger, H. A. Smith, F. L. Hummer. Booth 17.

Ingersoll-Rand Company, 11 Broadway, New York.—Photographs of semi-Diesel engine installations on board ship as well as of marine oil engines, machinery and other equipment for shipyard uses. Literature will also be distributed descriptive of various products of the company. Representatives: L. D. Albin, F. W. O'Neil, D. C. Keefe, R. W. Douglass, R. R. Womack, L. V. Armstrong, G. W. Morrison, F. K. Armstrong, J. W. Morton, P. T. Brostrom, J. V. Mossman, H. R. Fee, H. G. Erb. Booth 47.

Journal of Commerce and Commercial Bulletin, 32 Broadway, New York.—Representative: H. V. S. Negus. Booth 50.

Walter Kidde & Company, 90 West Street, New York.—Rich system for smoke detection; Lux system for fire extinguishing; electro-vapour radiator for electric heating. Representatives: W. H. Freygang, A. M. Doxsey, G. Crosby Hiss. Booth 49.

Knudsen Motor Corporation, 30 Church Street, New York.—120 horsepower 2 cycle engine, full Diesel type; 50 horsepower 2 cycle engine, full Diesel type. Representatives: M. Knudsen, J. B. Tait, C. Knutson, J. R. Pitbladdo, Capt. P. P. Songdahl, F. G. Schneeberg, Jr., J. W. Barnett, A. Doll, G. Allardyce. Booth 81.

Lunkenheimer Company, Cincinnati, Ohio.—Complete and interesting display of both high and low pressure valves, boiler mountings, whistles and similar high grade engineering appliances; steel, bronze and iron globe angle, check and gate valves; water columns, water gages, gage cocks, blow-off valves, safety non-return stop valves, etc. Representative: W. Reynolds. Booth 95.

McIntosh & Seymour Corporation, Auburn, N. Y.—Photographic enlargement of largest engine, type 6-C-56. Representative: B. P. Flint. Booth 59.

Marine Decking & Supply Company, 116 North Delaware

avenue, Philadelphia, Pa.—Madesco tackle blocks; American Lit-O-Sil-O decking; American Lit-O-Sil-O flooring; several paintings showing American Lit-O-Sil-O. Representatives: G. W. Selby, W. L. Peebles, E. P. Jewell. Booth 110.

Marine Engineering and Shipping Age, 30 Church Street, New York.—MARINE ENGINEERING AND SHIPPING AGE, *The Boiler Maker*, "Shipbuilding Cyclopaedia," "Practical Marine Engineering," "Laying Out for Boiler Makers" and marine books. Representatives: Colonel E. A. Simmons, Henry Lee, C. R. Mills, R. V. Wright, George Slate, James Swan, H. H. Brown, L. S. Blodgett, W. Z. Gardner, H. B. Bolander, J. A. Miller, B. L. Dombrowski, R. F. Duysters, N. C. B. Fowles, J. E. Anderson, H. E. McCandless, R. W. Zinn, George Laxar, E. H. Allen, G. W. Stutt. Booths 94 and 106.

The Marine News, 26 Water Street, New York.—Booth 83.

The Marine Review, Cleveland, O.—Booth 30.

Morse Dry Dock & Repair Company, foot of 56th Street, Brooklyn, N. Y.—Photographs of plant and pictures covering not only the general run of straight ship repair work, but including important Diesel repair and oil burning installations as well. A unique working demonstration of the Morse fuel oil burning system will be in operation as well as a working model of certain new devices. Representatives: Frank Breyfogle, D. J. Irish, L. R. Ford, D. V. Stratton. Booth 72.

National Malleable Castings Company, Cleveland, O.—Complete line of anchor chain together with anchor and connecting shackles as well as swivels. Representatives: Benjamin Nields, Jr., W. C. Lewis, E. Sihler, E. E. Eyman, R. E. Valentine. Booth 57.

National Meter Company, 299 Broadway, New York.—Full line of oil and gasoline meters for marine purposes with special reference to meters for oil-burning equipment. Representatives: G. D. MacVeagh, J. J. Pirrung. Booth 14.

Natural Carbonic Gas Company, Newark, N. J.—Carbonic gas in steel cylinders. Representatives: P. E. Fay, T. P. Arnold. Booth 267.

New London Ship & Engine Company, Groton, Conn.—One 180-horsepower engine. Booth 75.

Newport News Shipbuilding & Dry Dock Company, Newport News, Va.—Representatives: L. D. Pickering, F. L. Hoffman, R. H. Lee. Booth 32.

Northern Fire Apparatus Company, Minneapolis, Minn.—Electric driven fuel oil pump (high pressure), electric driven fuel oil pump (high vacuum) in operation; boiler feed pump; fire and bilge pump. Representative: J. A. Hense. Booth 54.

Pantasote Company, 11 Broadway, New York.—Vehisote panel and tile boards for bulkheads, ceilings, wainscoting, partitions, etc.; Pantasote upholstery and curtain materials; Russaloid upholstery. Representative: W. A. Lake. Booth 28.

Peabody Engineering Corporation, 110 East 42nd Street, New York.—Double-ported hinged type register fitted with Peabody-Fisher wide range mechanical burners; the double-ported type of register was especially designed for high capacity on low drafts. Representatives: J. P. Leask, E. B. Sadtler, S. T. Warner, R. C. Vroom. Booth 13.

Port of Charleston, Charleston, S. C.—Booth 255.

Power Specialty Company, 111 Broadway, New York.—Complete detail parts of Foster marine superheaters and a section of the new Foster marine economizer. Representatives: H. W. Parsons, R. L. Lovell, J. J. Nelis. Booth 101.

Pneumercator Company, 40 Flatbush Avenue Extension, Brooklyn, N. Y.—Pneumercator tank gages, ship's draft gages and distant boiler gage glass. Representatives: W. Thomas, Calvin J. Wicks. Booth 36.

Radio Corporation of America, New York.—Booth 48.

The Roto Company, Hartford, Conn.—Roto tube cleaners for boilers, both watertube and Scotch marine; condensers, both surface and double-pipe; evaporators, heaters, etc., together with Paragon header scrapers and cap cleaning machines. Representatives: Messrs. Doherty, Van Nortwick and Kelley. Booth 266.

Row & Davis Engineers, Inc., 90 West Street, New York.—RanD system for reliquidizing fuel oil without the aid of steam coils in ships' inner-bottom tanks; improved Paracoil fuel oil heater; standard Paracoil feed water heater; Paracoil evaporator, fresh water still; R & D steam trap, grease extractor. Representatives: Messrs. Row, Davis and Thompson; also Messrs. Smith and Young. Booth 63.

Rubber-All-Products Company, 821 Broadway, New York.—Rubber-All waterproof suit; the exhibit will include, "The Acid Test," which will show by actual demonstration the indestructible waterproof material used in the manufacture of Rubber-All suits. Representative: H. S. Dube. Booth 69.

Scovill Manufacturing Company, Waterbury, Conn.—Cup drawn Admiralty condenser tubing. Samples of corroded tubing, defective tubing and the best grade of material shown under the microscope. Samples of brass mill products, such as sheet, rod, wire and seamless tubing as well as manufactured articles made from raw materials. Representatives: E. H. Callanan, P. Davidson, C. A. Gleason, C. B. Kerr, Jr., G. T. Power, L. R. Root, M. N. Rose, C. W. Snowman, A. M. Southall, M. L. Sperry, Jr., W. E. Twining, L. L. Williams. Booth 58.

Sperry Gyroscope Company, Manhattan Bridge Plaza, Brooklyn, N. Y.—Navigational instruments; two complete MK VI Gyro compass equipments—a Gyro-pilot, the automatic helmsman, 5 of which during the last two years have efficiently steered five ships over 150,000 miles; improved helm angle indicator system, improved ship's log system; improved revolution indicator system. Sperry 18-inch high intensity Duralumin marine searchlight; 36-inch high intensity searchlight similar to the one installed on the *Leviathan* and as installed on the 5 Night Air Mail Fields. Gyroship's stabilizer model in operation. Representatives: R. B. Lea, Messrs. Whitaker, Jobson, Sparling, Patterson, Bates and Hodgman. Booths, 20, 21, 22, 23.

Shipley Construction and Supply Company, 42nd Street and 2nd Avenue, Brooklyn, N. Y.—Refrigerating machinery and parts. Representatives: R. G. Land, E. Phillips. Booth 35.

The Sterling-Cooper Corporation, 318 West 39th Street, New York.—Technical and commercial marine books; Sterling's Marine Catalog. Representatives: F. W. Sterling, T. G. Newbery. Booth 67-A.

B. F. Sturtevant Company, Hyde Park, Boston, Mass.—Stationary type vacuum cleaner; portable vacuum cleaner; individual oil burner turbine blower; vertical single engine; gasoline engine-driven generating set; turbine for auxiliary drive; various size ventilation fans both motor and turbine driven; 3,000-foot ventilation heater. Representatives: E. B. Williams, E. L. Moran, W. A. Finnegan. Booth 107.

Submarine Signal Company, 160 State Street, Boston 9, Mass.—Submarine bell; submarine oscillator; standard submarine signal receiving apparatus; new portable submarine

direction finder; new submarine sounder; stereomograph pictures showing activities of the company in making navigation safe. Representatives: H. J. W. Fay, E. P. Howe, E. F. Irwin. Booth 256.

Sun Shipbuilding Company, Chester, Pa.—Large size model oil tanker *Atlantic Sun*; photographs of ships built and various views of shipyard and shops; photographs of Diesel engines built at yard. Representative: T. T. Borden. Booth 78.

The Superheater Company, 17 East 42nd Street, New York.—Model of the Elesco fretube superheater as applied to the Scotch marine type boiler; model of the Elesco superheater as applied to marine watertube boiler and boilers used on Mississippi river boats; steam pyrometers for measuring temperatures; engineering data and literature. Representatives: H. B. Oatley, G. E. Ryder, C. A. Brandt, G. E. Kershaw, W. McLintock, G. L. Moore, J. A. Barnes. Booth 73.

The Texas Company, 17 Battery Place, New York.—Miniature oil derrick and full line of marine lubricants. Representatives: F. J. Shipman, H. W. Schilling, E. A. Lobb, A. St. James, G. C. Bartlum, J. L. Ward. Booth 35.

P. S. Thorsen & Company, Inc., 81 Coffey Street, Brooklyn, N. Y.—Complete line of insulation, including practical demonstrations of the saving to be made by proper insulation. Representatives: P. S. Thorsen, M. L. Bullard, R. S. Warner, W. Davies, T. Drydale, V. Menig. Booth 98.

W. & J. Tiebout Company, 118 Chambers Street, New York.—Standard line of ship joiner hardware with various new patterns and designs that have been brought out recently. Representatives: J. Tiebout, Jr., G. V. Carlin, Chas. H. Schult, F. J. Morrissey, J. D. Gillespie. Booth 27.

Todd Shipyards Corporation, 25 Broadway, New York.—Todd twin pole arc welder; Todd oil burning galley range; Todd fuel oil burners for marine and land installation. Mr. Arnold L. Wernert, instructor for the "TODD" Oil Burner School, will be present during the entire period of the show and will give an outline of the course of instruction in oil burning. Representatives: Robert G. Payne, A. J. Holifield, J. A. H. Hood. Booths 92 and 108.

United States Department of Commerce, Washington, D. C.—Booths 214 to 225, inclusive, and 230 to 240, inclusive.

United States Department of Public Health, Division of Marine Hospitals, Washington, D. C.—Booths 316 to 323, inclusive.

United States Navy, Washington, D. C.—Booths 201 to 213, inclusive, and 241 to 251, inclusive.

Valentine & Company, 456 Fourth Avenue, New York.—Table top testing table; running water machine; Valspar varnish stains; demonstration of Valspar's waterproof qualities; panels of clear Valspar, Valspar varnish stains and Valspar enamels; color chart made up of glasses showing different shades of Valspar enamel; original painting by Lieut.-Com. Henry Reuterdaahl, U. S. N. R., used in advertising the fact that Valspar was used on the *Leviathan*. Representatives: H. Pulsifer, D. Walker, deCamp Freeman. Booth 43.

Welin Davit and Boat Corporation, 305 Vernon avenue, Long Island City, N. Y.—Models of various types of Welin quadrant davits with lifeboats attached; samples of Permacote red lead. Representatives: H. F. Sailor, Walter J. Krolman, O. J. Slaght, Chas. White, R. E. Keppler. Booth 254.

Westinghouse Electric & Manufacturing Company, 165 Broadway, New York.—100 kilowatt turbine driven auxiliary power generating set; 1½ kilowatt turbine generator lighting unit; sectional bake oven; marine oscillating fan; inter-cooler type air ejector; Diesel engine generator model; pilot house control desk; marine controllers; marine motors; electric water heaters; engine circulating water pump. Representatives: G. H. Froebel, W. B. Barrett, C. C. MacMillan, R. E. Aldridge, W. E. Thau, H. C. Coleman, E. D. King, H. M. Southgate, B. H. Hamilton, C. F. Duffield, J. J. Brown, W. F. James, E. F. Clark, L. D. Howell, H. L. McCarter, P. A. Sensenig. Booths 82 and 83.

C. H. Wheeler Manufacturing Company, Lehigh and Sedgley Avenues, Philadelphia, Pa.—New type of Radojet air pump, designed for closed feed water systems; two small surface condensers combined in one unit arranged one between the first and second stage and one after the second stage; marine type condensate pumps; dynamometer; Radojet augments. Representatives: G. L. Kothny, C. Lang, J. J. Mullan, J. Dobson. Booth 7.

Worthington Pump & Machinery Corporation, 115 Broadway, New York.—Pumps; meters; 120 horsepower Diesel engine. Representatives: L. Katsenstein, W. A. Cather, I. W. Jackman, C. B. Humphrey, J. J. Morch. Booth 96.

New and Interesting—

Marine Devices Described Below Will be Shown at
the Marine Exposition This Year for the First Time

Vacuum Cleaner and Turbo Blower Developed by Sturtevant

TWO new pieces of equipment will be featured at the B. F. Sturtevant Company, Hyde Park, Boston, Mass., exhibit—the Type-E vacuum cleaner and the A-13 individual oil burner turbine blower. The Type-E cleaner is known as the horizontal type and is of the same general design as the larger size cleaners made by the company.

The vertical chamber is a dust collector. The fans which create the suction are in the horizontal section at the center. The air first passes through the collector and is thoroughly filtered before being exhausted. The dirt, therefore, cannot reach the fans or bearings and clogging or unbalancing of

Horizontal Vacuum Cleaner Known as Type-E

the fans or injury to them is thus avoided. The bearings of the fan are automatically lubricated and arranged so that no grease can reach the dust bag. The dust bag is easily removable for cleaning or renewal.

This type of cleaner is made in seven sizes besides various other types of vertical and portable machines.

TURBO BLOWER

The A-13 turbo blower unit consists of a multi-velocity impulse steam turbine and a fan of the cast aluminum propeller type. The turbine bucket wheel is a solid forging with buckets milled into the rim. Because of the hollow shaft, the ball bearings are exceptionally large thereby assuring long life. Each gland is fitted with carbon packing which requires no lubrication or adjustment during its life. Convenient arrangements are made on the turbine casings for attachment of the oil burning apparatus.

Size A-13 Blower Unit

The unit is fitted with a specially designed and patented governor of the speed limiting type which does not allow the turbine to exceed its safe operating speed at any pressure.

Double Ported Register Fitted with Wide Range Burner

AMONG the special equipment which the Peabody Engineering Corporation, New York city, will exhibit this year is a double-ported hinged type register fitted with Peabody-Fisher wide-range mechanical burners.

This register was especially designed to meet the needs of ships operating under natural draft with fairly low stacks.

Wide Range Mechanical Burner Assembled with Double Ported Horizontal Type Register

This register is an adaptation of the standard Peabody air register and has an enlarged furnace opening and an auxiliary air port in place of the standard back plate.

The amount of opening of the auxiliary port is controlled by means of a ring which is supported on three rollers. This ring opens and closes with a helical movement so that all chance of the ring sticking or becoming cocked is eliminated. The rotative movement of the ring is controlled by a crank actuated by a handle on the register front. The design shown in the accompanying illustration is for natural draft operation and is hinged so as to permit ready access to the furnace. This type of register has been in service on ship-board for some time and has given exceptional results.

This same type register is used in conjunction with the Howden heated air system and supplants the combination coal and oil front. The Hudson River Day Line steamer *DeWitt Clinton* is fitted with a complete installation of these registers, which have been used with great success during the season just passed.

For use with forced draft double front installation, the design is modified slightly, the hinges being fastened to the front plate, permitting the register to swing out of the double front. This design will be installed on the Day Line steamer *Alexander Hamilton* now being built.

New Principle Discovered in Pump and Compressor Rotor Design

WHAT is claimed to be a hitherto unknown principle of rotary motion as applied to pumps and compressors will be the main feature of the exhibit of Hill Rotors, Inc., New York city. It is claimed that the new Hill Rotors mechanical motion can handle pressures from 20 to 400 pounds at any speed up to 2,000 revolutions per minute with a satisfactory degree of efficiency. These rotors consist of

Hill Rotors Motor Compressor Unit

one inside the other; one has nine lobes or teeth and the other eight. The curves of these rotor lobes involve entirely new geometrical relations and open up an entirely unexplored mathematical field. They are such that they have a continuous pressure holding engagement between the high pressure port and the low pressure port.

The outer rotor drives the inner rotor and air or liquid in one of the spaces never slips back between the lobes into the next larger space behind it. Each space does its own compression and discharges independently of its neighbor. These rotors rotate on fixed centers, the inner rotor being eccentric to the outer so that they open a series of spaces on

one side to receive the pumped fluid and close them to discharge it on the other side.

Due to the pressure holding engagement between the rotors and the positive mechanical action, pressure and volumetric efficiency are practically independent of the speed of rotation. The only factor to vary with the speed is the capacity.

On test a small paint spraying air compressor had a volumetric efficiency of over 90 percent at 50 pounds pressure. A small liquid pump had between 95 percent and 100 percent

Form of Rotors Developed for Pump and Compressor Service

volumetric efficiency on pressures up to 100 pounds. These pumps have attained pressures up to 370 pounds on air and 400 pounds on liquids. In both cases when attaining these pressures the power was shut off to save the piping.

Due to the fact that there is practically no clearance between the rotors, Hill rotors, it is claimed, will pull as perfect a vacuum as can be measured on a mercury column.

Where power efficiency is not of prime importance one Hill rotor pump can be made to handle liquids, air compression, or a vacuum.

In electric units there are only three moving parts, the inner rotor, the outer rotor, and the driving shaft which is direct connected to the motor.

Salinity Concentration Indicator—Oil Burner with Self-Contained Forced Draft

TWO new developments in apparatus made by the Babcock & Wilcox Company, New York, which will be shown at the Exposition this year, are a concentration salinity indicator and a mechanical atomizing oil burner known as the Mayflower design with a self-contained forced draft system.

The salinity indicator shows automatically and instantaneously an increase in the density of the water by showing various colored lights, a white light for 0.5 grain, a green light for 0.5 to 5 grains and a red light for a density over 5 grains. This is an especially valuable feature in connection with the evaporator room, as an instantaneous warning is given when the quality of the distillate changes, thus obviating the possibility of running poor water.

The signal light controller also keeps an accurate check on

Mayflower Design Oil Burner Which Eliminates All Ducts for Forced Draft Service

the condenser, which is an important feature for merchant vessels. A continuous indication of the quality of the condensate is shown at all times, the warning lights showing as in the case of the evaporator, but with a slightly different range. The white light shows a density up to 0.3 grain, the green light shows from 0.3 up to 1 grain, and the red light shows above 1 grain.

MAYFLOWER DESIGN BURNER

The Mayflower design burner consists of the main casting with a bladed cone, to which a hollow shaft turbo blower is attached. The atomizer fits through the blower shaft and may be moved in and out by the adjustment of coupling studs. A quick detachable yoke and coupling, similar to that used on other Babcock & Wilcox types of burners is also fitted to the atomizer. An impeller blade is fastened to the bladed cone by means of lugs. Access may be gained to the furnace by swinging aside the burner which is hinged. This also provides for the insertion of a fire tile plug which is put in place when the burner is not in use. Steam connections to the turbine are detachable and somewhat similar to the quick detachable yoke and coupling used on the oil burner connection.

The special advantages claimed for the burner are that on forced draft work it eliminates all ducts as well as the large blowers supplying air to the ducts; further, any number of burners can be run independently without having air leakage through dead burners, as is sometimes found when double front construction is used. As the air for combustion can be regulated very closely to the required amount, owing to the multiplicity of speeds available with the turbo blower, higher efficiency can be obtained.

Radojet Air Pump for Closed Feed Water Systems

THE latest development of the C. H. Wheeler Manufacturing Company of Philadelphia is a new type Radojet marine air pump designed for closed feed water systems.

Two small surface condensers combined in one unit are arranged, one between the first and second stage, and one after the second stage. The first one is called the inter-

condenser and the second the after-condenser. The first condenses the steam discharged from the first stage, while the second one condenses that from the second stage. The condensate from the main condenser is used as circulating water for both condensers. With this arrangement the condensate does not come in contact with the air discharged by

Radojet Air Pump for Marine Service

the Radojet. All the heat contained in the steam is returned to the boilers which results in a thermal efficiency of about 98 percent.

In each of the two condensers provision is made for a cold water pass, which is supplied from the main circulating pump. This water supply is used only when starting up the main turbine unit, when there is not sufficient condensate

impinging against the bearing wall, is thrust into the groove when the flow of water carries it away. Again, the resiliency of the tough rubber construction of the cutless bearing nullifies in large part vibration of the screw.

Self-Contained Oil Pumping Outfit

THE combined pump and heater set shown in the accompanying illustration is a development to meet the needs for a self-contained unit for fuel oil burning. It forms part of the Bethlehem (Dahl) mechanical oil burning system which is manufactured at the Moore Plant, Elizabeth, N. J., of the Bethlehem Shipbuilding Corporation, Limited.

This self-contained unit consists of the fuel oil pressure

Bethlehem Oil Pumping Unit

pumps, heaters, suction and discharge strainers, with the necessary connecting piping, gages, etc., all mounted on a welded steel base. These units are manufactured in all sizes to meet any requirements in oil burning installations.

This set is being shown for the first time to the marine industry at the Marine Exposition.

Unusual Electric Radiator

WALTER KIDDE AND COMPANY, New York City, engineers handling the Rich system for detecting and extinguishing fires, will show a novel electric radiator at the Marine Exposition this year. Each electro-vapour radiator is in effect an individual steam heating plant consisting of an ordinary cast iron radiator with a chamber permanently attached containing a small quantity of liquid which vaporized by a contained electric heating element. The liquid will last indefinitely, but the quantity should be inspected each season.

The radiator operates under a vacuum, affording relatively

quick heating. The electro-vapour radiator gives, by the turn of a switch, the same ideal heat electrically as the usual steam or hot water radiator.

Electro-vapour radiators are furnished in any size and may be fitted to operate at different heats and voltages. The

Electro Vapor Wall Radiator of the Stateroom Type

heating surface required is calculated in accordance with the usual practice for steam radiation. An approximation is 7 square feet of heating surface for each 20 degree increase in temperature in a room 10 by 12 by 8 feet having one window.

Submarine Direction Finding and Submarine Sounding Apparatus for Small Boats

THE portable submarine direction finder and submarine sounder are devices which the Submarine Signal Corporation, Boston, Mass., has developed after years of experimentation. These devices are designed to afford a much needed protection to those adrift in small boats and will be shown for the first time at the Marine Exposition. The great value of a direction finding device which makes it possible to inform the user of the direction from which sounds are coming and thus enables him to steer his boat or vessel toward the source of sound has been generally recognized. This company has consequently designed portable sending and receiving apparatus wherewith this desired result can be attained.

The submarine direction finder is virtually a large inverted Y. The finder is provided with a collar, surrounding the vertical portion, to which is attached a rod which is used to support it from the side of the vessel. This rod is pinned to the collar, thus forming a hinge which allows the device to move freely backward and forward. A plate is also provided which is designed to be bolted permanently to the rail of the vessel from which the submarine direction finder is to be used. This arrangement is equivalent to gimbals and thus, while permitting the direction finder to be rotated on its vertical axis, at the same time allows the force of gravity to hold the tube always in a vertical position.

When the submarine direction finder is to be used the rod is inserted in the hole in the plate and a pin inserted to keep the rod and finder in position. This arrangement permits the submarine direction finder to be readily mounted when observations are to be made and removed when the observations have been concluded.

The finder has two rubber bulbs, one on the end of each arm. Two small tubes, one from each bulb, run from the bulbs to the end of the vertical pipe and project as shown in Fig. 1. These bulbs are the underwater ears. Two flexible rubber tubes, known as stethoscope binaurals connect the ends of the small tubes of the direction finder with the ears of the listener. In this way the observer can hear the submarine sounds; he will hear the sound waves striking the left

and can be heard at very considerable distances. Moreover they are of a character that enables the submarine direction finder to be used with the greatest ease and accuracy.

Mechanical Oil Burner with Self-Seating Holder

THIS year the Coen Company, oil burning specialists of San Francisco, will show the new type-A mechanical oil burner with self-seating holder as a feature of their exhibit.

The Coen burner is a flexible mechanical oil burner. By

Section Through Coen Type-A Burner Fitted with Holder of Self-Seating Design

hand bulb in his left ear and those striking the right hand bulb in his right ear.

When an observer is listening to sound in air he can turn his head until he knows apparently instinctively that he is facing the source of sound. This same principle is utilized in the submarine direction finder.

The submarine direction finder is provided with a handle at the top of the vertical piece and, as the vertical piece turns freely in its support, the bulbs can be rotated with the vertical

flexible is meant a burner that can produce a full fire or a small fire at the will of the fireman and change from one fire to the other instantly without extinguishing the flame, altering the oil pressure, or impairing the quality of the flame.

This control is made possible by the adjustable burner tip. The complete burner consists of a special inner valve, a short piece of tubing, a tip, a cap to hold the tip in place and a steel rod running through the burner to provide means for regulating the discharge from the tip. The Coen burner will operate with fuel oil of any gravity.

The regulating rod in the burner has a rotative movement of $\frac{1}{4}$ inch only. When turned to the extreme left the burner is wide open delivering the maximum fire. By turning the rod to the right the fire is gradually diminished until the stop pin comes in contact with the shoulder of the burner tip at which point the minimum or standby fire is produced. It is not possible to turn the rod far enough to extinguish the fire for the burner valve is for regulating only and not a shut-off valve. The sectional view shown is a burner with the type-A self-seating burner socket.

Great Congress to Feature Marine Week

ship of the American merchant marine, the *Leviathan*, the *Minnewaska* of the Atlantic Transport Lines, the *Seekonk*, one of the latest type American motorships reconditioned by the William Cramp & Sons Ship and Engine Building Company, the *Cleveland* of the United American Lines and the *Westphalia* of the Hamburg-American Line.

BANQUETS TO BE HELD

The American Marine Congress will hold a banquet under the auspices of the American Marine Association on Thursday evening, November 8 at 7:30 P. M. in the grand ball room of the Waldorf-Astoria hotel. Secretary of Com-

Fig. 1.—Portable Submarine Direction Finder Fig. 2.—Submarine Sounder for Lifeboats

piece as an axis until the sound seems to reach the observer from a point directly in front of him. When this is the case the handle is pointing directly toward the source of sound.

DETAILS OF SUBMARINE SOUNDER

The submarine sounder is shown in Fig. 2. It consists of a metal cup to one side of which is attached a rod. The submarine sounder when in service is hung from the rail of the boat in such a way that the open side of the cup is facing downward and the rod extends upward and somewhat above the rail of the boat. The user is provided with a hammer and the submarine signals are produced by hitting the end of the rod with the hammer.

The signals created in this way are sharp and clear

merce Herbert Hoover; O. E. Bradfute, president of the American Farm Bureau Federation; Winthrop L. Marvin, vice-president of the American Steamship Owners' Association; Admiral Plunkett, United States Navy, and Captain Irving O'Hay, famous adventurer upon whose life was based Richard Harding Davis' "Soldiers of Fortune," will be among the principal speakers of the evening. Secretary of the Navy Denby has directed the 80-piece band of the U. S. Battleship *Colorado* to be in attendance to furnish a concert during the evening.

The annual banquet of the Society of Naval Architects and Marine Engineers will also be held in the grand ball room of the Waldorf-Astoria on Friday evening, November 9.

The New Shipping Board Plan

By Harold F. Lane

WASHINGTON, D. C.

THE Shipping Board has worked out a plan for the operation of the Government-owned ships, as a substitute for the previous managing operator plan, which seems to amount practically to direct Government operation, at least for the present, while avoiding the legal obstacles which Attorney General Daugherty found to stand in the way of the board's plan for operation through subsidiary corporations. Under the plan as announced by the board on October 16 to be put into effect in the immediate future in the North Atlantic, United Kingdom and Ireland service by the consolidation of five routes into one line, the physical operation of the ships will be under the direct supervision of the board, while the soliciting and booking of freight, the handling of the freight at the terminals and its loading on board ship will be in the hands of loading agents, under contract with the board and paid for on a strictly commission basis. In other words, the plan is one of subsidiary organizations but not subsidiary corporations, as the Attorney General held that to turn the ships over to separate corporations would amount to a sale of the vessels not in accordance with the provisions of the law.

Under the existing plan the managing operators operate the ships for the Government and receive a commission on the business done as well as a husbanding fee, while the Government receives the revenues and pays the expenses. It is the announced intention of the board to utilize as far as possible the experience and services of the present operators as loading agents, but according to the board's announcement, "the monies appropriated by Congress will be expended under the direction of the board and under the immediate supervision of Government officials." Complete details of the plan, which is expected to be applied to other services, have not yet been made public, nor has the exact nature of the contract to be entered into with the loading agents been disclosed, although it is stated that the contracts will provide for such modification as experience shows to be desirable and can be terminated at the board's discretion upon reasonable notice. At the White House it was stated that the President had not approved any specific plan but expected to confer further with Chairman Farley before anything was done of a permanent nature.

According to the statement issued by Chairman Farley announcing the plan, the board considered that it "had worked out a solution of the problem of operating its ships so as to utilize as far as practicable the recommendations received from those familiar with the present day shipping problems." He added that "it is expected by this arrangement that the hearty co-operation and best endeavors of experienced private shipping organizations will be obtained and utilized to the fullest extent in conducting the Government's shipping operations."

The board hopes that considerable savings will result from the consolidation of routes, and this action means, Mr. Farley said, that "the American Government intends to remain squarely behind the maintenance of these American flag routes. The changes determined upon are intended to give better, more efficient and more elastic service between this country's North Atlantic ports and those on the east and west coasts of the United Kingdom."

NEW ORGANIZATION FOR U. S. LINES

The board has also announced a reorganization of the management of the United States Lines which, it was stated, "makes of the United States Lines practically a subsidiary corporation of the Emergency Fleet Corporation."

The supervision of the United States Lines has been placed under a sub-committee of the Shipping Board consisting of Commissioner O'Connor, as chairman, and Commissioners Plummer and Benson.

The relations of this sub-committee to the affairs of the United States Lines will be essentially those of a committee of a board of directors to whom the board has delegated immediate supervision. W. J. Love is to be managing director. He has resigned as general manager of the Fleet Corporation. T. H. Rossbottom will be appointed general manager in charge of operations.

"The new arrangement makes of the United States Lines practically a subsidiary corporation of the Emergency Fleet Corporation," Mr. Farley said. "The operating department of the United States Lines will have immediate supervision of the physical operation, maintenance and care of the ships, victualing and purchasing departments, and all other activities pertaining to the operation of the vessels of the line. There will be a freight traffic manager and a passenger traffic manager also. The treasurer of the Fleet Corporation is to be treasurer of the United States Lines. The general comptroller of the Fleet Corporation will have charge of the accounting. This change in the operation of the United States Lines is to be immediately effective."

American Legion Pledges Aid for Upbuilding of Merchant Marine

AT the fifth annual convention of the American Legion held last month in San Francisco the following resolution, proposed by Edward Elwell Spafford, commander of the Department of New York, was adopted:

"If all navies were sunk by treaty, merchant marines would then be the principal source of naval power. On this basis Great Britain would at present have as much power as all of the larger nations combined. While it is unlikely that nations will agree to a complete elimination of navies, we recommend that all practicable steps be taken to build up the American merchant marine to a size commensurate with the size of the Navy and proportionate to the size and wealth of this country.

"As the merchant marine will be called on in time of war to support the Navy, there should be close co-operation in time of peace between the departments of the Navy and the merchant marine. In order to aid our merchant marine, as well as to economize on naval expenses and to train regular Navy personnel on combatant ships, we recommend that auxiliary vessels required for naval purposes in time of peace be chartered from well-established merchant lines.

"We desire to see at least 50 percent of the trade of this country carried in American-built ships flying the American flag and manned by American officers and men all of whom shall live like Americans. To this end we again solemnly pledge our best efforts."

Savannah Liner City of Chattanooga
Showing the Steel Cargo Booms*

New Savannah Liner City of Chattanooga

New Savannah Liner Added to Atlantic Coastwise Fleet

The City of Chattanooga, First of Two Sister Ships Built at Newport News for the Ocean Steamship Company, Goes Into Service

THE accompanying photographs and plans give a good idea of the S. S. *City of Chattanooga*, the latest addition to the Ocean Steamship Company's fleet. This fine vessel was placed in the New York-Savannah service early in October and will be followed this month by her sister ship, the *City of Birmingham*.

Built by the Newport News Shipbuilding and Dry Dock Company, Newport News, Va., to the highest class of the American Bureau of Shipping, the *City of Chattanooga* may be taken as the "last word" in American coastwise vessels. While the general arrangement is similar to that of the *City of St. Louis* and *City of Montgomery* it will be noted that an additional deck, the boat deck, has been fitted as well as other additions, both in structure and equipment.

The general dimensions and particulars of the ship are as follows:

Length overall	401 feet
Length between perpendiculars	382 feet
Beam, molded	52 feet
Depth, molded, to hurricane deck.....	35 feet
Depth of double bottom.....	3 feet 6 inches
Load draft	18 feet 6 inches
Load displacement	7,180 tons
Approximate deadweight at 18-foot 6-inch draft	3,500 tons

Wireless Room

Cargo capacity	323,596 cubic feet
Bunker capacity	457 tons
Tonnage, gross	5,861
Tonnage, net	4,343

The hull is constructed of steel with six watertight bulkheads, inner bottom from fore to after peak bulkheads and four plated decks—the orlop, lower, main and hurricane. The shell is plated with in-and-out strakes, the frames being joggled over the landing edges. The decks, in cargo spaces, are supported by girders and wide-spaced stanchions.

The entire hurricane and promenade decks are given over to passenger accommodation, provision being made for 164 first and 40 second class passengers.

There are 72 first class staterooms equipped with berths, the upper berths being of the Pullman type. Each of these rooms is provided with a 12-inch electric fan, hot and cold running water

and a steel thermos bottle for drinking water.

In addition to the berth rooms, there are ten suites, each of which is equipped with twin beds, bureau, wardrobe and private bath.

There are also eight private bathrooms, so arranged in conjunction with the ordinary staterooms that they may be placed at the disposal of occupants of connecting rooms, thus

107-133	Inner bottom, No. 5 S.....	22,894	87.45	89.94
133-154	Inner bottom, No. 6 P.....	7,213	27.55	
133-154	Inner bottom, No. 6 S.....	7,213	27.55	
163-A.P.	After peak	29,542	112.84	
Total		278,241	782.54	272.46
76-79	Fresh water tank on C. L.....	5,092		18.91
76-79	Fresh water tank on port.....	2,504		9.29
76-79	Fresh water tank on stb'd.....	2,504		9.29
92-94	Service tanks	400	1.53	1.48
Grand total		288,737	784.07	311.43

NOTE—7.48 gallons = 1 cubic foot, 35 cubic feet salt water = 1 ton, 36 cubic feet fresh water = 1 ton.

Coal Bunker

Between Frames	Space	Net Cubic Feet	Tons
73-97	Port., stb'd and C. L.....	19,219	457.62

Ash bunker, 201 cubic feet, 4.79 tons.
NOTE—Capacity of coal bunker is figured to shell, internals deducted.
42 cubic feet = 1 ton coal.

Equipment

Two 7,665-pound stockless bower anchors.
One, 2,765-pound stockless stream anchor.
270 fathoms 2½-inch stud link chain cable.
90 fathoms 4½-inch circumference steel wire stream line.
120 fathoms 5-inch circumference steel wire tow line.
Two 90-fathom, 8-inch circumference manila hawsers.
Two 90-fathom, 7-inch circumference manila warps.

Scantlings

FRAMES: Spaced 24 inches in peaks, 27 inches elsewhere.
Frames outside double bottom, 6-inch by 3.5-inch by 18-pound channels, from peak to peak, extending to main and hurricane decks alternately aft of frame No. 41; with every frame carried up to hurricane deck forward.
Frames in peaks, 6-inch by 3½-inch by 11.7-pound angles with reverse bars.
Frames inside double bottom, 3½-inch by 3-inch by 9.1-pound angles throughout on solid plate floors; 6-inch by 3.5-inch by 3.5-inch by 15.3-pound channels on open floors.
REVERSE FRAMES: On frames in peaks, 3½-inch by 3-inch by 7.9-pound angles in fore peak to hurricane deck on every frame, in after peak to main deck on every frame.
Inside double bottom, on solid plate floors, 3-inch by 3-inch by 8.3-pound angles in holds to 3½-inch by 3-inch by 9.1-pound angles in machinery space. Double under main engine and boiler bearers. Six-inch by 3.5-inch by 3.5-inch by 15.3-pound channels throughout on open floors.
FLOORS: Inside double bottom solid plate floors forward of three-fifths length amidships, in engine and boiler rooms and under outer ends of watertight bulkhead stiffener brackets. Solid floors on every third frame elsewhere with intermediate open floors.
Solid floor plates and brackets on open floors .35-inch in holds, .40-inch in engine space, .46-inch in boiler space.
Floors in peaks, .35-inch; watertight, .38-inch; tank end floors .38-inch.
LONGITUDINALS INSIDE DOUBLE BOTTOM: .34-inch in holds; .40-inch in engine space; .46-inch in boiler space.
DOUBLE BOTTOM PLATING: Center strake and margin .48-inch for ¼ length amidships; .625-inch in machinery space; .40-inch at ends. Margin, 31 inches minimum width, exclusive of flange; center strake, 47 inches wide; other strakes, .40-inch ½ length and ends; .625-inch engine space; .625-inch boiler space.
Riveting: Center strake and margin, treble riveted butt laps, ¾-inch rivets for ½ length amidships; treble riveted butt laps, ¾-inch rivets M. S.; double riveted butt laps, ¾-inch rivets at ends. Other strakes, double riveted butt laps, ¾-inch rivets in machinery space to double riveted butt laps, ¾-inch rivets.
STEM: 8¾ inches by 2½ inches.
STERN FRAME: Rudder post, 8 inches by 7½ inches.
PROPELLER POST: 9¾ inches by 7½ inches below boss, 8 inches by 7½ inches above.
RUDDER STOCK: 10 inches diameter.

forming suites for the accommodation of two, four or six people.

Public baths are located on both hurricane and promenade decks, in addition to the private baths before mentioned, and all baths, private and public, are supplied with hot and cold salt and fresh water, and have a shower over each tub.

The public rooms are unusually commodious and are tastefully finished and decorated.

The dining saloon extends the full width of the ship, seats being provided for all passengers at one sitting. The pantry and galley are particularly well arranged for giving prompt service without encroaching upon the entrance passageways, and the grouping of mess rooms, galley stores and refrigerators is such as to give efficient service with the minimum personnel.

The music room is located directly over the dining saloon with a center well opening into the latter. It is supplied with a piano and phonograph and has abundant seating capacity tastefully arranged.

The smoking room is located on the boat deck, an innovation in the Ocean Steamship Company's vessels, made to meet the wishes of those who use the room as well as those who do not.

The joiner trim throughout the first class quarters is of natural mahogany combined with white and gold. The main stairways are paneled in mahogany and have ornamental iron balustrades. The smoking room is finished in fumed oak paneling and has an ornamental glass dome.

With the exception of the music room, which is carpeted,

all floors of staterooms, passages and public rooms are covered with "Everlastic," cork or rubber tile.

An automatic fire alarm system is fitted in all staterooms, public rooms and cargo holds.

The provisions for handling and stowing cargo reflect the advance in this department of ship construction. Among these may be noted the increase in height of cargo ports, to ensure the safe and expeditious handling of automobiles.

PROPELLING MACHINERY

The propelling machinery consists of a triple expansion, surface condensing engine having cylinders 23 inches, 43 inches and 72 inches in diameter and 48 inches stroke, designed to develop 2,900 indicated horsepower at 75 revolutions per minute and 200 pounds per square inch working pressure. With this power the ship is capable of a speed of over 12½ knots at normal load draft. The valve gear is of the Stevenson link type with direct acting steam reversing gear. An Edwards air pump, 26 inches in diameter by 21 inches stroke and two bilge pumps, 5 inches diameter by 21 inches stroke, are driven off the main engine. All other pumps are independent.

The crank shaft is 14¾ inches in diameter; thrust, 14¾ inches; line, 13¼ inches and tail shaft 14¾ inches with continuous brass liner.

The propeller is of built-up type, 16 feet in diameter, with cast iron hub and four bronze blades.

The main condenser is circular with cast iron body and approximately 4,100 square feet of cooling surface.

S. S. City of Chattanooga: Plan of Machinery Space

The following auxiliaries are installed:

Centrifugal circulating pump, 14-inch suction and discharge driven by single engine 8 inches diameter by 10 inches stroke.

Auxiliary condenser, 450 square feet cooling surface.

Steam pumps, built by the Warren Steam Pump Company:

2 main and auxiliary feed, single vertical, 14 inches by 24 inches.

2 fire and bilge, duplex vertical, 12 inches by 8 1/2 inches by 12 inches.

1 ballast, duplex vertical, 7 1/2 inches by 8 1/2 inches by 12 inches.

1 sanitary, duplex vertical, 12 inches by 8 1/2 inches by 12 inches.

2 fresh water, duplex vertical, 6 inches by 6 inches by 6 inches.

1 drinking water, duplex horizontal, 3 inches by 2 inches by 3 inches.

1 auxiliary air and circulating combined, 8 inches by 10 inches by 10 inches by 12 inches.

1 ammonia condenser, circulating, duplex horizontal, 4 1/2 inches by 3 3/4 inches by 4 inches.

There is a Reilly multi-coil feed water heater, a combined feed and filter tank of approximately 70 cubic feet capacity and two 2 1/2-inch Metropolitan injectors.

The boilers are four in number, of single end Scotch type, 14 feet 9 inches diameter and 11 feet 6 inches long, over heads; constructed for a working pressure of 200 pounds per square inch. Each boiler has three 46-inch Morison furnaces, connected to separate combustion chambers. The furnaces are fitted to burn coal under natural draft.

The engineers' work shop is provided with a 9-inch engine lathe, drill press and grinder, all motor driven.

The electric plant consists of two 35-kilowatt General

Electric generating sets and, in addition, a 10-kilowatt emergency set with gasoline engine by the Matthews Engineering Company. In all there are approximately six hundred 40-watt lamps installed on the vessel, including twelve cargo clusters, and an 18-inch searchlight.

Two Brunswick-Kroeschell 4-ton refrigerating machines are installed for cooling ship's provisions and drinking water.

In general, the *City of Chattanooga* is completely outfitted and equipped as becomes a first class passenger and cargo steamer, and is a notable addition to the coastwise fleet.

Two Important Repair Jobs

THE S. S. *Hoven*, a fine steel tank steamer of approximately 10,000 tons deadweight capacity which was built by the Bethlehem Shipbuilding Corporation, Ltd., at Sparrow's Point, Md., in 1919, struck a submerged rock off San Benito Island on August 29 with the results shown in the illustration.

Such was the force of the blow that practically the entire structure in way of the forepeak, from the 16-foot waterline down, and extending aft for a distance of over 30 feet was destroyed, both the forepeak bulkhead and the forward end of the centerline bulkhead being included in the damaged area. Had the ship been an ordinary cargo steamer, she

would probably have foundered, but because of the extensive subdivision characteristic of tank steamers, she remained afloat and we understand made port under her own steam.

As indicating the extent of the repairs made necessary by the accident, the following particulars are of interest:

- New stem bar from 18-foot waterline to forefoot.
- 29 shell plates removed and replaced by new.
- 4 shell plates removed and faired.
- 11 transverse floor plates with accompanying intercostals, clips, etc., removed and replaced by new.
- 2 web transverses partially renewed.
- 18 longitudinals partially renewed and faired.
- 3 lower strakes of forepeak bulkhead renewed.
- 2 lower strakes of centerline bulkhead renewed at forward end.
- 16 breasthooks renewed or faired.

The repairs are being carried out by the Los Angeles Shipbuilding Company at a price of approximately \$64,000. It

Damage to Bow of S. S. West Arrow Above Waterline

Crumpled Bow of Tank Steamer Hooven

should be noted that this figure covers some bottom damage not shown by the illustration.

Of quite different origin, but of very nearly as serious a character is the damage shown by the two illustrations of the S. S. *West Arrow*. This vessel, a Shipping Board cargo steamer of 8,567 tons deadweight built by Skinner and Eddy, Seattle, Wash., in 1918, was run into by the British S. S. *Haverford* while on a voyage from European ports to Boston. The *Haverford*, a steamer of 11,635 gross tons, was moving at a good rate of speed and apparently struck the *West Arrow* very nearly end on. Thanks to the good material and workmanship of the latter vessel, the structural damage was practically confined to the forepeak, although the ship received a thorough shaking up and the propelling machinery was somewhat disarranged, but not sufficiently to prevent the ship from steaming into Boston, where she was dry docked.

The following is an outline of the repairs made necessary by the collision:

Damage to Bow of S. S. West Arrow Below Waterline

- 36 shell plates removed and replaced by new.
- 8 shell plates removed and faired.

New stem bar and forefoot casting, complete.
 10 frames and reverse frames renewed from keel to fore-castle deck.
 1 hawse pipe casting renewed.
 7 fore-castle deck beams renewed.
 15 main deck beams renewed.
 Chain locker renewed.
 Forepeak tank top and bulkhead, extensive renewals and fairing.
 Turbine and gear casing raised for inspection.

Line shaft couplings to be broken and bearings opened up and adjusted.

The contract for this work has been awarded to the Robins Dry Dock & Repair Company, Brooklyn, N. Y., for \$47,970, the time allowed for completing the work being 38 days. In addition to the repairs, this figure covers cleaning the ship's bottom, painting two coats, and ordinary voyage repairs.

British Shipowners Face Keen Competition Abroad

Rapid Growth of New North German Lloyd Fleet — Proposals Advanced for Equalizing Operating Costs—Advantages of the Motorship

By W. H. Wendon

THE question of competition with German and other foreign shipowners is the subject uppermost in the minds of British shipping people at the present time. And in this regard a startling instance has been cited. Sir Fortescue Flannery, a leading consulting marine engineer, estimates that there is a difference of £2,000 in wages on a round-trip in the Europe-South American trade—of course to the advantage of the German shipowner, whose success in this achievement is brought about by cheap coal, cheap stores and light taxation. But, judging from the rapidity with which the German shipping concerns are augmenting their merchant fleets, the competition in the future will be on still more pronounced lines.

THE NEW "N. D. L." FLEET

Take the case of the Norddeutscher Lloyd. According to official data, the "N. D. L.," as it is more generally known, at all events on this side, is making satisfactory progress in the reconstruction of its fleet and the restoration of its overseas connections. Of the 23 ships which were under construction at the beginning of the 1922 business year, seven steamers, of 49,500 tons, were last year completed and taken into service. The building program has been extended by the addition of two cargo steamers, totaling 12,000 tons gross. Further, the passenger and cargo steamer *Bremen*, of 10,826 tons gross, has been acquired. But that is not all. In the course of this year the steamers *Munchen*, of 13,325 tons gross; *Werra*, of 9,475 tons gross; *Ludwigshafen*, of 5,918 tons gross, and *Aachen*, of 6,274 tons gross, have been completed and taken into service, while the 32,000-ton *Columbus*, so far Germany's largest merchant vessel, is the most recent addition. Furthermore, there are still nine steamers, of about 110,000 tons gross, under construction for the "N. D. L.'s" account.

Well may British (and other) shipowners view with considerable concern the coming competition of the German shipping lines, of which, of course, the Norddeutscher Lloyd is but an example. By the middle of the present year, such progress had been made with the restoration of the N. D. L.'s services that the system comprises a weekly service of passenger and cargo steamers to New York, a service of passenger and cargo steamers every three weeks to Brazil, a monthly service to the Far East, and a service every three months to Australia. Most significant of all is the official prediction that for the current business year a satisfactory business result may be anticipated.

BRITISH SHIPBUILDING NEEDS SUPPORT

Apprehension of this increasing competition of German shipping is apparent in various quarters, but only very occasionally are views put forward showing the feeling that lies beneath the surface. It is not unnatural, therefore, that the opinion expressed by Lord Aberconway, head of the famous

shipbuilding and engineering firm of John Brown and Company, of Glasgow, should have received at the hands of United Kingdom shipping people in particular, and business men generally, a large measure of attention. Lord Aberconway's views on the shipping, shipbuilding and engineering position are interesting, though depressing. He considers that, regarded from a commercial, as well as from a political, point of view, there never was a time when the shipbuilding and engineering trades in the United Kingdom were in greater need of support. He does not remember, in forty years' experience, any period in which there was such a depression. The great shipowning companies, he points out, have more tonnage than they know what to do with. Many of the vessels, especially in the North Atlantic trade, are crossing at a loss except in the busy passenger season, so that the shipowning trade is not in a position to build more ships. The balance sheets show millions of pounds' worth of bills outstanding, and, so far from placing new orders, a great number of firms are paying large sums to get out of contracts. In regard to engineering works, very much the same sort of thing applies.

WHAT GERMAN COMPETITION MEANS

So much for a bird's-eye view of the shipping and industrial position. But it is when he comes to the cause or causes of this depressing situation that Lord Aberconway lets himself go. Asking: "Will trade come to this country, or will Germany get it?" Lord Aberconway quotes a recent contract for a ship, when the tender from a British firm was 40 percent higher than the quotation of a German firm. This means, he says, that Germany can build tonnage at half the cost we can in this country, and he thinks that this reflects the international position. Apropos the marked disparity between British and German costs, Lord Aberconway lays it down that—

"Germany has perpetrated the most enormous swindle the world has ever seen in the depreciation of the mark. She has been seeking for gold in every market—European, Asiatic, American—and there are from 450 to 500 million sovereigns banked in Brussels, New York and elsewhere to the credit of German swindlers. They are the great industrial leaders in Germany. They have spent money in putting their undertakings in order, and in putting in the most expensive machinery and every appliance that modern science can devise out of the money of which the whole world has been robbed. Every form of indebtedness has disappeared, including her debentures and her mortgages, and they have no charges to meet. We must face the problem now presented."

It needs no words of mine to make it clear that Lord Aberconway, at all events, has some very definite views as to the gravity of German competition.

GREEK SHIPOWNERS PAY CREWS LOWER WAGES

One turns, perhaps with a feeling of relief, to shipping competition from another quarter—Greece. Here the ad-

vantage enjoyed by Greek shipowners as compared with British shipowners turns on the question of wages. Two examples will suffice to reveal that in this matter Greece is a competitor of some caliber. Tabulated, the figures are as follows:

(1) Greek steamer, 4,800 tons deadweight. Crew 22. Daily wages bill £6 13s. 4d.	(1) British steamer. 4,200 tons deadweight. Crew 25. Daily wages bill £9 1s. 6d.
Vessel's daily cost, including provisions and stores, but excluding insurance, £12.	Vessel's daily cost, including provisions and stores, but excluding insurance, £14 13s.
(2) Greek steamer. 8,000 tons deadweight. Crew 32. Daily wages bill £11.	(2) British steamer. 6,600 tons deadweight. Crew 32. Daily wages bill £12 9s.

It is in the matter of wages of the crew, as distinct from those of the officers and engineers, that Greek shipowners are able to effect economies. The captain of the Greek 8,000-tonner referred to in the above table receives £26 a month, or 30s. a month less than the master of the British 6,600-tonner. The other wages compare as follows:

Greek steamer. Mate, £20 a month, Second mate, £16 a month. *Chief engineer, £25 a month. Second engineer, £20 a month.	British steamer. Mate, £20 10s. a month. Second mate, £16 10s. a month. Chief engineer, £23 10s. a month. Second engineer, £20 10s. a month.
---	--

*A Britisher.

The third engineer on each vessel receives the same wage, but, while no fourth engineer is carried in the Greek boat, one is employed in the British steamer. The Greek boat's seamen and firemen are paid £2 to £3 per month less than the Britishers, and the steward £4 10s. a month less, while a mess-room boy receives £4, against £8 10s. paid to a mess-room steward on the British boat. These figures obviously speak for themselves.

HOW GREAT BRITAIN PROPOSES TO EQUALIZE MATTERS

Reverting to the general position apropos foreign competition, two proposals have been put forward in United Kingdom shipping circles with a view to equalizing matters. The first of these suggestions is that the union leaders of the seamen should propound a scheme to enable British shipowners to operate the vessels at present laid up or to be laid up, the seamen to accept lower wages—but not so low as on the Greek boats cited, but more nearly representing the pre-war wage, plus the increase in the cost of living. The second proposal is that the government, without infringing on the principle of Free Trade, should tax foreign steamers to the extent of the difference in the rate of wages paid on the respective British and foreign boats.

PROPOSAL FOR GOVERNMENT CREDITS FOR BUILDING MOTORSHIP TONNAGE UNFAVORABLY RECEIVED

A suggestion that the British Government should grant credits to shipowners in connection with the building of motorship tonnage has excited attention in shipping circles, but, judging from its reception, its author might well have left the subject alone, thus saving himself time and thought. He urged that, with the larger volume of motorship tonnage which British shipowners will eventually require, if they are to hold their position in the sea carrying trade, the government should place national credit at the disposal of the shipowners. This, of course, was a direct invitation to the government to take a hand in the future conduct of the British mercantile marine, and, frankly, the British shipping community has expressed its unqualified disapproval of any such course being adopted.

A leading shipbuilder fears that the proposal would not be likely to provide a great deal of employment for shipbuilders in the near future. No doubt, he says, the transition

from steam to internal combustion engines will come about in time, but it will be a slow and gradual process. "Internal combustion engines," says this authority, "are still in a large measure in the experimental stage, and shipowners will not, I imagine, be prepared to embark on extensive programs until they feel more sure of their ground."

A shipowning expert, in voicing his doubts as to the practicability of the proposal, cites the Chamber of Shipping view that shipping should be left alone to develop along its own lines.

SIR ALFRED YARROW SAYS TRAMP VESSELS DESTINED TO BE MOTORSHIPS

Touching on the internal combustion engine, Sir Alfred Yarrow, the famous shipbuilder, states, with regard to Diesel engines, that there is not the slightest doubt that, as long as the oil supplies of the world last, engines of this type will replace those of steam in tramp steamers and other vessels of the same character. In the first place, he says, owners will be inclined to use Diesel engines to maintain a more efficient and cheaper service, and, secondly, because the space and weight saved by carrying less oil fuel gives increased facilities for carrying greater quantities of cargo. Sir Alfred Yarrow thinks that there is also a future for oil engines in passenger ships, but, as for a vessel of the *Beren-garia* type, he considers it will be a long time before they have that means of propulsion. Perhaps his most interesting view, however, is that, within the next twenty years all "tramp" steamers will be running on Diesel engines, unless there are any new discoveries in the intervening time. There is, he thinks, the possibility that, if oil fails to last, owners will have to increase their prices for freight—"which would be a big drawback all round"—but he is of opinion that, for steamers of eleven or twelve knots, the Diesel engine is ideal.

COMPARATIVE OPERATING RESULTS OF MOTORSHIP AND STEAMER

To pursue the question of the advantages or disadvantages (if any) of Diesels, striking comparisons have been drawn here between the operating results of a Diesel-engined vessel, an oil burner and a vessel burning coal. An analysis of these three types of vessels indicates to a marked degree that the balance of profit is decidedly in favor of the vessel driven by Diesels—not, of course, on all voyages, but on those where long distances have to be covered.

The case is quoted of a Diesel-engined vessel which has completed a round voyage occupying more than 160 days. During this period her average daily profit was approximately £4, which, on the surface, is in all truth a small amount, but is, in fact, considerably in excess of the sum gained by vessels of other types. Thus, the receipts of an oil burner would have been reduced by rather more than 6 percent owing to cargo being shut out, and, allowing for minor advantages, such as lower disbursements and reduced insurance premiums, the net result of this oil burner's voyage would be a loss exceeding £3,000, or about £19 per day. The coal-burning steamer's voyage would compare even more unfavorably with the Diesel boat. The larger amount of coal carried would reduce the gross freight by 9.61 percent, and finally the round voyage would show a loss of about £7,400, or nearly £47 per day. To sum up, therefore, the oil-burning steamer would lose nearly £7,000 in a year and the coal burner at the rate of £17,000, while the Diesel vessel would earn the small, but acceptable, profit of £1,460 per annum, ignoring, of course, depreciation or capital interest.

On the general question of Diesels, the big question remains the extra initial cost of construction. Statistics such as those cited above would seem to show that this greater first cost to build is well worth while; but shipowners are not so sure about it, and, frankly, they will take a deal of convincing.

First British-Built Diesel Electric Ship Completes Trials

The Fruit Carrier *La Playa* Is Equipped with Four Camellaird Fullagar Units — New Vickers and Sulzer Oil Engines

By Our Special London Correspondent

IT cannot be said that European shipowners are very favorably disposed towards the adoption of Diesel electric propulsion. Their general opinion is that this involves additional complication, with the result that upkeep costs are higher, and a larger engine room staff may be needed. They fear moreover that the price of the machinery would be high, and they have a conservative objection to the employment of fast running Diesel engines coupled to generators.

the order of American owners, namely the United States Fruit Company of Boston. Incidentally, it is somewhat curious to note how many of the recent motorship orders placed either directly or indirectly on behalf of American interests are being executed in European yards. In addition to the three craft mentioned, the Pacific Mail Steamship Company has two passenger and cargo motorships on the stocks at Gothenburg, the Standard Oil Company has ordered

New Standard 600 Brake Horsepower Vickers Oil Engine

They therefore prefer the slow-running Diesel motor, direct coupled to the propeller shaft, and are not greatly impressed with the claim of the advocates of the Diesel electric system that reliability is increased, since the power is distributed over several units instead of one, or, at most, two.

MOTORSHIPS BUILDING IN EUROPE FOR AMERICAN OWNERS

Nevertheless, the greatest interest has been evinced in the new Diesel electric ship *La Playa* which has just been completed at Cammell Laird's yard at Birkenhead and has run a series of very prolonged trials. It is significant, however, that this vessel, which is the first of three sister ships, is to

motor tankers from Krupps, two 20,000 ton ore carriers, now being built in Germany for Mr. Dan Brostrom, the Swedish shipowner, will be operated on behalf of the Bethlehem Ore Company, while two other motor cargo ships now being constructed in England are for an American concern.

DIESEL ELECTRIC SHIP HAS GREATER CARGO SPACE

The *La Playa* is in many respects a remarkable vessel, and probably represents the most interesting example of Diesel electric propulsion that has yet been seen in any country. She is designed essentially for fruit carrying, has a capacity of 5,000 tons and has the relatively high speed of 14 knots,

speed being of course such an important factor in ships engaged in this trade. The length is 325 feet, the beam 48 feet, and the depth 31 feet 9 inches. The striking claim is made that in spite of the fact that four generating units are installed, there is actually larger cargo carrying space in this ship than in an ordinary motor vessel, mainly on account of the fact that there are no long propeller shafts and shaft tunnels between the main engines and the propellers.

Fitted in the engine room are four Diesel driven dynamos of 500 kilowatts each, the engines being of the four cylinder Camellaïrd Fullagar opposed piston type, each developing 750 brake horsepower and having cylinders 14 inches in diameter, with a combined piston stroke of 36 inches. They run at the fairly high speed of 250 revolutions per minute, being thus very much lighter than the normal slow speed marine direct coupled type. This accounts for the fact that there is very little difference in the machinery weight of this ship as compared with a normal motor driven vessel.

GENERATORS

Each engine actually drives two dynamos, for in addition to the main generator previously referred to, there is an auxiliary of 200 kilowatts output. These auxiliary dynamos supply the necessary power for auxiliary purposes, since electrical machinery was used throughout and there is no boiler on the vessel. It might be thought that four auxiliary generating sets developing a total of 800 kilowatts represents an excessive amount, but the demands for the refrigerating plant are very heavy and are estimated at some 500 horsepower. This is all provided from the auxiliary generators, so that there is no necessity to install auxiliary Diesel driven dynamos which is the usual arrangement of a motor vessel.

Direct current transmission is adopted but the main generators, each operating at 220 volts, being coupled in series thus supply current at 880 volts to the 2,500 brake horsepower electric motor, which is direct coupled to the propeller. Speed control and reversal are accomplished by varying the stroke and direction of excitation of the fields of the main generators, and normally the propelling motor runs at 90 revolutions per minute.

VICKERS BRINGS OUT A 600 HORSEPOWER DIESEL

Although most of the leading British Diesel engine manufacturers concentrate their attention on the construction of motors of 1,000 brake horsepower and upwards, in one or two cases types of smaller power are standardized, as it is thought there is a field for engines of 500 to 600 brake horsepower for installation in small vessels, such as coasters and similar craft. It is with this object in view that Vickers have just brought out a new standardized model of 600 brake horsepower in six cylinders, and the first example is being fitted in a small mixed cargo and passenger vessel recently built for Japan. This is all the more interesting as it indicates competition between Diesel and semi-Diesel engine builders, since motors of the latter class are now being constructed up to 600 brake horsepower as instanced in the Beardmore and Kromhout designs which have already been described in this journal.

The latest Vickers engine is a pure Diesel with their well-known system of solid injection. It has cylinders $18\frac{1}{4}$ inches diameter and 27 inches stroke, and the speed is 150 revolutions per minute. It must be admitted that at first sight it appears somewhat complicated in comparison with a semi-Diesel as it has all the accessories, the valve gear and reversing mechanism of a Diesel motor five or six times the power.

There is a set of fuel pumps seen on the left of the control station, delivering fuel to the fuel valves at 4,000 to 5,000 pounds per square inch, one of which is located in each cylinder cover. The speed is controlled by altering the lift of the fuel valves, this operation being carried out by means of a lever at the control station. Starting is by compressed

air in the usual manner, and ahead and astern cams are mounted side by side on the camshaft which is moved longitudinally by an air servo motor when it is desired to reverse the engine. The exhaust valves are water cooled and the valve levers are all pivoted eccentrically on a layshaft which

Valve Gear of One of the Cylinders of the New Vickers Engine

is turned before reversing, thus lifting the rollers of the valve levers off the cams before the camshaft is moved.

A NEW SULZER DESIGN

In the hope of lowering the cost of production, Sulzers have lately been engaged upon the development of an entirely new design of Diesel engine adapted mainly for low powers. At present, the motor is built only in sizes up to about 300 brake horsepower but there is the possibility of the same system being utilized for larger engines as the results have been

The New Sulzer Valveless Diesel Engine with Crank Chamber Compression

exceptionally good. In the engine illustrated, it will be noted that there is no air compressor and all valves are eliminated.

The motor operates on the two cycle principle and the smaller size has crank chamber compression for scavenging, although in bigger sets, separate pumps can be utilized, and this would, no doubt, prove more satisfactory. The fuel is delivered from a low pressure mechanical pump through an automatic atomizer into an ignition chamber in the cylinder cover. This injection takes place some time before the piston reaches the top dead center.

As the air is compressed on the upward stroke, it enters the ignition chamber through a comparatively small hole, connecting it with the combustion chamber. Partial ignition results, raising the pressure in the ignition chamber and this causes the whole of the fuel therein to be forced into the combustion chamber. The air mixes with the compressed

air and combustion takes place as in a normal Diesel motor. On the downward stroke, the exhaust gases are discharged through exhaust ports and scavenging air enters through ports at the bottom of the cylinder uncovered by the piston.

It is specially worthy of note that the fuel consumption of this engine is about 0.42 pound per brake horsepower hour when running on Diesel oil, a result almost equivalent to that of the best present-day Diesel engine of large power.

Insurance Companies Hard Hit by Japanese Disaster

Early Reports of Marine Losses Greatly Exaggerated—New York Marine Insurance Men Appoint Committee to Handle Japanese Problem

By "Bordereaux"

THERE are few prominent insurance companies in the world that will escape the payment of losses on account of the recent earthquake and fire in Japan. Companies are responsible for the effects of earthquakes and tidal waves, under their regular marine contract, as these are clearly so-called "acts of God." It is likely that a year or more will elapse before satisfactory proofs of loss can be presented to the respective insurers. There still remains a great deal of uncertainty as to the extent of the disaster, but it is generally felt, from the more recent advices received by underwriters, that early reports of marine losses were greatly exaggerated. Only two or three hulls were lost in Yokohama or along the coast; a large number of small craft were in the harbors and inside the breakwaters when the first earthquake shocks were felt and most of the loss incurred as respects hulls was on their account.

Modern massively constructed warehouses along the water front at Yokohama were controlled by Japanese customs officials, and in these the bulk of freight awaiting shipment, and discharged from vessels, is normally found. It is presumed that all records, governmental and private, kept in the Customs Compound have been destroyed. The exact location of any shipment will be a matter of uncertainty and may possibly never be determined beyond a shadow of doubt. Access to customs warehouses in Japan is denied to outsiders.

It is understood that the principal marine companies in Japan wrote large amounts for their own nationals and that those having branches in foreign countries were very active in shipments to and from the Japanese Empire. There are now more than forty companies of Japanese writing a general marine business. Cable advices to the *Nippu Ji Ji*, a Japanese newspaper in Honolulu, says the entire insurance losses in the earthquake zone will total about \$1,100,000,000. Of this sum eighty percent will be paid by the government and twenty percent by the insurance companies.

Steamers entering the Yokohama harbor are making extensive soundings because of the recent upheaval of the sea bottom. It is thought that it will be necessary eventually to make soundings for forty-five miles out, if the true condition of the bottom is to be known. For a considerable time after the earthquake Yokohama harbor remained inaccessible to vessels of the draft of those of the Canadian Pacific Line.

New York marine underwriters have been receiving requests from bankers and shippers that insurance policies or certificates of insurance be amended to cover to original port of destination or to any port in China or Japan to which goods may be diverted because of possible congestion at the intended port of discharge. This was the result of rumors reaching the United States of congestion in Japanese ports. Steamship lines are preparing to handle an abnormally large amount of freight and the Far Eastern Conference has met to discuss the situation brought about by the earthquake. A message has been received from Osaka to the effect that the Navy Department will soon be busily engaged

in scrapping a number of government vessels the material from which is to be used for reconstruction work at Tokio.

Most marine policies cover from warehouse to warehouse, and this doubtless means that the underwriters will sustain serious losses on cargo that was in transit at the time of the disaster. On the other hand, unless special provision was secured from the underwriters, goods delayed in local warehouses known as "godowns" will not be covered beyond a limited period. The earthquake clause is written in most of the policies in effect in Japan, and under it the underwriters are free of liability resulting from earthquakes. In general there is doubtless considerable merchandise still in warehouses in Japan under shore-end cover, and because of the general situation marine insurance men in New York recently met and appointed a special committee to handle the Japanese problem and to arrange to have competent salvage men on the ground as soon as possible.

Bonded Warehouse Pilferage

MARINE insurers are watching with interest and satisfaction the commendable enterprise that is being shown by the Merchants Association of New York, through its foreign trade bureau, in endeavoring to bring about a settled determination of the responsibilities for merchandise lost in bonded warehouses. The ordinary marine policy covers from warehouse and shipper to warehouse and consignee. However, if goods are placed in storage in a bonded warehouse, the marine insurance coverage would terminate, but, if the goods are held in such bonded warehouse for a temporary period and upon being delivered to consignee are found to have been pilfered, the question immediately arises as to where the pilferage occurred; that is, whether on the voyage or after the arrival of goods in the bonded warehouse. This is important to the underwriter because the pilferage bill would be put up to him.

Trade With Turkey

THE restoration of peaceful conditions in Turkey and quiet progress there toward the establishment of a republic are being watched by marine underwriters with great interest as indicating to them the probable revival of trade between that country and the United States. Hope is frankly expressed that, if such a revival should take place, improvement will be made in handling goods at the port of Constantinople. At present underwriters are confronted with heavy claims for damage on shipments to that port. This is particularly true as respects shipments of food stuffs, such as flour, sugar, etc. Apparently the goods are permitted to remain on lighters and in the open on shore for considerable periods exposed to the elements. This results in damage for which the underwriters have to be responsible. Insurers are also complaining that they do not receive fair treatment in connection with the adjustment of losses at Constantinople.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Weights of Fuel Oils

Q. (1,220).—Will you kindly furnish me with the weights per cubic foot or per gallon of the following oils for marine engines—gasolene, kerosene, oil for heavy oil engines, Diesel oil and marine boiler oil? N. L. S.

A. (1,220).—The following figures represent average conditions closely:

Oils	Cubic feet per ton	Gallons per ton	Pounds per cubic foot
Gasolene, boat	49	366.5	45.7
Gasolene, aviation	50	374.	44.8
Kerosene	44	329.1	50.9
Fuel oil (boiler)	40	299.2	56.
Diesel engine oil	42	314.	53.
Lubricating oil	38.5	288.	58.2

So-called heavy oil engines should use ordinary boiler fuel oil satisfactorily.

Diesel engines are capable of burning boiler fuel oil but this is generally unsatisfactory.

Fuel Consumption Problem

Q. (1,221).—A ship making 10 miles an hour makes 1,500 miles on 200 tons of coal. How much coal would be required for the ship to go 1,200 miles making 6 miles an hour?

A. (1,221).—At 10 miles the ship runs $\frac{1,500}{10} = 150$ hours on 200 tons.

This is then $\frac{200 \times 2,240}{150} = 2,990$ pounds per hour.

Assume a consumption of 2.5 pounds per horsepower per hour. Then the horsepower is about 1,200.

Assume a cargo ship 288 by 40 by 18.25 by 4,500 which would be reasonable for such a machinery installation. The power at 6 miles may be taken* at $\frac{1}{3}$ that at 10 miles, call it 400. The coal consumption at this power would be roughly 5 pounds per horsepower per hour. Hence she would consume per hour:

$5 \times 400 = 2,000$ pounds = 0.893 ton
1,200 miles at 6 miles requires 200 hours,
therefore tons of coal required are $200 \times 0.893 = 178.6$, say 180 tons.

*Propulsive coefficient taken as 85 percent that at 10 knots.

Comparative Fineness of Afterbody of Submarine and Destroyer

Q. (1,222).—Please compare the fineness of the after body of an ordinary submarine with that of destroyers or light cruisers.

A. (1,222).—It is somewhat difficult to convey a correct idea of the fineness of an under body without lines and curves of areas of section, which are, of course, impracticable to furnish.

A sufficiently accurate idea for your purpose may perhaps be obtained through the value of the prismatic coefficient of the after bodies in each case. The values of this coefficient in recent light cruisers and destroyers are about 0.63 to 0.64. For a modern submarine the corresponding figure is 0.54.

Effect of Jogging of Frames

Q. (1,223).—What can you say of the jogging of frames as to the effect on weight, strength, cost of construction, etc.?

A. (1,223).—The jogging of frames consists in the off-setting of the frame in way of outside strakes so that the frame bar lays against the inner surface of the strake. Jogging is done cold in a press before the frames are bent.

By jogging frames, liners are eliminated and their weight saved. This weight may amount to about $3\frac{1}{2}$ or 4 percent of the weight of the shell plating. Jogging may be done in frames or deck beams up to a depth of section of 12 inches. Jogged frames, however, are generally hand beveled and this is a disadvantage at the ends of a ship, if the framing is heavy, as the work of beveling becomes very laborious.

The strength of the shape is decreased by jogging but the loss is immaterial.

The advantage of jogging from the standpoint of cost lies in the saving in punching and riveting and in the reduction of the number of pieces to be handled. The actual amount of the saving will depend somewhat on the character of the vessel and the facilities of the shipyard.

Power Required to Drive Vessel

Q. (1,224).—Please tell me how much power I will require to drive a vessel 200 feet by 25 feet by 7 feet draft at a speed of 16 knots.

A. (1,224).—The writer has received similar questions to the above on a number of occasions and has been unable to give a satisfactory answer because the inquiries contained insufficient information. There should be furnished, in addition to that given above, the displacement and the prismatic, midship section or block coefficient. Otherwise no idea of the fineness of underbody or the displacement relative to the length is obtainable.

It is possible to have an infinite number of displacements on the same length and beam. For example, examine the following table:

	Length	Beam	Draft	Displ., Tons	Speed, Kts.	Eff. Hp.	Speed, Kts.	Eff. Hp.
Case 1	200	24	5.5	305	15	335	18	755
Case 2	200	24	6.6	406	15	480	18	980
Case 3	200	25.5	6.25	500	15	470	18	1,110

Cases 1 and 2 are for the same vessel at different drafts, while Case 3 is for a different vessel. Note that the displacement—length coefficient $\left(\frac{\text{displacement}}{\text{length}^3} \right)$

is 62.6 in Case 3 and but 38.1 in Case 1, while the block coefficients are 0.55 and 0.405 respectively. Note also that the effective horsepower at 15 knots is about the same for Cases 2 and 3 while for 18 knots Case 3 requires a good deal more power than Case 2.

The vessels referred to above are suited to relatively high speeds. The following is an instance of a vessel of similar

dimensions but of a very different type and intended for very low speeds:

	Length	Beam	Draft	Displ., Tons	Speed, Kts.	Eff. Hp.
Case 4	200	25	6.5	715	10	200

It would probably be impracticable to put sufficient power in a hull of this type to get a speed of even 15, to say nothing of 18, knots.

LETTER TO THE EDITORS

Combined Riveting and Welding

NORFOLK, Va.

TO THE EDITORS:

Referring to the editorial in your July issue and the letter of N. G. Near in the September issue under the above heading, the writer considers that the reinforcement of riveted joints by the use of metal arc welding would be good practice when it is necessary to increase the strength of existing riveted joints as in the case of the conversion of the battleship *Kearsarge* into a seagoing crane ship, on the other hand the use of metal arc welding to reinforce a riveted joint in new construction would, in general, indicate a lack of faith in both methods of joining metals.

The calculated maximum possible efficiency of any riveted joint is 89 percent as given in the specifications of the United States Navy, and experiments with riveted connections indicate that the loads at which riveted joints begin to open are very much lower than the ultimate strength of the joints.

A lap joint made by an electric arc welder, selected on the same basis as a first class riveter, will invariably fail outside of the joint, if a full fillet weld is made on both edges of the lap. Furthermore it is possible to reinforce both of these fillet welds, thus further insuring that the joint will not fail in the weld. With such assurance there appears no justification for weakening a lap joint by the use of rivets.

Tee, open butt strap, corner butt, and joggled lap (provided the fillet weld on the flush side is not made in the joggle) joints can also be depended on to give 100 percent efficiency, if the proper amount of filler metal is deposited in the weld. This assurance cannot be had for double-bevel or double-vee butt joints, without careful attention to many factors on which the strength of such joints depend, e.g., carbon content of the steel, sequence of welding, reinforcement of the weld, etc., and for this reason it would be better to avoid, at least for the present, the indiscriminate use of these joints in ship construction and repair. When such joints are used they should be reinforced by a strap.

The future application of welding to ship construction, to the exclusion of riveting, is contingent on a thorough knowledge of the factors on which the strength of the welded joint depends, and unless these factors are clearly understood, it will be quite possible to weaken a riveted joint by the use of welding. The writer believes the time will come when it will be thought as unnecessary to test a metal arc welded joint as it is now considered unnecessary to test a brick wall.

Relative to N. G. Near's desire for tests on combined riveted and welded joints, it is believed that such tests conducted by the Quasi Arc Company in England and those conducted by William T. Bonner during the war, the latter of which are given in the "Report of the United States Shipping Board of the Emergency Fleet Corporation on Electric Welding" by Captain James Caldwell, R. E., 1918, will give a clear indication of what can be expected of such a combination.

JAMES W. OWENS, Electrical Engineer, Norfolk Navy Yard. In charge of Welding Research for the Bureau of Construction and Repair of the United States Navy.

NEW BOOKS

The International Combustion Engine

THE INTERNATIONAL COMBUSTION ENGINE (Two volumes). By Harry R. Ricardo, B. A., A. M. I. C. E., M. I. A. E. Size 6½ by 9¾ inches. Volume I—Slow Speed Engines: Pages, 488. Illustrations, 215. Volume II—High Speed Engines: Pages, 373. Illustrations, 225. New York, 1923: D. Van Nostrand Company.

This work is built upon generous lines. The thermodynamics of the internal combustion engine is treated at length, and the application of the various types of engines to stationary practice, aeroplanes, motor cars and the multitudinous uses to which gas engines and similar motors are put is described in detail.

For the shipbuilder and those concerned with marine affairs, however, the book appears to us somewhat disappointing, as the development of the marine Diesel engine, up to the present time, has been greater and is now proceeding more rapidly than one is led to believe by a perusal of its pages. There is in the book no adequate treatment of the Diesel as it stands today in relation to marine development and, in a modern and up-to-date work, this appears a rather serious omission.

For the designer of internal combustion engines the book contains much of interest and should prove a valuable addition to his bookshelf.

Sir Alfred Yarrow

ALFRED YARROW; HIS LIFE AND WORK. Compiled by Eleanor C. Barnes (Lady Yarrow). Size, 5½ by 8¾ inches. Pages, 328. Illustrations, 83. New York, 1923; Longmans, Green and Company.

The name Yarrow is a household word among shipbuilders the world over. There is possibly no man who has attained a greater prominence in the field of marine engineering and its allied arts during the past twenty-five years than Sir Alfred Yarrow. And this enviable and deserved position is but the natural result of signal ability coupled with hard and conscientious work.

Entering the engineering profession as an apprentice at the age of fifteen, Yarrow's inventive and constructive genius carried him forward by leaps and bounds. His first serious invention was a steam plough, patented more than sixty years ago. This was followed by a steam carriage capable of making twenty-five miles an hour.

After that, he turned his attention to the sea, and in 1868 his first steam launch was delivered. From that time on Yarrow's work, as exemplified by his torpedo boats and destroyers, the Yarrow boiler, his development of the science of balancing reciprocating engines—all is well known to the members of his profession.

All this is interestingly recorded, if in a somewhat fragmentary manner, by Lady Yarrow in the biography under review. The book also gives another side to the picture, perhaps not so generally known—the life story of a kindly, lovable and public-spirited gentleman.

The History and Problems of the International Seamen's Union of America

The account of the organization and activities of the International Seamen's Union of America published by the Bureau of Labor Statistics of the United States Department of Labor as Bulletin No. 342 records the efforts of the union over a long period to change the laws of contract relating to seamen.

PERSONAL MENTION

T. S. ROSSBOTTOM has been appointed general manager of the United States Lines in charge of operations.

R. D. YAUCH has been appointed manager of the allocation department of the United States Shipping Board at Washington.

U. J. GENDRON has been appointed manager of the contract department of the Shipping Board with headquarters at Washington.

WILLIAM J. LOVE has resigned as general manager of the Emergency Fleet Corporation to accept the appointment of managing director of the United States Lines.

ALFRED WELLER, formerly assistant to M. A. Kerwin, traffic manager of the Colombia Steamship Company, has been made traffic manager of the company, succeeding Mr. Kerwin.

W. O. HAINES, who has been connected with Norton, Lilly and Company on the Pacific coast staff, has been appointed superintendent at Portland, Ore., for the company's Pacific port service.

CAPTAIN R. D. GATEWOOD, director of the Bureau of Maintenance and Repairs, United States Shipping Board, is in Europe inspecting facilities for the repair of Shipping Board vessels.

FRANK T. LORD of New York was recently named as one of Chairman Farley's aides in the United States Shipping Board. His title is assistant to the president of the Emergency Fleet Corporation.

J. B. SMULL, former president of the Emergency Fleet Corporation, is now actively participating in the business of J. H. Winchester and Company, ship brokers at 17 Battery Place, New York.

E. C. MORSE has joined the organization of the Triumph Electric Company and the Triumph Ice Machine Company, Cincinnati (Oakley), Ohio, as vice-president in charge of sales and member of the board of directors.

COL. R. H. HALLETT, formerly of the legal division of the United States Shipping Board, is now acting as assistant to Chairman Farley. Col. Hallett was at one time assistant director of the Bureau of War Risk Insurance.

F. S. B. HEWARD has joined the board of the Canadian Combustion Engineering Corporation, Ltd., representatives in Canada of James Howden and Company. Mr. Heward still retains his connection on the executive board of the latter company.

M. A. KERWIN, formerly traffic manager of the Colombia Steamship Company, has been appointed traffic manager of the Di Giorgio Fruit Corporation. In addition to this work he will also have charge of the freight and passenger vessels operated by Di Giorgio.

R. H. M. ROBINSON, president of the United American Lines, has severed his connection with the American-Hawaiian Lines, his place being filled on the board temporarily by V. H. Thun, treasurer of the company. A permanent director will be elected at the next meeting of the board to be held in San Francisco.

W. A. HARRIMAN has resigned as chairman of the board of directors of the American-Hawaiian Steamship Company, as a result of the separation of the affairs of the American-Hawaiian Line and the United American Lines, formerly under one management. Mr. Harriman will, however, continue as a member of the board of directors of the latter

company. The office of chairman of the board has been abolished.

A. P. VILLAIN, formerly with the passenger department of the Canadian Pacific, has been appointed district passenger agent of the United States Lines at San Francisco, succeeding Theodore H. Jacobs, who was recently made Pacific coast passenger manager of the United American Lines.

E. S. BOGART AND W. P. RUDROW have become associated with the United American Lines in the inter-coastal department. Mr. Bogart was formerly claims agent for the American-Hawaiian Steamship Company and will act in the same capacity for the United American Lines, while Mr. Rudrow, formerly general freight agent of the North Atlantic and Western Steamship Company, will be east-bound freight agent for the United American Lines.

SIR ALFRED YARROW, the noted British engineer and ship-builder who was a visitor in this country last month, pre-

facied his arrival with the interesting prediction that within twenty years all tramp steamers will be run by Diesel engines unless in the meantime some other invention is developed to supplant this method of propulsion. Although not a Diesel engine builder, Sir Alfred's opinions regarding this field of development command universal attention because of the accurate foresight which has characterized his exceptional career in the design and building of ships and propelling machinery. As early as 1868 Sir Alfred delivered his first steam launch to order.

Since that time his progress of achievement has been marked by milestones such as the day when a torpedo was first mounted on one of his fast launches, the first appearance of the Yarrow boiler, and so on down to the world war when Yarrow boats came into their own.

EDWARD P. FARLEY, chairman of the United States Shipping Board, sailed for Europe on the *Leviathan* on October 20 to make a complete survey of the foreign service of the United States Shipping Board and Emergency Fleet Corporation, located in northern Europe, and to attend the Transatlantic Passenger Conference to be held on November 7 in London. Mr. Farley will visit Great Britain and France and probably Germany, Belgium, Holland and Italy. He will return to the United States the last week in November.

GEORGE GORDON CRAWFORD, president of the Tennessee Coal, Iron and Railroad Company, has been appointed chairman of the dock commission to be in charge of the development of the port of Mobile, Ala., by Governor W. W. Brandon. The sum of \$10,000,000 has been voted for the development of the port of Mobile, and it is intended that the dock commission, headed by Mr. Crawford, will be charged with the organization of the forces to map out and carry on the development work.

CAPTAIN E. M. TROTT, traveling superintendent of the United States Lighthouse Department, with headquarters at Tompkinsville, Staten Island, died recently at West New Brighton, Staten Island. Captain Trott was fifty-three years old and had been in the lighthouse service for more than twenty-five years.

Sir Alfred Yarrow

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

Old Dominion and Southern Pacific Companies Place New Ship Contracts Costing Close to Five Millions

A CONTRACT for the construction of two passenger and freight ships for the Old Dominion Steamship Line has been awarded the Newport News Shipbuilding & Drydock Company, of Newport News, Va., according to official information obtained by MARINE ENGINEERING AND SHIPPING AGE. Semi-official confirmation has also been received of the report that the contract for the construction of a new ship for the Southern Pacific Company has been placed with the Tacoma, Washington, plant of the Todd Shipyards Corporation. It is estimated that the two contracts will involve an expenditure of close to \$5,000,000 and considerable interest attaches to the announcement as it follows on the heels of the placing of close to two and one-half million dollars' worth of new vessel construction by Standard Oil interests.

OLD DOMINION LINERS

The proposed Old Dominion ships are to be of the 3-deck, hurricane deck, coastwise type, 375 feet 6 inches in length by 53 feet beam and 29 feet 9 inches deep. Accommodations are to be provided for about 322 first class passengers, 58 steerage and 289 immigrants. The ships will have about 2,100 deadweight carrying capacity and will be propelled by Newport News Company Curtis turbine engines with Newport News single reduction gears turning single screws, steam being supplied by four Babcock & Wilcox watertube boilers, equipped with superheaters. The engines will develop about 4,750 shaft horsepower.

THE SOUTHERN PACIFIC SHIP

The estimates prepared for the Southern Pacific ship provided for a vessel having an overall length of 445 feet, 57 feet beam, depth to hurricane deck 37 feet 6 inches, draft 25 feet 6 inches, with a deadweight tonnage of 7,000. She is to be a single screw vessel, driven by double reduction geared turbines of 6,000 brake horsepower, steam being supplied by six oil burning watertube boilers at a pressure of 250 pounds. The ship is to be fitted to carry about 237 first class and 111 steerage passengers.

U. S. Cruiser Marblehead Successfully Launched at Philadelphia Yard

THE *Marblehead*, the fourth of five light cruisers built or now building at the plant of the Wm. Cramp & Sons Ship and Engine Building Company, in Philadelphia, was launched on October 9.

The hull is 555 feet 6 inches in length overall, 550 feet between perpendiculars and 55 feet in breadth at load waterline. With a designed speed greater than 35 knots, the vessel has a trial displacement of about 7,100 tons with a mean draft of 13 feet 6 inches. At full load the draft will be over 15 feet.

PROPELLING MACHINERY

Propulsion is by four propellers, each driven through reduction gearing by cross-compound Parsons turbines, and, in addition, geared cruising turbines are provided for additional economy at speeds of 20 knots and below. At maximum power the main turbines are capable of developing 100,000 shaft horsepower. Steam is supplied by 12 express type watertube boilers, burning oil fuel.

The main battery consists of twelve six-inch 53-caliber rapid fire guns. The secondary battery consists of two three-inch 50-caliber anti-air-craft guns and two three-pounders. Two triple and two twin above-water torpedo mounts are also provided.

Sun and New York Shipbuilding Companies Awarded Contract for Five and Three S. O. Diesel Oil Barges

THE Sun Shipbuilding Company, of Chester, Pa., and the New York Shipbuilding Company, of Camden, N. J., were the successful bidders for the construction of Diesel-engined oil barges, proposals for which were received by the Standard Transportation Company, a subsidiary of the Standard Oil Company, on Thursday, September 27. The Sun Company has been awarded the contract for five of the vessels and the New York shipbuilding plant, three. Although official figures were not given out, it is understood that the larger contract will involve close to \$1,500,000 and the other about \$900,000.

The new vessels are to be similar to those previously constructed by the Sun Company and according to specifications are to have a length overall of 260 feet, beam molded 40 feet, draft molded 14 feet, and constructed with nine oiltight bulkheads. Each vessel is to have a capacity of 13,500 fifty-gallon barrels of oil on a 12-foot draft.

The main propelling machinery will consist of two 300 brake horsepower, 6-cylinder, 4-cycle, direct reversible, air injection, Diesel oil engines, turning twin screws.

Word comes from the Union Shipbuilding Company, Baltimore, Md., of the company's reorganization of their Repair Department.

American Bridge Co. Gets \$269,250 19-Barge Contract

THE Chief of Engineers, Washington, D. C., has awarded to the American Bridge Company, Pittsburgh, Pa., a contract for the construction of 19 steel barges, 15 to be constructed with cargo boxes at a cost of \$215,250, and four without cargo boxes at \$54,000, involving a total of \$269,250.

The boats are for the District Engineer Office, Louisville, Ky., and are to have a length of 110 feet, beam 26 feet, depth 6½ feet. Bids for the work were opened at Louisville on September 11, the American Bridge Company being the low bidder.

Steamship Owners Urge Revision of Navigation Laws

PRESIDENT Alfred Gilbert Smith of the American Steamship Owners' Association has completed the selection of a special committee of practical ship managers and operators to prepare a thoroughgoing revision of the navigation laws and rules of the United States, including the La Follette Seamen's Act and the laws and rules of the Steamboat Inspection Service. This committee from the Ship-owners' Association will seek the active co-operation of the Department of Commerce and the Shipping Board.

The committee as selected by President Smith is as follows: Captain Eugene E. O'Donnell, manager of the marine department of C. H. Sprague & Son, of Boston, chairman; J. D. Tomlinson, vice-president of the American-Hawaiian Steamship Company; David T. Warden, manager of the marine department of the Tide Water Oil Company; A. J. McCarthy, manager of the American flag steamers of the International Mercantile Marine Company, and Robert F. Hand, assistant manager of the marine department of the Standard Oil Company of New Jersey.

Captain O'Donnell, Mr. Warden and Mr. Hand were among those who participated in the inquiry of the special committee created several years ago by the Shipping Board to make a study of the navigation laws and rules. This former committee included representatives of the seagoing officers and men, and was headed by P. A. S. Franklin, president of the International Mercantile Marine Company. Its work will be a foundation for the present inquiry. The purpose is to have definite recommendations in hand in time for consideration at the coming session of Congress.

Great Lakes Engineering Works to Build One of Ford Ships

THE Great Lakes Engineering Works, River Rouge, Mich., has been awarded the contract for one freight ship for the Ford Motor Company, of Detroit, Mich., according to official information received by MARINE ENGINEERING AND SHIPPING AGE. It is understood that the proposed vessel will have an overall length of 611 feet and be propelled by Diesel engines. Bids for the hulls were taken recently and it is reported that the contract for the second ship has been placed with the American Shipbuilding Company.

Details regarding the construction of the vessels and their equipment have been withheld by the Ford Company.

New Steamer is Under Consideration By Matson Line

ACCORDING to a recent statement by E. D. Tenney, president of the Matson Line of San Francisco, the construction of a new liner with speed enough to make the run from San Francisco to Honolulu in four and a half days is being considered by the officials of the company. The fastest of the company's liners now makes the trip in five days, twenty-two hours.

New Contracts

SEVERN and a half million dollars worth of new vessel construction, a large portion of which has been listed as "pending" for many weeks, has been placed and the maritime industry looks ahead with renewed courage. One of the outstanding features of the awarding of contracts for eleven ships, eight for the Standard Oil Company, two for the Old Dominion Steamship Line and one for the Southern Pacific Company, is the significance attending the building of the oil boats.

Businessmen point out that when the downward trend of affairs is apparently at its worst and the outlook is the blackest, the Standard Oil interests come into the market and buy. For this great purchaser to order, at this time, eight Diesel-propelled, seagoing carriers is taken as an indication that prices are not going lower and NOW is the time to place new contracts.

With these three companies, representative of the nation's leading financial leaders, coming into the marine market at present augurs well for the future of American shipping. Further, the placing of this new constructive work in four different shipyards in different parts of the country sounds a cheering note for the employment of heretofore idle hands—and is not without its bright side for equipment manufacturers.

There are other contracts still under contemplation. If the events of last month are a criterion, and if any faith can be pinned to the judgement and foresight of our big business men, additional contract awards are coming in the not far distant future.

Survey Reports 356 Shipping Board Vessels Available for Conversion to Diesel Ships; Repair Needs Shown

CHAIRMAN FARLEY of the Shipping Board has made public the report of the Board's Fleet Survey Committee, composed of Commissioners O'Connor, Chairman, and Commissioners Benson and Plummer. This Committee has been working for months to obtain the data upon which the report is based, and it covers a complete record of the laid-up fleet, and also divides the fleet into various qualifications as to type, condition, and economy of operation. The following sub-divisions have been made:

SURVEY RESULTS

Class A. 427 steel vessels. Composed of steel of good design, well built, with reliable machinery and deck auxiliaries, capable of continuous operation with normal up-keep. Not requiring in excess of \$35,000 for repairs.

Class B. 177 steel vessels. Of the same as Class A, but requiring repairs and overhauling in excess of \$35,000 each. This expenditure would allow either a greater amount of repairs and overhauling on the replacement of faulty deck or engine room auxiliaries or renewals of gears, etc., which would bring them in Class A.

Class C. 84 steel vessels. Good type and well built hulls in fair state of preservation, but less desirable than A and B, by reason

of unreliable and uneconomical machinery, which, however, could be replaced with reliable and economical equipment at cost of not to exceed \$100,000 per ship.

Class D. 356 steel vessels. Includes vessels of good design and competitive type but fitted with machinery that will require extensive renewal in varying degree, and are desirable hulls for conversion to Diesel propulsion.

Class E. 175 steel vessels. Vessels not considered suitable for American-flag operation.

Class F. 40 vessels. Obsolete types and too old to be rejuvenated or too badly damaged to be serviceable.

SPECIAL TYPE

Army Transports—5. Considered competitive units and in good condition.

Passenger vessels—33. Including 535's, 500's and ex-enemy vessels, 30 of which are in spot condition with 3 laid up and being considered for reconditioning.

Tugs—35. Steel ocean-going, coal and oil burners; wood ocean-going, oil burners and harbor tugs. 6 in operation—9 laid up but in fair physical condition.

In addition to the above there are 362 ships in operation. These vessels have not been individually surveyed, as they are in good operative condition.

Bids Open Nov. 5 at Nashville for 90-Foot Snagboat

SEALD proposals will be received until November 5, by the United States Engineer Office, Nashville, Tenn., for one steel snagboat hull. The boat is to have a length molded of 90 feet, breadth molded 25 feet, depth molded at sides 3 feet 6 inches. The "A" frame will be about 30 feet long and there is to be one upright hand capstan of approved make, having a barrel 9½ inches in diameter over whelps.

The boat is to be delivered afloat at Fox Bluff, Tenn.

Shipping Board Turns Money Into Treasury

Chairman Farley of the United States Shipping Board has made public a letter to the Secretary of the Treasury showing that the Emergency Fleet Corporation had transferred to the general fund of the Treasury over \$37,000,000 as the result of liquidation of the board's war-time activities.

The above amount, together with \$61,808,729.48 deposited to the credit of the "Construction Loan Fund" as directed by Congress, makes a grand total of \$99,435,312.71, which has been deposited in the Treasury during the past two years.

City of Philadelphia to Vote on Issue of \$8,923,000 for Carrying on Extensive Port Expansion Plan

ON November 6, 1923, the city of Philadelphia will vote on a loan, the marine content of which provides for a total of \$8,923,000 worth of port work. It is also understood that provisions are being made for the construction of six mud scows, at an estimated total cost of \$120,000, the pier and boat work to be carried on by the Department of Wharves, Docks and Ferries, of which George F. Sproule is the Director. Among the items of port work are the following:

Toward the acquisition of real estate for the approaches to and erection and construction of the approaches and superstructure of

the Delaware River bridge, \$5,623,000; toward the acquisition of real estate and real estate easements, and for the erection, construction, improvement and equipment of wharves, docks, bulkheads and the work appurtenant and adjacent thereto, \$2,000,000; toward the cost of acquiring land for approaches to and the erection and construction of approaches and superstructure of the Delaware River bridge, \$800,000; for the erection and construction of bridges, \$500,000.

Funds will also probably be used toward the completion of Piers 82 and 84 South, foot of Wolf and Porter streets, Delaware River.

Twenty Steel Barges and Two Double Dipper Dredges Proposed by Engineer Office, Louisville, Ky.

THE construction of twenty steel barges, at an estimated cost of approximately \$300,000, is planned by the United States Engineer Office, P. O. Box 72, Louisville, Ky. Plans and specifications are now being completed.

It is understood that two of the boats (Lot A) will have a length of 120 feet, beam 36 feet, depth 7 feet 6 inches; two (Lot B) will have a length of 100 feet, beam 25 feet and depth 5 feet; and sixteen (Lot C) are to have a length of 110 feet, beam 26 feet, depth 6 feet 6 inches. Fourteen of the boats under Lot C are to be constructed with cargo boxes.

TWO STEEL DREDGES

The same office expects to ask, in the near future, for bids for furnishing and delivering machinery and plans for two steel

dredges. A complete description of the dredge machinery and plans, including dimension of machinery, size and boilers, gear, etc., together with drawings to show the layout, method of operation, and the hull of the proposed dredges, will be asked for.

The dredges are to be steam operated, equipped with a Scotch marine type boiler with water back and designed for a working pressure of at least 125 pounds. The vessels are to be capable of dredging compacted gravel, the machinery to be designed for a 4-yard dipper in hard gravel and a 2½-yard dipper in rock. Each dredge will be equipped with two dippers, one for rock and one for sand and gravel.

The dredges should draw not over 4 feet, when completely outfitted and loaded with 30 tons of coal.

Towboat and Barges Planned by Western Barge Line

It is reported from Omaha, Nebraska, that the Western Barge Line, a newly organized company of that city, plans the construction of one towboat and four to six barges to operate on the Missouri River. The tug is to have an overall length of about 108 feet, beam 24 feet, depth 3½ feet, and is to have a 15-foot stern wheel. The barges will have a draft of 6 inches light and 30 inches loaded.

Gas Manufacturers to Co-operate with Welding Schools

The Gas Products Association, 140 S. Dearborn street, Chicago, Ill., recently appointed an educational committee to co-operate with trade and technical schools all over the country in supplying a practical and standard course in welding procedure. The committee will endeavor to build up a list of accredited schools which are known to give a standard instruction, and whose students can be depended upon to qualify as satisfactory welding operators. It is proposed to make this educational movement effective all over the country.

Launching the Fuel Ship Whitney at the
Boston Navy Yard. The Vessel
Will Cost About \$8,000,000

World's Shipbuilding Reaches Low Level

WORLD construction at the close of quarter just ended was smaller than at any time since the close of the war, Lloyd's Register states, and this represents a decline of more than 165,000 gross tons in comparison with the preceding quarter, ending June 30, last. In the past three months the aggregate of American construction decreased 34,000 tons, that for Great Britain and Ireland, 66,000 tons, and for all other countries combined 65,000 tons.

The following table shows in gross tons the comparison of construction orders now, as compared with three months ago:

	October 1	July 1
Great Britain and Ireland.	1,271,195	1,337,759
United States.....	99,383	133,660
Other countries.....	1,007,119	1,072,437
World total.....	2,377,697	2,543,856

If only construction on which work is actually proceeding is taken into consideration, however, Lloyd's Register points out, the present aggregate is 229,000 tons less than three months ago. Contracts on which work has been suspended in Great Britain and Ireland now represent 242,000 tons, as against 83,000 tons for all other countries. The actual construction now under way, therefore, compares with that of the previous quarter as follows, the figures representing gross tons:

	October 1	July 1
Great Britain and Ireland.	1,029,195	1,207,759
Other countries.....	1,023,502	1,074,097
World total.....	2,052,697	2,281,856

It will be seen, therefore, says Lloyd's Register, that while the actual work in British shipyards has decreased more than 175,000 tons since July 1, that in all other countries taken together has fallen off only 50,000 tons. As a result, British plants, which three months ago were constructing 133,000 tons more than all the rest of the world combined, are now building only about 5,000 tons more.

Idle French Shipping Decreases

A STEADY decline in the number of idle French ships reported in the first half of 1923 is reported by the *Journal de la Marine Marchande* of August 16, forwarded the Department of Commerce by Commercial Attache C. L. Jones. Idle French tonnage as of January 15, April 15, and July 15, 1923, is shown in the following table:

Date	Number	Tonnage	Percent of total
Jan. 15.....	530	845,255	23
April 15.....	450	796,247	21
July 15.....	409	561,382	18

The figures for July 15, compared with those of April 15, show a decrease of 14 percent in the number of idle ships and of 17 percent in idle tonnage. The total idle tonnage on July 15 constituted 18 percent of all the French merchant marine.

Cannery Buys Shipyard

Word comes from Seattle that the wooden shipbuilding plant at Houghton Lake, Washington, originally known as the Anderson Yard, has been purchased by the Alaska Consolidated Canneries from the Lake Union Drydock and Machine Works. The new owners will continue the yard in commercial business.

First American-Built Doxford Diesel Proves Its Value in the Miller County

THE *Miller County*, an 11,000-ton dead-weight oil tanker owned by the Sun Shipbuilding Company, one of three sister ships equipped with engines of the Doxford two-cycle, four-cylinder opposed piston type built by the Sun yard, arrived in New York Harbor September 27 after a practically perfect run from Tampico with a cargo of Mexican crude oil for the Warner-Quinlan Company at Carteret, N. J. The Doxford engine in this ship is the first to be built in this country and has proven satisfactory in every way for the entire 15,000 miles which the ship has made since she was changed from a turbine drive.

VESSEL BOUGHT FROM SHIPPING BOARD

The hulls for the three ships, the *Miller County*, *Bidwell* and *Challenger*, were bought from the United States Shipping Board and converted by the Sun Shipbuilding Company plant, Chester, Pa. The *Miller County* is about 460 feet overall length, 60 feet beam and 27½ feet draft with a dead-weight of 11,000 tons at this draft. Her main engine is of 3,000 indicated horsepower driving a single screw. One Scotch boiler was retained from the former installation to supply the auxiliaries which are all steam operated, as well as for the tank heating coils. The engine complete, including the thrust shaft and fly wheel, weighs approximately 370 tons.

PERFORMANCE OF THE ENGINE

On her voyage from Tampico the engine developed 2,820 indicated horsepower at 71.1 revolutions per minute with a fuel consumption of 0.344 pound of oil per indicated horsepower per hour. Each cylinder developed exactly 705 indicated horsepower for the trip, the exhaust temperature averaged 630 degrees F. With a fuel pressure of 8,000 pounds, her average speed was about 11 knots. On the 2,030 miles run the total fuel consumption was 72 barrels of Texas crude oil. With Diesel oil of 23 degrees Beaumé better fuel economy is expected.

The performance of the Diesel engine in this ship is strikingly brought out by the fact that the single boiler supplying the auxiliaries consumed nearly as much fuel during the voyage as the main engine.

The second ship to be equipped with a Sun-built Doxford engine has steam driven auxiliaries also, but the *Challenger*, the third of the class, will be fitted with electric-driven auxiliaries throughout.

Navigation School Reopened at Seattle

According to announcement from Seattle, Wash., the University of Washington has announced that as a part of its extension service program it will reopen the Navigation School at the University Observatory. The school was conducted during the war by the United States Shipping Board, but its activities were discontinued two years ago when the Shipping Board withdrew from the enterprise because of lack of funds.

Shipping Board Awards Fuel Oil Contract

As the result of competitive bids opened October 1 for furnishing 1,065,000 barrels of fuel oil to the Shipping Board per month for the calendar year 1924, the contract has been awarded to the Standard Oil Company of New Jersey.

Motorship *Suphenco*, of 5,350 Tons Deadweight Capacity, Operated by the Transmarine Lines

Car Ferry *George H. Walker* Goes Into Service

THE Gulf Coast Lines have put in service at Baton Rouge, La., a new transfer steamer, the *George H. Walker*, to ferry its trains across the Mississippi river.

The new boat is of steel, 340 feet long, 91 feet 6 inches wide with a molded depth of 11 feet. It was built by the Dravo Contracting Company, Pittsburgh, Pa., and cost over \$250,000. It has three tracks and can carry 12 passenger cars or 21 freight cars.

The boat is propelled by independently operated side wheels driven by two engines each developing about 600 horsepower from boilers carrying 200 pounds steam pressure.

New Hudson River Day Line Boat Launched

The excursion steamer *Alexander Hamilton* built by Bethlehem Ship Building Company at Sparrows Point for the Hudson River Day Line, was launched October 20. The completed vessel will cost \$1,000,000.

The new boat is 348 feet in length, 77 feet beam and 13 feet deep. She has a capacity of 4,000 persons.

The vessel will be equipped with four Scotch oil-burner boilers, and she will be capable of making slightly over twenty-one knots.

Steel Tug Contract Goes to Howard Shipyards

The American Steel & Wire Company has awarded a contract for a \$150,000 steel tow-boat to the Howard Shipyards, Jeffersonville, Ind. The boat is to have a length of 165 feet, 32 feet beam and 6 feet draft. She will be equipped with compound condensing engines, having a 7-foot stroke.

New Dry Dock in Tampico

One of the important building propositions now being developed in Mexico is the dry dock in Tampico which will be the largest on the east side of America from Galveston to Panama. This dry dock will be built at Buckley Island on the Panuco River and as a part of the project shops and shipyards will be erected.

Transmarine Motorship Completes Maiden Voyage

WITH the arrival of the M. S. *Suphenco* at Port Newark, N. J., on October 9, the first Transmarine motorship, completed its maiden voyage to the Gulf cities of Pensacola and Port Arthur and return. This voyage, totaling over 5,000 nautical miles, afforded ample opportunity

The *Suphenco's* 1,800 Horsepower Diesel Engine

to show the merits of the vessel's Diesel engine. Averaging a little better than 10 knots, the *Suphenco* consumed 4½ tons of fuel oil a day. The fuel oil carried by the *Suphenco* permits a cruising radius of 38,000 miles.

The engine is a 6-cylinder, 4-cycle cross head Craig-Diesel having a 30-inch bore and 4-foot stroke, operating at a maximum of 100 revolutions per minute. The main bearings, crank shaft and piston are water cooled.

One of the features of the engine is the elimination of the customary air compressor attached to the main crank shaft. The fuel air is injected by compressor as usual but this is supplied by an auxiliary unit. All deck machinery, winches, windlass, steering gear together with engine room pumps and auxiliaries are operated by electricity with specially designed marine Elco motors.

Foreign Shipping and Shipbuilding Activities

Italian Line Orders Three Steamers

THE Societa in Azioni Navigazione Libera-Trientina, of Trieste, has placed an order with a local shipyard for three steamers. The company already owns twenty-eight vessels, all engaged in the ocean tramp trade and ranging from the *Rosandra* (7,756 tons gross) to the motorship *Sesta* of 107 tons gross. It is understood that the new vessels will be of the *Laguna* (5,400 tons gross) type.

Canadian Yards Inactive

ADVICES from Ottawa state that business is dull in Canadian shipping and shipbuilding circles. On July 31 there were 132 more vessels of all kinds on the Canadian register than there were at the end of 1922, still the net tonnage was about 69,000 tons less. Quite a few boats are being built, but these are being offset by removals, the latter being so well looked after that there is now but little, if any, deadwood on the register.

Montrose Yard to Build Passenger Steamer

AN order has just been placed with the Coaster Construction Company, Ltd., Montrose, for a passenger day service steamer for the Union Steamship Company of British Columbia. This will be easily the largest vessel ever built in Montrose, as she is to be 236 feet over all and 40 feet in breadth. The steamer will be handsomely fitted up with a large dining saloon capable of being used as a dancing saloon, a large lounge, staterooms, smoking room, etc. Space will be reserved forward for the carriage of a certain amount of general cargo. The vessel will be completed early next year.

Steamship Voltaire Completed

The new Lamport & Holt liner *Voltaire*, built for service between New York and South America, will leave Liverpool on her trial trip November 15.

Launching of the 8,000-Ton French Cruiser Duguay-Trouin at Brest Dockyards on August 14. Her Engines Will Develop 110,000 Horsepower

Wreck of Fourth French Steamer Starts Investigation—Naval Building Program

By Our Paris Correspondent

THE principal event in connection with French shipping which has taken place in the last month is the wreck of the cargo steamer *Depute-Emile-Driant*, belonging to the steamship company Les Armateurs Français, which capsized on August 30 when she was proceeding from Newcastle-on-Tyne to Rouen with an important cargo of coal. That vessel belonged to the series of the *Marie-Louise*, also known in this country under the name of the series of the *Deputes*, three of which have already been wrecked within two years.

The vessels of that type belonged to the State merchant fleet which was liquidated in 1922: the first vessel of the series, the *Marie-Louise*, which was owned by a private firm, was taken as a model by the Department of Merchant Marine when the Government de-

cided during the war to build merchant ships. The vessels were built by naval dockyards under the supervision of naval architects of the Admiralty. It is pointed out that various alterations in the original design were brought about by the latter, and it is hinted that any imperfections in the ships might have been caused by those alterations.

EXPERTS INVESTIGATE SEAWORTHINESS OF THE VESSELS

The three other vessels of the series which have been wrecked are the *Depute-Raoul-Briquet*, the *Depute-Gaston-Dumesnil* and the *Depute-Albert-Taillandier*. Following the wrecks of these three vessels, the Under Secretary of State for Mercantile Marine appointed in 1922 a committee of experts with a view to making a careful examination on the seaworthiness of the vessels of that type. The experts stated that the seaworthiness of these ships was reliable provided that some alterations were made in order to minimize the chances of the recurrence of such disasters.

The chief feature of the construction of these ships lies in the existence of lateral tanks situated in the upper part of the hull. The committee recommended that henceforth these tanks should not be filled. Apart from that particularity, it is now ascertained that these vessels have an abnormal aptitude to rolling and that the exaggerated rolling in a rough sea involves a considerable displacement of the cargo in the holds which results in the capsizing of the ships.

The four vessels were wrecked under similar conditions, without any professional fault having been committed by the shipmaster, and it is now certain that an imperfection in the construction which has still to be ascertained has been the cause of the four

French Destroyer Ensigne Gabolde

On her official six-hour trial this vessel, built by Chantiers & Ateliers Augustin Normand at Havre, made an average speed of 33.45 knots or 2.5 knots more than her contract speed.

successive wrecks which entailed the loss of 45 lives. The Under Secretary of State for Mercantile Marine has just appointed a new committee of experts who have been entrusted with the task of settling definitely the question of the seaworthiness of the vessels.

CRITICISM AROUSED

The keenest emotion has been felt in the whole country as a result of the new disaster, and there is much speculation in respect to the conclusions of the experts. It is noteworthy that eleven vessels of the same type are still in service in this country. Many papers have echoed the general feeling and the criticism expressed against the Under Secretary of State for Mercantile Marine, and the naval architects who drew up the plans of the ships, and they have requested that the eleven ships still in service be at once laid up in order to avoid the recurrence of such disasters, pending the decisions to be arrived at by the experts.

The principal dimensions of the vessels of the *Marie-Louise* type are: Length, 266 feet 8 inches; breadth, 39 feet 4 inches; depth, 22 feet 11 inches; gross tonnage, 2,310 tons.

NAVAL SHIPBUILDING PROGRAM

Considerable interest has been aroused in connection with the launching of the new cruiser *Duguay Trouin*, which took place at Brest on August 14 last. This is the first cruiser launched in France since the war. The *Duguay Trouin* belongs to the naval building program which was ratified by Parliament in 1921. Two other cruisers are under construction, also in naval dockyards: these are the *Primauguet* and the *Lamotte-Picquet*. The three cruisers are to be completed in 1925.

Private shipyards are also concerned in the construction of these warships, and it is noteworthy that the orders placed by the Department of Navy have much improved the position of some shipbuilders. The propelling machinery of the three cruisers is to be supplied by three private shipyards (Chantiers de Saint-Nazaire-Penhoet, Chantiers de la Loire and Forges et Chantiers de la Méditerranée). It will consist of turbines of the Parsons type developing a total of 110,000 horsepower. The cruisers, which will be quadruple-screw ships, are to maintain a service speed of 33 knots.

In addition to these three cruisers, the Department of Navy placed some months ago important orders with private firms in connection with the construction of 4 destroyers, 12 torpedo-boats and 12 submarines. All these warships are to be delivered in 1925.

CONVERSION OF THE FRANCE TO AN OIL BURNER

The French Line is making preliminary arrangements for the conversion of the liner *France* to an oil burner which is to be completed at Saint-Nazaire by the Chantiers et Ateliers de Saint-Nazaire-Penhoet on May 4, 1924. A general overhaul of the boilers of the liner will be carried out together with the transformation work. One hundred and twelve new combustion chambers which have been supplied by the Chantiers de la Seine Maritime are to replace the old ones.

For the execution of this work, the total cost of which will exceed 10 million francs, the Chantiers de Saint-Nazaire-Penhoet have requested the assistance of several other shipyards of Saint-Nazaire. The oil burning plant is to be supplied by the Wallsend Slipway Engineering Company on the Wallsend-Howden system which has already been installed on the *Paris* and several other ships of the French Line, as well as on most of the French oil burners.

Following her reconditioning, the *France*

will be capable of maintaining a service speed of 21.5 knots. She will sail from Havre on her first voyage as an oil burner on May 10. It will be remembered that the *France* was built in 1912 by the Chantiers de Saint-Nazaire-Penhoet. She is 689 feet 2 inches long, 75 feet 6 inches beam and 48 feet 5 inches deep; her displacement (loaded) is 27,192 tons, her gross tonnage 23,666 tons. The propelling machinery consists of 4 steam turbines each driving one propeller shaft. The total power developed is 42,000 horsepower. Steam is supplied by 19 boilers.

Two Large Steamers for Canadian Pacific Coastwise Fleet Planned

E. W. Beatty, K.C., president of the Canadian Pacific Railway, recently addressed a meeting of the Vancouver board of trade and announced that his company proposes to add two large modern steamers to its coast fleet, immediately, to take care of increasing tourist traffic. He also announced the early completion of a new pier at the harbor to cost several millions of dollars.

TRADE PUBLICATIONS

BUYING RUST PROTECTION.—The Eagle-Picher Lead Company, Chicago, Ill., has prepared a booklet on selecting a rust-proof paint and the features which determine its economy. Data on this subject is of valuable assistance in the selection of efficient, labor-saving economical paint for metal protective surfaces. In addition to taking up the cost of painting new surfaces, it also gives information on the preparation and re-painting of surfaces with sublimed blue lead.

WELDING CABLE.—Two announcements by the Rome Wire Company, Rome, N. Y., have been published describing special extra flexible electric welding cable and special-service cord. Many applications of these two types of cord, the first for welding outfits and the second for a variety of shop and household uses, are outlined.

SWITCHBOARD INSTRUMENTS.—Bulletin No. 450 of the Roller-Smith Company, 233 Broadway, New York, deals with alternating current switchboard instruments, including ammeters, voltmeters, single phase and polyphase wattmeters, frequency meters, power factor meters, synchroscopes, ground detectors, transformers, etc. Illustrations and specifications of each instrument are given together with a price list.

INDICATING AND RECORDING CO₂ METERS.—The Brown Instrument Company, Philadelphia, Pa., has sent out catalogue No. 30 describing electrical meters for the measurement of CO₂ content and temperature of flue gases. The efficient combustion of fuel requires an accurate knowledge of the combustion products. The meters designed by the Brown Instrument Company, it is stated, have been found satisfactory in meeting the demands of industrial operation. The principles of operation and maintenance of this equipment are included in the catalogue.

POLYPHASE INDUCTION MOTORS.—Motors of rugged construction and reliable in operation to meet severe requirements of land and sea service have been developed by the Burke Electric Company, Erie, Pa., and details of these polyphase induction motors are given in a bulletin recently sent out by the company. It is stated that these motors have been applied in practically every indus-

try in which electric drive has been adopted and are arranged for side wall or ceiling suspension and furnished with vertical or back gears to meet special requirements.

MECHANICAL OIL BURNING SYSTEMS.—The low pressure mechanical oil burning system, known as the Scarab-Coen has been described in a catalogue prepared by the Scarab Oil Burning Company, Ltd., Carlton House, Regent Street, London, England. This system has been fitted to over 1,000 installations of which the marine section exceeds a tonnage of over four and a half million ships. The company recommends this booklet to those interested in the question of economic steam production.

ELECTRIC RADIATORS.—The electro-vapour radiators put on the market by Walter Kidde and Company, New York city, are explained in a booklet now being distributed. This radiator gives by the turn of a switch the same heat electrically as the usual steam or hot water radiator and can be adapted to any installation where the usual cast iron radiator is installed.

FLOOR AND BENCH GRINDERS.—The two-wheel floor and bench grinders, manufactured by the Hisey-Wolf Machine Company, Cincinnati, O., are illustrated and described in detail in a new bulletin prepared by the company. Floor stand grinders are made in seven sizes ranging from ½ to 10 horsepower capacity, while the bench grinders are in two sizes of ½ and 1 horsepower capacity. The special features of these grinders are outlined with specifications and other details.

DIESEL YACHTS.—Cox & Stevens, New York city, has sent out a pamphlet which was recently prepared on the use of Diesel engines in yachts. The effect that this type of engine has on yacht design is fully discussed. This firm has designed a number of highly successful Diesel yachts, some of which have been built in this country and others abroad. A number of special type yachts are described in more or less detail and illustrations given of the completed designs. The book contains valuable information on the subject of Diesel engines in general and some interesting comparisons between what can be accomplished in cruising yachts powered with Diesel engines and those fitted with other types of machinery in connection with accommodations, cruising radius and cost of operation.

WELDING AND CUTTING EQUIPMENT.—The Torch Weld Equipment Company, Chicago, Ill., has issued a new catalogue covering its complete line of oxy-acetylene welding and cutting apparatus, lead welding, soldering, brazing, decarbonizing units, gas pressure regulators, automatic machines, generators and supplies. The catalogue contains cross sectional views of equipment with detailed explanations.

Business Note

Walter Kidde & Company, Inc., 140 Cedar street, New York, announce that the Lux System is now exclusively manufactured and sold by them in the United States of America. With the Lux System a container storing fifty pounds of carbon dioxide under pressure can be released in forty seconds depositing carbon dioxide "snow" at a temperature of less than -100 degrees F. upon the fire thereby cooling the charred mass in addition to extinguishing the fire by smothering it. The Lux System may be combined with the Rich System of smoke detection, using the same piping, thereby affording a fire detecting and extinguishing equipment for closed compartments.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPBUILDING AND REPAIRS

Repairs, Philadelphia, Pa.—The steamship G. A. Flagg is undergoing repairs at Cramp's shipyard.

Engine Repairs, Seattle, Wash.—Repairs were made on the engine of the steamship Queen recently.

Wood Steamer Repairs, Norfolk, Va.—The wooden steamer Mendora has been towed from Baltimore to Norfolk for repairs.

Spudding Engines, Nashville, Tenn.—U. S. Engineer Office, Customhouse, Nashville, Tenn., is in the market for two spudding engines.

British Steamer Repairs, Seattle, Wash.—As a result of grounding the British steamer Sunland has been drydocked at Seattle, Wash.

Repairs, San Francisco, Cal.—Smith & Scanlon were low bidders at the opening of tenders, recently, for repairs on the Pacific Mail liner Newport.

Steamer Drydocked, Portland, Ore.—The steamer Astorian, one of the river fleet which has been sold to be taken to Puget Sound, has been drydocked for repairs.

Steamer Painting, etc., Portland, Ore.—The steamer West Keats, of the Columbia-Pacific Shipping Company, has been drydocked for cleaning and painting.

Docking and Repairs, Baltimore, Md.—The United States Coast Guard cutter Comanche has been taken to the yard of the Maryland Drydock Company for docking and repairs.

Complete Overhauling, Savannah, Ga.—The Savannah liner City of Montgomery has been taken to the wharf of Rourke's Iron Works for extensive repairs and overhauling.

Pump Repairs, Jacksonville, Fla.—The steamer Allaguash, of the Foreign Transport & Mercantile Line, has been taken to Jacksonville for repairs to her circulation pump.

Cleaning and Painting, Portland, Ore.—The schooner North Bend has been lifted on drydock at Portland for cleaning and painting. The Oregon Pine is also on the drydock.

Propeller Installation, San Francisco, Cal.—The new Electra Line steamer Cuba went to the Bethlehem Shipbuilding Corporation's yard for the installation of a new propeller blade.

Conversion Work, Whitehaven, Md.—After having been a Chesapeake Bay freighter for 51 years, the schooner Eugie has been taken to the Whitehaven shipyard, Maryland, to be rebuilt.

Tanker Drydocked, Chester, Pa.—The Atlantic Refining Company's tanker Frances E. Powell has been drydocked at the Sun Shipbuilding and Drydock Company's yard, Chester, for miscellaneous repairs.

Completion of Repairs, Los Angeles, Cal.—The Los Angeles Shipyard has completed repairs on the Shipping Board tanker Hoven, chartered to Walker & Daly, the damage cost being approximately \$30,000.

Vessel Repairs, Los Angeles, Cal.—The tank steamer Hampton Roads, operated by Struthers & Barry, has been placed on the ways of the Los Angeles shipyard for repairs due to recent collision.

Bid Openings, San Francisco, Cal.—Bids have been taken for repairs and other work to the Pacific Mail steamers San Juan and Ecuador, and also for repairs to the French liner Montana, recently damaged in collision.

Spud Gallows Bids, Jacksonville, Fla.—The W. G. Brennan Company, Jacksonville, Fla., was low bidder at \$1,200 for a spud gallows frame for the dredge Mallory, of the U. S. Engineer Office, Jacksonville, Fla.

Low Bidder, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation was low bidder for covering miscellaneous repairs on the Panama steamer Ida of W. L. Comyn & Company, at recent bid openings.

Flat Boats Proposed, Cincinnati, O.—The United States Engineer Office, Cincinnati, Ohio, has under consideration the construction of three steel needle flat boats for use on the Ohio River dams. The cost will be about \$2,000 each.

Cargo Carrier Reconditioning, San Francisco, Cal.—The General Engineering Corporation of San Francisco has received the contract for the reconditioning of the Shipping Board cargo carrier Liberty Land, at a price of \$14,110.

Contract Awarded, Tacoma, Wash.—The Todd Dry Dock & Construction Company, Tacoma, Washington, has been awarded a contract for six steel barges for the U. S. Engineer Office, at Portland, Ore. It is understood that the total price is \$114,900.

Survey, etc., Quincy, Mass.—The steamer Mars, which recently grounded while leaving Boston on a trip to Norfolk, has been to the Fore River Shipbuilding Company's plant in Quincy for survey and repairs. It was found that some plates were damaged.

Fifteen-Barge Job, Sturgis, Ky.—The West Kentucky Coal Company of Sturgis, Ky., has awarded the contract for lumber for fifteen new wooden barges to the Marsh & Truman Lumber Company, Chicago. The Coal Company will build the barges at its plant at Paducah, Ky.

Boats Under Construction, Fort Myers, Fla.—A speed-pleasure boat, under construction at the Williams ways in East Fort Myers, and a concrete boathouse, being built by Contractor D. W. Ireland, west of Fort Myers, are being constructed for Med D. Kelum, of Fort Myers.

Shipyard Activities, San Francisco, Cal.—The Bethlehem Shipbuilding Corporation has been awarded the work of installing a new fore-foot on the Standard Oil tanker Richmond, and also general repairs for damage sustained by fire on the American-Hawaiian fleet freighter American.

Steamers Reconditioned, New York, N. Y.—According to recent announcement, the American liner Manchuria and the Red Star liners Kroonland and Finland will be reconditioned in New York for the new service of the International Mercantile Marine Company to Pacific Coast ports.

Voyage Repairs, San Francisco, Cal.—The following were the bids received for voyage repairs to the Pacific Mail liner President Pierce: United Engineering Company, \$5,179; Bethlehem Shipbuilding Corporation, \$5,597; General Engineering and Drydock Company, \$6,149, and the Moore Drydock Company, \$6,695.

Small Craft for U. S. Engineers.—The United States Engineer Office, New Orleans, La., has awarded the contract for furnishing and delivering one inspection boat, complete, to Duvie Sons, at a price of \$2,963. It is reported from Wilmington, N. C., that the Engineer Office proposes to purchase one motor dredge tender.

Navy Cruiser Launched, Philadelphia, Pa.—The Marblehead, the fourth of five light cruisers built or now building at the yards of the Wm. Cramp & Sons Ship and Engine Building Company for the United States Navy, was launched from the ways of the company on Tuesday, the results of which proved satisfactory in every way.

Reconditioning Bids.—The General Engineering and Drydock Company, San Francisco, Cal., was

low bidder for reconditioning the Shipping Board steamer Liberty Land for spot service, when tenders were received, recently. The following were the proposals: General Engineering, \$14,110; Moore Drydock Co., \$24,227; Bethlehem Ship. Co., \$24,814.

Low Bidder, Tanker Repairs.—The Crowley Shipyard, San Francisco, Cal., was low bidder at the opening of tenders for extensive general repairs to the Shipping Board tanker Betterton. The prices were: Crowley Shipyard, \$4,200; General Engineering, \$7,490; Bethlehem Corp., \$7,680; Moore Drydock Co., \$7,797; United Engineering, \$8,150.

Bids for Repairs, West Coast.—At the opening of bids, recently for reconditioning the United States Shipping Board steamer West Montop for spot service, the Hanlon Shipyards, of Oakland, Cal., submitted the lowest tender. The following prices were submitted: Hanlon, \$15,620; General Engineering, \$17,252; Bethlehem, \$17,467; Moore Drydock Co., \$19,935.

Contract Awarded, San Francisco, Cal.—The contract for general repair work on the Shipping Board steamer West Prospect has been awarded to the Crowley Shipbuilding Company. The bids on the vessel were as follows: Crowley Shipyard, \$1,600; Main Iron Works, \$1,709; Theodore Smith, \$1,882; Bethlehem Shipbuilding Corporation, \$1,993; General Engineering Company, \$2,095.

Conversion Job, Brooklyn, N. Y.—The contract for converting the 3-masted commercial schooner Priscilla Alden into a motor yacht has been awarded by the firm of Tams and King to the Tebo Yacht & Basin Company, of the Todd Shipyards Corporation. The vessel is to be equipped with Frisco Standard engines and it is understood the contract will cost close to \$70,000.

Bids for Boiler and Fittings.—The Charleston Dry Dock & Machine Company, of Charleston, S. C., with a price of \$8,764, was low bidder for furnishing one steam boiler, with fixtures, stack, etc., for the U. S. dredge Upatoi, at the recent opening of proposals by the U. S. Engineer Office, Mobile, Ala. Two bids were submitted, the other being a price of \$13,820 by the Federal Shipbuilding Company, both tenders having been rejected.

Tug Launching, Los Angeles, Cal.—The new tug D. M. Renton, a sister-ship of the recently completed David P. Fleming, has been launched on the west coast. The vessel is 85 feet long, has a 250-horsepower Winton Diesel engine, and cost \$75,000. She will have a speed of 12 knots. The tug is being built by the William Muller shipyards, which has orders for three more such tugs for the Wilmington Transportation Company.

Shipyard Activities, West Coast.—The steamer Floridian has been placed on the drydock at the Bethlehem Shipbuilding Corporation's plant, San Francisco, for an overhauling and repainting. The Union Line motorship Huraki has gone on the drydock of the same company for propeller repairs. The freighter Steel Seafarer has been at the Moore yard, Oakland, for the replacing of three plates on the port side of the vessel.

Propeller Wheels, Philadelphia, Pa.—According to recent announcement a new set of propeller blades have been ordered from the William Cramp & Son Shipyards, at Philadelphia, for the United States Line steamship George Washington. The new wheels for the George Washington will be 21 feet 3 inches in diameter (the steamer now making a speed of 18½ knots), while those of the Leviathan, also cast by the Cramp Company, are 16 feet 6 inches.

Contract for Derrick Boat Hulls Awarded.—The Chief of Engineers, Washington, D. C., has awarded to the Dravo Contracting Company, Pittsburgh, Pa., a contract for nine steel derrick boat hulls, at a total price of \$130,140, delivery to be in 270 days. Six of these hulls are for the Louisville district of the Ohio River, two are for the Engineer Office at Rock Island, Ill., and the ninth is for use on the Green River, Ky.

Tanker Launched, San Francisco, Cal.—The Alaska Standard, building for the Standard Oil Company for use in Alaska waters, was recently launched from the ways of the Bethlehem Shipbuilding Corporation. The vessel is 210 feet in length, 40 feet beam and 16.6 feet deep. She will be equipped with two 400 horsepower Diesel engines, have a speed of about 12 knots and a carrying capacity of 12,000 barrels.

Diesel Installation on Admiral Line Ships.—The Admiral Line has called for bids on the transfer of Diesel engines from the wooden motorship Benowa to the steel auxiliary schooner Moonlite. Upon the installation of the engine the Moonlite will be placed in the coastwise trade. It has been stated that the conversion of the Moonlite is the first step to re-engine four ships of the same class with engines from four vessels of the Benowa type.

Contract for Dredge Awarded, Louisville, Ky.—The E. T. Slider Company, Fulton and Campbell streets, Louisville, Ky., has awarded the contract for a steel dredge boat hull and cabin to the Midland Barge Company, of Pittsburgh, Pa. The hull is to have a length of 176 feet, beam 50 feet, and depth 6 feet. The same company, which deals in sand and gravel, has awarded a contract for six heavy type steel barges to the Howard Shipyards, Jeffersonville, Ind.

Repairs, San Francisco.—The General Engineering and Dry Dock Company was low bidder on two reconditioning jobs, at recent tender openings. The work of reconditioning the West Mingo for spot service showed a bid of \$21,540 from the General Engineering Company, the other prices submitted being: Moore Drydock Company, \$23,644.55, and Bethlehem Shipbuilding Corporation, \$24,430. The company bid \$4,294 for general repairs on the Government vessel, General Frank M. Cox, and they were awarded the contract.

Vessel Repairs, West Coast.—At the opening of tenders for the carrying out of repairs to collision damage on the French Line steamer Montana, the Moore Drydock Company was low bidder. The work consists of repairs to her bow, covering the renewal of five plates, four plates to be faired up, fifteen new frames to be installed and new anchor stocks. The bids were as follows: Moore Drydock Company, \$22,495, 14 days; Bethlehem Shipbuilding Corp., \$25,960, 13 days; United Engineering Works, \$26,450, 16 days; General Engineering Co., \$27,000, 18 days.

Vessel Repairs, Brooklyn, N. Y.—The Robins Drydock & Repair Company, of the Todd Shipyards Corporation, Brooklyn, N. Y., was awarded the contract for repairing collision damage to the steamship West Arrow, at the opening of bids by the Shipping Board, at 10 A. M., on October 4, at 45 Broad Street, Boston, Mass. Six companies submitted proposals as follows: Robins, \$47,970, 38 days; Morse, \$47,955, 40 days; Bethlehem, \$48,750, 43 days; Atlantic Works, \$49,789, 39 days; W. & A. Fletcher, \$50,000, 40 days; Newport News, \$52,940, 32 days.

Repairs, Los Angeles, Cal.—According to information from Los Angeles, Cal., damage to the steamer Virginia Olson, which collided with the steamer Claremont in the Los Angeles Harbor recently, is estimated at more than \$30,000. It is said that oil tanks and bulkheads amidships must be removed before work can proceed on replacement of the damaged hull. It has also been announced that the steamers Meriden and Olympic have been ordered reconditioned with wider hatches, changed decks and other improvements. The work on the Meriden will cost \$45,000, with extras mounting to perhaps \$60,000. It has been stated that the vessels, which are already able to unload in three and one-half days, will be able to cut that time almost in half when improved.

SHIPYARDS AND DRY DOCKS

New Drydock, New Orleans, La.—The Johnson Iron Works, New Orleans, La., have a new drydock, 416 feet 3 inches long and 75 feet between wings, with a lifting capacity of 7,000 tons.

Drydock, Chester, Pa.—The Sun Shipbuilding Company has been negotiating for the purchase of one of the 10,000-ton drydocks owned by the Shipping Board, which is to be towed to Philadelphia. President Pew has admitted the company has taken the drydock under a lease with an option of purchase.

Union Shipbuilding Company Reorganizes Repair Department.—Word comes from the Union Shipbuilding Company, Baltimore, Md., of the company's reorganization of their Repair Department for the purpose of actively engaging in the repairing and drydocking of vessels up to 420 feet in length and 5,000 tons displacement while light.

Cannery Buys Shipyards.—Word comes from Seattle that the wooden shipbuilding plant at Houghton Lake, Washington, originally known as the Anderson Yard, has been purchased by the Alaska Consolidated Canneries from the Lake Union Drydock and Machine Works. The new owners will continue the yard in commercial business.

Shipping Board Dry Docks Leased.—Besides the leasing of one of the 10,000-ton drydocks of the Shipping Board to the Sun Shipbuilding and Drydock Company, Chester, Pa., the Shipping Board has also leased two others of the same type to the following: one dock, located at Weehawken, N. J., to the Todd Drydock & Shipbuilding Company, of New York, and the other dock, which is at Newport, R. I., to the Alderton Dock Yard, Ltd., of Brooklyn.

Drydock Purchased, Alameda, Cal.—The United States Shipping Board has sold a 16,000-ton floating drydock to the General Engineering and Drydock Company, the concern owning and operating the former Alameda Bethlehem plant. The General Engineering Company will tow the huge craft from the Atlantic to the Pacific, the drydock being the first one ever towed from the Atlantic to the Pacific Coast. The trip will require forty days or more and two Red Stack tugs will leave San Francisco bay to undertake the tow as soon as word is received from President George Armes, of the yard, that the preliminary details have been completed.

PORT IMPROVEMENTS

Pier and Derrick Plant, Owensboro, Ky.—The River Sand & Gravel Company plans to build a concrete pier with derrick.

Clam Shell Buckets, Pittsburgh, Pa.—U. S. Engineer, Pittsburgh, plans to purchase two 2-yard clam shell buckets.

Buckets, Mobile, Ala.—U. S. Engineer, Mobile, plans to purchase one 3-side orange peel bucket and one 3-yard clam shell bucket.

Canals, Fair Oaks, Cal.—Beach & Cox plan 4 mile canals, 11 feet wide at top, 4 feet at bottom, 2 feet deep; 2 centrifugal pumps, 31.1 sec. foot capacity, 12-foot lift.

Dock, Creighton, Pa.—Crucible Fuel Company, Oliver Building, Pittsburgh, plans new pile and timber dock at Creighton on the Allegheny River; cost to exceed \$25,000.

Port Work, Los Angeles, Cal.—The Harbor Commission of Los Angeles has awarded the contract for pier work, etc., at Wilmington, to the Griffith Company for \$21,221.80.

Levee, Kaufman, Tex.—Kaufman County Levee Improvement District 4 held an election on October 13 for the purpose of voting on \$175,000 bonds for improvements, alterations and repairs.

Dock, Mingo Junction, O.—Carnegie Steel Company, Carnegie Building, Pittsburgh, Pa., plans coke unloading dock, stationary crane on concrete caisson foundation, mooring piles, etc., here, \$50,000.

Breakwater, Francis Harbor, N. S.—Bids will be received by R. C. Desrochers, secretary, Department of Public Works, Ottawa, Ont., for a 301-foot concrete breakwater, 20 feet wide, Francis Harbor, at \$30,000.

Breakwater, Port Lorne, N. S.—R. C. Desrochers, secretary, Department of Public Works, Ottawa, received sealed proposals on October 22 for 50-foot extension to concrete breakwater, 45 feet wide, here, \$27,000.

Crane, Tacoma, Wash.—Port of Tacoma, National Bank of Tacoma Building, is in the market for a 90-foot electric crane with track and necessary operating equipment. \$50,000. Address G. M. Osgood, chief engineer.

Grain Elevator, Port Arthur, Tex.—Kansas City Southern Railroad, 11th and Wyandotte streets, Kansas City, Mo., is taking bids for a concrete grain elevator, 600,000-700,000 bushels, here, \$25,000. C. E. Johnson, c/o owner, engineer.

Dredging, Harlingen, Tex.—Sealed proposals were received by C. Brown, secretary, Cameron Water Improvement District 1, on October 22, for dredging 8-mile canal, 60,000 cubic yards excavation, etc., in Cameron County. \$25,000. A. Tamm, Harlingen, engineer.

Pontoon, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Court Building, on October 25, for a reinforced-concrete pontoon for the Ferry Landing at the foot of Canal street. J. H. Walsh, general manager. Requisition E. D. 14101.

Waterway Opened, Lake Okeechobee, Fla.—Lake Okeechobee, the second largest body of fresh water in the United States, has been linked with the Atlantic Ocean, sixty-five miles away. The inlet, which extends from the lake to the ocean, was formally opened with fitting exercises and will be navigable to yachts and freighters drawing not more than ten feet of water.

Wall and Dike, etc., Shreveport, La.—Sealed proposals were received on October 23 by S. G. Wolf, secretary-treasurer, for 1,000 feet of sheet pile toe wall, 24 feet deep, 2,200 feet of pile dike 55 feet deep, willow fascine or plank mattress under dike 100 by 2,200 feet, 20,000 cubic yards of grading and 25,000 square feet of creosote pavement. Alternate bids on long crib filled with brush anchored to piling. C. E. Smith, Railway Exchange, St. Louis, Mo., engineer.

Erection of Ferry Landing, New Orleans, La.—The Board of Commissioners of the Port of New Orleans will receive sealed proposals at their office, Suite 200, New Court Building, until 3 P. M., November 15, 1923, for furnishing and erecting the Ferry Landing at the foot of Canal street, New Orleans, Louisiana, approximately 175 tons of structural steel for a double deck, double drive ferry bridge, and 25 tons of bridge operation machinery. J. H. Walsh, general manager. Requisition E. D. 14122.

Shed Construction, Portland, Ore.—The Commission of Public Docks, Portland, has awarded a contract to O. R. Wayman for the construction of an addition to the main shed on the quay dock at terminal No. 1, which is to extend along the west side of the shed for a width of 47 feet and length of 900 feet, and has also approved an agreement with the Eastern & Western Lumber Company for the joint dredging and maintenance of a slip between the mill property and the north end of terminal No. 1, where Pier C is to be erected. The Commission has adopted the 1924 budget that totals \$1,157,770. Dredging of the new slip is to be undertaken by the Port or Portland and material removed will be used to fill part of the property, which was recently joined to the terminal holdings through purchase. Authority has been granted G. B. Hegardt, chief engineer, to advertise for the removal of part of the old piling on the river side of the land so dredging would be expedited.

GOVERNMENT WORK

Dredging, Providence, R. I.—Sealed proposals were received on October 17 at the office of the U. S. Engineer, for dredging 373,000 cubic yards in Providence Harbor.

Fill, Philadelphia, Pa.—Specification 4919—Bureau of Yards & Docks, Navy Department, Washington, D. C., plans filling back channel at Naval Hospital, here.

Bids Rejected, Pearl Harbor, H. T.—Specification 4827—The Bureau of Yards & Docks, Navy Department, Washington, D. C., rejected bids for fire protection system at Naval Operating Base, here.

Lumber, Paris Island, S. C.—Port Quartermaster, Marine Barracks, awarded the contract for 100,000 feet of lumber, various sizes, to Montgomery & Company, 10 South 15th Street, Richmond, Va. Engineers' estimate, \$5,300.

Contract Awarded, Jacksonville, Fla.—U. S. Engineer, Jacksonville, awarded the contract for 25 pontoon catamarans for the dredge Barnard to Novelty Steam Boiler Works, 917 South Howard Street, Baltimore, Md., \$24,350.

Piling, Owensboro, Ky.—U. S. Engineer, P. O. Box 72, Louisville, plans to purchase 500 piles, 25 feet long, and 1,000 piles, 30 feet long, not less than 12-inch butt and 8-inch tip. F. O. B. Owensboro, for Dam 46, Ohio River.

Dredging, Oakland, Cal.—U. S. Engineer, P. O. Box 72, plans to purchase 500 pieces of 12-foot, 500 pieces of 16-foot, 1,200 pieces of 20-foot and 400 pieces of 22-foot (all 2 by 12 inches) No. 1 common yellow pine f. o. b. Addison.

Dredging, Elizabeth River, Va.—Sealed proposals were received by the U. S. Engineer Office, Norfolk, Va., on October 30, for dredging in the Eastern Branch of Elizabeth River, Norfolk Harbor, Va. Further information on application.

Lumber, Rock Island, Ill.—The contract for furnishing 237,000 feet of Douglas fir for use at Le Claire Canal Lock, etc., has been awarded by the U. S. Engineer Office to G. T. Mickie Lumber Company, 30 North La Salle Street, Chicago, at \$5.037.

Dredging, Boston, Mass.—U. S. Engineer, Custom House, awarded the contract for dredging and disposing of 600,000 cubic yards of material from Beverly Harbor, to J. S. Packard Dredging Company, Turks Head Building, Providence, R. I. \$24.691.

Piling, Cincinnati, Ohio.—U. S. Engineer, Cincinnati, awarded the contract for furnishing sixty 30-foot taper piles, one hundred forty-six 40-foot and sixty 35-foot steel sheet piles for Dams 34, 36 and 38, to Bethlehem Steel Company, Cincinnati, at \$2.94 a hundredweight.

Discharge pontoons, Rock Island, Ill.—Sealed proposals were received by the U. S. Engineer Office, Rock Island, on October 17, for the construction and delivery of twenty 38-foot by 14-foot by 3-foot steel discharge pontoons. Further information on application.

Dredge Pump, etc., New Orleans, La.—U. S. Engineer Office, 329 Customhouse, New Orleans, La., will receive sealed proposals until 9 A. M., November 2, 1923, for constructing and delivering one 24-inch dredge pump and suction mouthpiece. Further information on application.

Breakwater Construction, Hilo Harbor, H. T.—Sealed proposals were received by the U. S. Engineer Office, Honolulu, T. H., on October 15, for breakwater construction, Hilo Harbor, T. H. Further information on application here or to U. S. Engineer Office, 401 Customhouse, San Francisco, Cal.

Repairs, Philadelphia, Pa.—The contract for repairs to substructure and deck portions of Piers 97, 98 and 99, Greenwich Point, Delaware River, Philadelphia, has been awarded by the U. S. Shipping Board, c/o J. M. Hoffman, Head, Division of Docks and Wharves, 1907 Navy Building, Washington, D. C., to E. Fay & Son, 2 South Mole street, at \$154,800.

NEW INCORPORATIONS

The Lake & Ocean Company, of Buffalo, capital \$65,000, chartered under New York laws, to operate steamers. Incorporators: W. F. Delaney and L. B. Olshei.

Coal Ports Transportation Corporation of Manhattan, capital \$10,000, chartered at Albany, to engage in navigation. Incorporators: J. A. Sheridan, A. E. Flanders and H. V. Boyle.

Davis Transportation Lines, Inc., capital \$350,000, incorporated in Delaware to own and operate steamships. Incorporators: Robert K. Thistle, Harry C. Hand and George V. Reilly, of New York.

Philadelphia & New York Transportation Company, capital \$5,000, chartered under Delaware laws to engage in the transportation of freight. Incorporators: C. B. Outter, S. B. Mackey and L. C. Christy.

Marmack Transportation Company, capital \$1,500,000, chartered under Delaware laws, to operate vessels. Incorporators: James A. McDavid, Harry F. Martin, Clayton C. Wright and Stanley Safreed, of Pittsburgh.

The Inland Water Line: principal place of business, Jacksonville; capital stock, \$250,000; limit of indebtedness, \$1,500,000. Corporate existence 99 years. General nature of business: To own, control and acquire by lease, purchase, construct, or otherwise, steamships, boats, barges and vessels of all kinds or interests therein, and to operate the same for transportation line for passengers and freight of all kinds, etc. Officers and directors: William H. Furrow, president; Damon G. Yerkes, vice-president; J. Henry Blount, secretary and treasurer. Letters patent issued, September 25, 1923.

Florida Canal and Transportation Company; principal place of business, Jacksonville; capital stock, \$3,000,000; limit of indebtedness, \$10,000,000. Perpetual corporate existence. General nature of business: To acquire, have, hold, use, enjoy, exercise and operate the canals, rights of ways, waterways, and rights and privileges, franchises, immunities, machines, houses, implements, appendages, appurtenances and properties being, pertaining to or used in connection with all or any of the canals and waterways which are or were of Florida Coast Line Canal and Transportation Company, a corporation created and existing under the laws of the state of Florida, and having been conveyed or mortgaged by the Florida Coast Line Canal and Transportation Company to the Rhode Island Hospital Trust Company as trustees, etc. Letters patent issued September 11, 1923.

SHIPPING DEVELOPMENTS

Megee Brothers.—Ralph D. Megee, of Megee Brothers, has purchased the British schooner Montclair. She was sold at a United States Marshal's sale in Camden, recently.

Mallory Transport Lines.—Announcement has been made by Rogers & Webb, Boston agents for the Mallory Transport Lines, of a new steamship service between Boston and South African ports, which opened last month.

Cunard Line.—Triangular steamer service between London, Boston and Portland, which was maintained last winter by the Cunard Line, will be re-established at the close of navigation in the St. Lawrence river this winter, according to information from Boston. The Vardalia will leave London the first week in December for Boston.

Construction Materials Company.—The Construction Materials Company of Chicago has purchased two lake type steel cargo vessels from the Shipping Board. The ships are the Lake Clear, of 2,875 deadweight tons, and the Lake Weir, of 2,875 deadweight tons. The purchaser agreed to install Diesel engines in the Lake Weir by the terms of the sale.

United American Lines.—According to announcement by Christian J. Beck, vice-president in charge of freight traffic of the United American Lines, the company will have a fortnightly eastbound intercoastal service calling at Boston and Philadelphia. This service is said to be in connection with the weekly sailings between New York and Baltimore and West coast ports maintained jointly with Houlder, Weir and Boyd.

San Juan Transportation Company.—The San Juan Transportation Company, of Bellingham, Washington, has purchased the steamer Astorian, which formerly operated on the run between Portland and Astoria and which has been out of commission for about three years. This ship is an oil burner with two stacks and is of a type similar to many vessels operated on Puget Sound, being 145 feet long and approximately 100 tons burden.

MARINE SOCIETIES

AMERICA

American Society of Naval Engineers

Navy Department, Washington, D. C.
Secretary-Treasurer—Commander S. M. Robinson,
U. S. N., Bureau of Engineering, Navy Department, Washington, D. C.

Society of Naval Architects and Marine Engineers

29 West 39th Street, New York
Secretary and Treasurer—Daniel H. Cox.

National Association of Engine and Boat Manufacturers

29 West 39th Street, New York City
Secretary—R. R. A. Hand.

United States Naval Institute

Naval Academy, Annapolis, Md.
Secretary and Treasurer—Commander H. K. Hewitt, U. S. N.

American Marine Association

MARINE ENGINEERING AND SHIPPING AGE is a member of the Associated Business Papers, Inc. (A. B. P.), and the Audit Bureau of Circulation (A. B. C.)

Request for change of address should reach us two weeks before the date of the issue with which it is to go into effect. It is difficult, and often impossible, to supply back numbers to replace those undelivered through failure to send advance notice. In sending us change of address, please be sure to send us your old address as well as the new one.

The Marine Congress

FOR the first time since the movement to encourage and promote the growth of the American merchant marine was initiated, a body of men, representing the general business interests of the country, has met together for the consideration of this great national problem, and is effecting a permanent organization to carry on the work and to co-ordinate and concentrate the various forces tending towards its successful prosecution.

The deliberations of the Marine Congress, composed as it was of representatives of a hundred different and widely varying commercial bodies and organizations, represent the result of matured thought and careful analysis of ways and means on the part, not only of those directly interested in shipping, but of merchants, manufacturers, farmers—in short of men representing the commercial interests of the entire United States.

That the country is awake to the necessity of a merchant fleet and to the very direct bearing which the possession of this fleet has upon the future prosperity of its citizens is becoming daily more apparent. There is no question but that the problem of placing American ships on the high seas and keeping them there will largely occupy the attention of the approaching session of Congress, and the submission to that body of a definite policy to attain this end will go far toward making effective action possible.

So far as can be judged by the daily press, a majority of the people have come to a realization of the fact that an adequate merchant marine is necessary, if the country is to retain any control of its export business, possess an efficient navy and in every other respect to hold its position as a first class

power among the nations of the world. It is equally apparent that a majority of the people are of the opinion that this merchant marine should be privately owned and operated.

It is important that senators and representatives should come to a realization of these facts. It is also important that they should understand clearly that the body submitting these facts for their renewed consideration is a national body and that steps are being taken to make it a permanent one.

The Shipbuilding Outlook

THERE is no disguising the fact that the "Naval Holiday," beneficial as its results may be to the world in general (and we are by no means certain that it is an "unmixed blessing," even in this particular) has given a staggering blow to the shipbuilding industry. The large shipyards have to a great extent attained their present size and perfection of equipment as a result of the demand for battleships, and for many years it has been the foundation of large naval work which has made the building of others and less important vessels economically possible. Now that this foundation is to be removed, what are the possibilities of continued operation for these large and costly "private navy yards"?

A large shipyard includes in its operation many mechanical trades or lines of work, and the individual shops of which it is comprised can each produce articles of general value. Such a plant, however, if properly laid out for economical ship production, does not lend itself readily to manufacturing processes, and to fit it for successful competition in such fields considerable modification is necessary. It is idle to suppose that an ordinary shipyard structural shop can, in the long run, successfully compete with a modern bridge shop, nor that a shipyard machine shop and boiler shop can economically produce locomotives. A shipbuilding company can, of course, alter its shops to produce successfully almost any structure or machine, but it then ceases to be a shipyard, although it still has the enormous investment in shipways, cranes and heavy machinery hanging on its neck and serving only to keep up maintenance and overhead expenses.

Mr. Powell, in his speech at the annual dinner of the Society of Naval Architects and Marine Engineers last month, stated this condition clearly and frankly, and his suggestions as to how it may best be met appear to us as sensible and worthy of the careful consideration of everyone having the welfare of the shipbuilding industry at heart.

Discouraging as the outlook appears in the aggregate, it is by no means, as some pessimists would have us believe, as

bad as possible. Shipbuilding in this country is a very long way from being dead. Many vessels are under construction, and it is altogether probable that a larger number will be required in the future, but the volume of work, as represented by the amount of money expended, will probably not equal that of the era of battleship construction for many years to come.

Mr. Powell suggests that, from every point of view, it is better to meet the future demand for ships with a relatively small number of yards, working efficiently and at something like normal capacity, than with a large number, each working at a fraction of the output necessary to carry its overhead and all facing eventual and inevitable disaster.

Hard as this suggestion may be in its accomplishment, the logic of it is unquestionable. So far as can now be seen, the eventual prosperity of American shipyards can be assured only by a process of elimination and combination whereby such a number of efficient yards will be kept in operation as bears a reasonable relation to the total amount of work to be turned out.

Shipping Board Economies

THE record of the various economies already effected or being put in practice by the operating department of the Emergency Fleet Corporation reflects credit upon those responsible for the operation and maintenance of the Shipping Board's fleet.

With the detail methods of operating the government vessels we are not familiar, but the steps taken in this connection to prevent waste and eliminate unnecessary expense appear entirely reasonable and, judging from the figures given, are producing satisfactory results.

In one particular, however, we are inclined to take issue as to the entire wisdom of the policy being followed. This is in relation to the care of laid-up vessels. Fundamentally, the greatest saving possible would result from the elimination of all vessels (and there is a very considerable number of them) which have no commercial value, thus, at one stroke, cutting out a large part of the present expense of upkeep, as well as removing a fleet of ships, which, while it will not in all human probability ever be commercially employed, is, nevertheless, a menace to the satisfactory settlement of the country's shipping problem.

We realize quite well that the sale or other disposal of laid-up vessels is a matter quite outside the jurisdiction of the operating department, and mention it only to indicate our belief that a major and not a minor operation is needed to satisfactorily solve the laid-up ship problem.

Turning then to the methods pursued in caring for these vessels, we believe that everyone will agree as to the wisdom of fleet concentration with the consequent reduction of caretaking personnel, as well as the elimination of wharfage charges. The physical care of the ships, however, may easily be neglected to the point where serious deterioration sets in, and we fear that this point has been reached, or will be shortly, by practically all of the laid-up ships. Although the total of the laid-up fleet personnel appears at first glance a large one when the number of ships to be cared for is taken into consideration the number of men available per

ship becomes entirely inadequate to properly handle the situation. By eliminating "dead" tonnage and concentrating upon potentially valuable vessels, effective upkeep might be maintained without a greater total expense than at present. We believe, however, that the more valuable ships should be cleaned, painted and otherwise thoroughly preserved at the earliest practicable date. With this properly accomplished, a laid-up crew of very moderate size can render all the attention necessary for a long time to come. On the other hand, the ships are in a condition where a year or two more at the present rate of depreciation will render them useless or at least in a condition requiring extensive repairs to fit them for service.

Weakness of the Shipping Board

IN an address on the Shipping Board at the Marine Congress dinner recently given in New York, Commissioner Haney made, in substance, the following rather interesting and unique statement: "When I was asked to become a member of the Board, I hesitated considerably before accepting as I felt that I had but little knowledge of shipping affairs. However, my friends advised me to accept as I 'certainly knew as much about it as any of those other fellows.'"

We have no doubt as to the ability and personal integrity of Mr. Haney, nor indeed of that of the other members of the Board; but does not the above statement go far to explain the apparent lack of cohesion shown by the actions of the Shipping Board, its failure to work in sympathy with private owners and operators and, finally, the enormous expense involved in its activities?

It seems to us that it is about time for this very important body to be composed of men whose lives have been devoted to the work which the Board was created to oversee and foster, and that the fact that a man is considered "to know as much as those other fellows" is not a sufficient recommendation for membership.

Even were the Board made up entirely of men peculiarly fitted for the work, the possibility of effective functioning as an executive body is remote. In an advisory capacity, a committee of seven may be desirable, but for prompt and efficient executive action a much smaller body is essential; and one good man, if he could be found, would produce more and better results than any committee could possibly accomplish.

The present attitude of the administration apparently makes inevitable the continuation of the Board's activities for some time to come. Assuming this to be the fact, cannot steps be taken by the forthcoming Congress to reduce the Board to a workable size and restrict its members to those having expert knowledge of the questions which they are called upon to decide?

Work of great value has been accomplished in certain of the departments comprised in the Board's activities. Its members should have sufficiently expert knowledge to appreciate the importance of such constructive results as have been attained and to so direct its line of action in the future that it may be a help and not a hindrance to the development of the merchant marine.

Secretary Hoover Declares Our Merchant Marine Indispensable for Protecting Our Foreign Trade

Address of the Secretary of Commerce at the Marine Congress Banquet Shows How Double Taxation of American Merchants Abroad Is Handicapping Growth of Our Overseas Shipping

AS the principal speaker at the Marine Congress banquet held at the Waldorf-Astoria Hotel, New York, on Thursday evening, November 8, under the auspices of the American Marine Association, Herbert Hoover, Secretary of Commerce, reiterated the facts so well known to all ship-minded American citizens that we must have our own ships for the protection of our foreign trade, for the expansion of our exports and for our national defense but he also pointed out one disastrous handicap to the growth of our merchant marine which is generally overlooked but which is capable of remedy and that is the double taxation of our merchants abroad. Secretary Hoover's address was as follows:

It is simply a truism to say that we must have an American merchant overseas marine. Entirely apart from the fine sentiment and national pride of a great trading nation in keeping its flag upon the seas, we must have our own ships for the protection of our foreign trade; we must have ships if we would expand our exports on sound lines and we must have them as an auxiliary to our national defense.

OUR STANDARDS OF LIVING DEPEND ON INTERNATIONAL TRADE

It seems worth repeating at times that our international trade is one of the very foundations of our standards of living; that our whole fabric of living and comfort are dependent upon the import of commodities which we do not and can not ourselves produce—tin, rubber, coffee, sugar and a score of others; further, in the main the amount of these commodities we can import will depend upon the volume we export. Moreover we need a constant expansion of our export markets to give stability to our internal production by a wider range of customers.

If we are to have secure export markets we must have some sound proportion of American controlled shipping to assure us against combinations in rates which would prejudice our goods in competitive markets. Nor have our merchants been without the experience of finding that the transport of our goods in foreign bottoms has been taken advantage of by our competitors to learn the details of our trade connections.

The facility of the world in creating combinations in restraint of trade has been growing by leaps and bounds since the war and while we, as a nation, endeavor to curb these activities within our borders, there has naturally been no curbing of these activities abroad when they affect American interests. Today there are many commodities upon which we are dependent by import from foreign lands in which there are combinations in control of price in those foreign lands. Combinations in control of sea rates are the commonest thing in the world shipping fabric. Many of our raw material exports, such as wheat, are sold in the world market in competition with those of other countries and the price level in these cases is the result of competitive streams that flow into these world markets. In wheat the farmer's return is fundamentally the price which he receives at Liverpool less the cost of transportation and handling. Therefore, any increase in shipping rates is in fact a deduction from the price to the farmer. It is just as important to him to be

guaranteed reasonable rates of sea transport as of land freight.

The real security is an American-owned merchant marine. In the long view the expansion of our foreign trade must and will take place in the export of larger proportions of manufactured goods. The primary requisite for such expansion is the assurance of regularity in transportation. Not only do we need regularity of sailings week by week, in order that the manufacturer may be assured in his problems of delivery, but our merchants and manufacturers require to know that when they have established their goods in foreign lands then regular transportation will be assured to them over years to come. They can not be dependent upon hazards of foreign shipowners, allied as these owners are with foreign merchants and competitors.

ADEQUATE TRANSPORTATION UNDER OUR FLAG A NECESSITY

We must have especially regular and positive transportation under our flag on those great trade routes where our commerce can and will expand. Nor can America be dependent for her movement of overseas goods upon the make and break of peace and war in different parts of the world. We have had one gigantic national experience with this already. We must have ships under our own flag, if we are to have security in our vital supplies and exports when other nations go to war with each other. As an auxiliary of our national defense we must have preparedness in transport for soldiers and supplies; we must have a training ground for our sailors, or our Navy itself would be helplessly confined to our own coasts.

In a broad sense the American people are endeavoring to establish a merchant marine that will adequately protect and promote our commerce. The ideal is regular, ferry-like service of boats of the cargo liner type with some passenger capacity traversing the great trade routes of the world and carrying at least 50 percent of our foreign trade. Today, outside of oil, we are carrying less than 20 percent. Some day we will attain such a merchant marine. Our national necessities, the capacity of our people for organization, for mechanical development and enterprise will some day bring it about. In the meantime we have much divided opinion in public mind, in the shipping world and in Congress, as to method. And our shipping world is suffering from great handicaps.

AMERICAN MERCHANTS NEEDED ABROAD

It is not my purpose to review all these handicaps that are so familiar to you but rather to present to you one single phase that has not been so generally considered that is capable of remedy. That is the relationship that American merchants abroad must bear to the success of an American merchant marine. We will never have a real American merchant marine until we have a much larger complement of merchants of our own nationality conducting our commerce in foreign ports. Our raw materials are largely sold at our shores to foreign merchants. They dictate the shipping. Again most of our purchases of raw materials are for delivery at our shores. The foreign merchant again controls

the shipping. If we except oil, most of our manufactured goods for export are dealt with by foreign merchants. How real all this is, is shown by the fact that except oil only about 12 percent of our imports and exports were managed by American merchants abroad.

The situation is just as insecure for our exports as for our shipping. If we would make sure of the continuous flow of goods, we must have the American on the ground distributing to the foreign retailer, securing business by his services as well as his price. Many an American merchant has seen his established trade disappear because he depended upon a foreign merchant not to show patriotism to his own country. This situation has been contributed to by the tendency of some of our manufacturers to regard export as a happy hunting ground in times of domestic depression, to be abandoned in times of domestic demand. We cannot have a merchant marine without an army of American merchants in foreign ports. This is the foundation of our British competitors.

No stable consumption of goods can be built upon such a fabric. And other things being equal, the merchant ships his goods under his own flag, even giving a preference to that flag. Our competitors certainly do so. The lack of growth in our merchant personnel abroad is, I believe, to a large degree the fault of our Government for reasons I will detail later.

Despite our expanding export and import trade, the number of our merchants abroad has decreased in late years and yet if we would have a merchant marine they must be increased. The taxation policies of our Government have been to a considerable degree responsible for this situation.

OUR MERCHANTS ABROAD FORCED TO PAY DOUBLE TAXES

We are asking our people to expatriate themselves in order to sell American goods and manage American ships. Our own Government demands in income and corporation taxes up to 58 percent of the profits of our merchants resident abroad. They also pay taxes to the government where they reside. Thus we demand that they pay double taxes. We are the only nation who does such a thing. With tax burdens even greater than ours, our competitors in the world today have freed their merchants resident abroad from this double taxation. For instance, an American merchant firm in London today must pay British taxes amounting directly or indirectly up to 50 percent of his income. The American Government comes along and claims the same sum or even more. In countries not participants in the war, such as the Argentine, the British merchant pays no taxes to his home government, whereas our merchant must pay his taxes in full.

It is, therefore, felt by many as more economic for Americans to stay at home and sell their goods in the Argentine through a German or a British merchant. Scores of our merchant firms, totally discouraged, have thrown up the sponge.

AMERICAN ENGINEERS FIND FOREIGN MISSIONS UNPROFITABLE

Before the war, there were at least 1,000 American engineers employed at substantial salaries in the territories of our former allies. These men went abroad to install American methods, American machinery and equipment in the production of raw materials, and in transportation. These salaried workers now find themselves subject to two gigantic income taxes and thus their foreign mission is unprofitable. I doubt whether there are 100 of them left in foreign territories today. A vast amount of American machinery and equipment that followed in their wake has dried up.

There is one phase of this matter of vital importance to our farmers. Over 80 percent of our agricultural exports go to Europe. Before the war European merchants bought stocks of wheat and grain during our fall marketing season and thus assisted in financing the crop. They carried stocks

in European warehouses thus relieving our congestion. Today, shortage of finance and credit leads them to buy from day to day and thrusts the burden of carrying the world's seasonal reserves either upon our own farmers or upon our merchants. If our merchant firms were established in Europe, it would be possible for them to give delivery at that end and to establish short credits to their customers—all of which would relieve our farmers. But American merchants are not likely to establish in Europe and to pay two income taxes which might absorb up to 75 percent of their income.

Another case of pertinent order is that on the China coast. Inasmuch as China has no dependable corporation law much Chinese capital is invested in foreign corporations under the management of, or in partnership with, Europeans. As foreign governments exact no home taxation from such corporations or their stockholders the Chinese naturally prefer them. We attempted to remedy this by Congressional authority to establish special American corporations under Federal authority but the restrictions are such that the act has failed its purpose. Three large American managed businesses have gone over to control of our competitors at a real loss to our foreign trade and the great discouragement of our merchants. Similar questions are arising in the Philippines.

DISPERSION OF AMERICAN MERCHANTS ESSENTIAL TO DEVELOPMENT OF OUR SHIPPING

I wish to repeat that, if we are to secure the establishment of a merchant marine, we must secure dispersion of the American merchant and our Government today is one of the most destructive influences in the whole matter. I do not wish to argue the theory that Americans who are engaged abroad in reproductive work should not bear their share of the national burden. I would only point out that other nations have found it is uneconomic to impose this burden upon them, and that we are left in a prejudiced position. Nor am I pleading the cause of the American expatriot, who prefers foreign civilization as a luxury, who is bringing no returns to his country by way of his savings or by way of his expansion of American trade.

These two groups are quite distinct. They can be distinguished in tax measures so as to apply the relief only to incomes earned abroad. One is tied passionately to his country's interests and the expansion of its welfare; America to him is the home he serves in managing her trade. He will yet return with his savings to add to the national wealth, whereas the other is but a pensioner on our national resources. And yet as a nation we penalize the one who brings us service and credit.

Notice to Subscribers

THE annual index of MARINE ENGINEERING AND SHIPPING AGE for the year 1923 will be published separately from the magazine at the end of the year. As the complete index will be useful only to those of our subscribers who have kept a complete file of the magazine for the year, only a sufficient number of copies will be printed to meet the requirements of those who notify us before the end of the year of their desire for a copy.

A copy of the annual index will be mailed without cost to each subscriber whose request for it is received at our New York office on or before January 1.

To Develop Foreign Trade—

Ship and Sail in American Vessels. Money Spent for This Service Should Be Developing Our Own Maritime Resources, Not Those of Our Competitors

By "Old Scotch"

ONCE upon a time a prosperous farmer in the great West, who was supposed by his neighbors to be a good business man, ordered 50 tons of fertilizer from a distant point for the annual requirements of his vast acreage and in due course it was delivered at the railroad station, located five miles from his home. It was early spring-time and there was nothing much to do except to attend to the daily chores. His four horses were largely employed in eating their daily rations of hay and corn, the two hired men attended to the chores night and morning and loafed most of the day. The two farm wagons had not been used much during the latter part of the winter and needed some small repairs and a general greasing up to put them in good working condition. Much to the surprise of the loiterers around the railroad station, this supposedly good business farmer appeared one day and made arrangements with a Scandinavian teamster to haul the fertilizer out to the farm at a rate of three dollars a ton, thereby decreasing his account at the village bank to the tune of one hundred and fifty dollars. In a group of the wise men who always gather around the stove at the village store this conversation took place:

"I see that old man Perkins (for that was his name) has hired Olsen to cart that fertilizer out to his farm and by Heck he paid him three dollars a ton for doing it. His own horses are eating their heads off and the two hired men will soon want patches on their pants, and they won't be sewed on their knees either."

"Yes," said the second wise man, "he allowed to me that it wouldn't pay him to haul it himself as his two wagons needed about fifteen dollars' worth of repairs, and anyway it was getting too near planting time to bother with doing his own hauling."

"Well," said the storekeeper, the usual arbitrator in all such discussions, "Perkins better watch out as I've seen the sheriff put a red flag on better farms than his where they've been run by just such bum management as that."

Suppose this village store jury, composed, as the thousands of them are, of good, hard working, common-sense taxpayers who go to make up a great part of the American public, should cast their critical eyes and sound logic on the way Uncle Sam treats his merchant marine, don't you suppose they would find many parallels to Farmer Perkins' unbusinesslike procedure of hiring a man to cart the fertilizer from the station while his own facilities are growing cobwebs?

CUBAN SUGAR OFFERS OPPORTUNITY TO AMERICAN SHIPS

Suppose, for example, it dawns upon them that the Cuban sugar crop, used almost entirely by the American people who have the largest sweet tooth of any peoples in the world, is brought to our Atlantic ports every year by alien ships, while several of our large rivers, which empty into the Atlantic Ocean, are harboring vast fleets of idle ships owned by the government. And among these fleets swinging idly at their anchors are ships whose size especially adapts them for traffic to Cuban ports where the sugar shipments are made. As the sugar season is in the winter months, hundreds of seafaring officers and men are idle and available

to man these ships; repair yards and drydocks are only partly employed and willing and anxious to put these ships in condition for this trade. Does not this condition almost parallel the action of Farmer Perkins?

Before me as I write this is an item in one of our commercial dailies which reads as follows:

AMERICAN COAL EXPORTED IN FOREIGN SHIPS

"An American firm has just closed a contract to supply French Government Railways with 100,000 tons of American coal at \$7.25 c.i.f. It was learned yesterday that steamers of the Lloyd Royal Belge fleet will move this coal in equal monthly shipments at \$2.25 per ton during 1924."

Can you imagine that any shipper in Great Britain, receiving such an order as this, would for a moment consider delivering the coal in any but British bottoms? No, and very properly he would specify that the coal was to be delivered in English ships. We are so accustomed to being the "International Good Thing" that we overlook the fact that this might be an opportunity to keep this \$225,000 freight money in our own pockets. It is particularly interesting in connection with this order to note that the money for the freight is to be paid by the French government as the coal is to be used on their own railways, and so far as can be ascertained, there has been no interest paid on the huge war debt which France owes to this country, not to mention any attempt having been made to fund the principal as Great Britain has already done.

This money so generously loaned was obtained from the sale of Liberty Bonds and has not yet been repaid. As the bonds become due, it will be wrung from the pockets of every one of us now alive and probably from the pockets of our children and grandchildren. Each man, woman and child in the United States today is contributing by taxation, directly or indirectly, to paying the interest on these bond issues. Is it not time that "self-interest" should assert itself in this country? We are the most generous people on earth and we are all proud of it, but there comes a time when generosity is carried to an extreme. Those of us who pay direct taxes are complaining bitterly about the high cost of all commodities and we will never see the cost of living come down to normal conditions, until its prime cause, excessive taxation, is ameliorated.

In the case of the carrying of this coal abroad, if it were carried in government-owned ships and not a cent profit was realized in the transaction, the men who operate the ships, who furnish their supplies, and who make their repairs, would at least be making living wages and could help in paying taxes to be used in settling bond interest, which must be paid periodically, as the result of our generous impulses in loaning money to our European friends when they were in trouble. There should be justice in all transactions, and instances of this kind illustrate why we should be just to ourselves.

AMERICAN SHIPS SUCCESSFUL IN COFFEE TRADE

One of the finest examples of this kind is exemplified in the great American coffee cup. For years every American

who drinks coffee at breakfast has been paying tribute to foreign shipowners as no coffee is raised within our own continental borders. The great bulk of it has been and is now shipped from Brazil. Prior to the Shipping Board's establishment of lines to South America, the vast quantities of this staple commodity were carried to our shores in foreign bottoms. When we entered the coffee trade with our own ships, foreign competition, in order to scare us off from what they considered a vested right, reduced the cost to as low as 35 cents a bag from Santos to New York. Not scaring very easily, the Shipping Board continued these lines at a loss to the Treasury, and when it was seen that we were exercising our rights in this great trade, the freight rates have been advanced to what is a reasonable return from the shipments, and what is undoubtedly a much lesser rate than would now be prevailing, if there were no American ships in the business. Today we are carrying over 70 percent of this commodity, and the money for that service is being kept in our own pockets where "self-interest" dictates that it should be.

It is pleasing also to note what a little "self-interest" is doing in regard to our exports. Prior to the time of starving these South American lines, our exports to our American neighbors were almost negligible. Europeans, having ships, grabbed the business from under our very noses. Today, after only five years of American ship service, our exports southward have advanced by leaps and bounds. We now control the automobile trade in all countries of South America where American ships touch. See how far-reaching that one item of export is to our national prosperity. Thousands of people all over the country, but principally in the mid-West, have benefited by our increased sale of motor cars in a market which we had barely touched, and could barely reach before the advent of American ships to South American ports.

Of all our great industries which make us the most prosperous nation in the world, none will pay greater returns to the people at large than to maintain and build our own ships to extend our foreign trade. Self-interest in these lines of our industry will indeed be "good business" no matter how you approach it. Let us all take seriously the advice of Polonius to his son, "To thine own self be true."

Navy and Marine Memorial Dedicated to Americans Lost at Sea

WHILE the vital part played in our national life by the Navy and the merchant marine is fully appreciated by all thinking individuals, a public and national recognition of it is lacking and greatly needed. Innumerable memorials have been erected to commemorate various kinds of service in national life and activities in war and peace by exalting in tablets, medals and monuments of all sorts, deeds and virtues of individuals reflecting the ideal of sacrifice and worthy endeavor. However, service on the seas by the Navy and the merchant marine, though enormous in its portent and fraught with dangers and with great sacrifice, seems to have passed without appropriate national recognition. A movement is now on foot for the erection of a Navy and marine memorial to be dedicated to Americans lost at sea and to service on the seas.

The national committee which was formed to further the plan to erect this memorial includes: Col. Roosevelt, assistant secretary of the Navy; Admiral Benson, United States Shipping Board Commissioner; Chairman Farley, of the United States Shipping Board, and many others prominent in civil life and in the service. The executive committee of this naval memorial movement includes Col. Robert M. Thompson, Admiral Fiske, Walter Firth and others.

Preliminary information obtained from the historical section of the Navy Department indicates that the casualties in

naval and merchant vessel service during the war amounted to 299 ships flying the United States flag. The Americans lost in these vessels numbered 1,745. The total casualties in the United States Navy personnel during the war amounted to 7,367 officers and enlisted men, while the number of American troops lost at sea while being carried to the other side on foreign ships is very large. In addition, there were many non-combatants who lost their lives on torpedoed passenger vessels.

These great losses on the sea and the thought of the solitude and silence that surround them have inspired a monument of strictly marine character. The monument represents a wave or section of a wave with seven seagulls hovering over it. It is to be cast in bronze and the dimensions will be 19 feet by 29 feet by 32 feet. When mounted on its pedestal and foundation of marble the monument will be, from the ground to the topmost bird, 42 feet high. The greenish

Model of Navy and Marine Memorial

and blue patinas of the bronze will naturally reflect the colorings of the sea.

The work is of masterly execution and in its inspiration and conception opens up a new field in the history of creative art. It will in itself establish a permanent art interest in marine affairs for the country and show our gratitude for acts of bravery, the risks taken by sailors at sea and the long and faithful service of our Navy.

The monument design received favorable comment from artists and critics during its exhibition at 12 West 8th street, New York City, where it was shown in the studio of Daniel Chester French, the sculptor. Those who have seen it have expressed the opinion that it should be erected as a national monument, as a fitting memorial to Americans who have died in service on the seas.

The Capitol at Washington has been considered the most favorable location for such a memorial because it is the center of national interest, because it is readily accessible and because it would afford the serene background appropriate for the monument.

Any further information desired will be gladly furnished by A. M. Graham, 125 West 11th street, New York.

Shipbuilding in Great Britain Now at Lowest Ebb

Improvement Depends Upon Clearing Up of European Politics and International Relations and Absorption of Surplus Tonnage

By James Swan*

THE present unfavorable situation in the shipbuilding industry in Great Britain is the result of many different influences, all arising more or less directly from the war and the general state of disorganization left in its wake.

The unsettled conditions on the continent, particularly in the Ruhr valley, make a general and orderly revival of European trade at present impossible, and this affects more or less directly all other trade routes. The delay in general economic revival, more than any other single influence, is causing the unprecedented lack of demand for tonnage.

Of scarcely less influence upon the situation is the surplus of tonnage caused by the tremendous production of merchant vessels during and directly following the war, not only in Great Britain but in other countries which up to that time had not held important positions in overseas trade. The net result of this great shipbuilding activity, notwithstanding the enormous losses of ships due to submarine attack, has been to give the world in 1923 a far greater merchant tonnage than existed in 1914 and this in the face of a most acute trade depression.

It is not to be wondered at, in view of the conditions cited, that British shipping and shipbuilding activities are today at a low ebb, nor is it possible to foresee any substantial improvement until the horizon of European politics and international relations has cleared and the existing surplus of merchant vessels shall be absorbed.

LABOR SITUATION ANOTHER DRAWBACK

Concurrently with the depression already mentioned, which is world-wide in its effect, the British shipping industries are confronted by other difficulties at home. Chief among these is the labor situation. While strikes and similar agitations are by no means confined to Great Britain, they appear to be more far-reaching and of more serious and sinister effect there than elsewhere. Notwithstanding the low ebb which the business has reached and the dearth of new orders, there are still a considerable number of ships under construction and promise of some more, which will have to be built if existing lines and sailing schedules are to be maintained. One would suppose that at such a time the workers would be thankful for the little work that is in hand and by their efforts contribute to its execution promptly and economically. On the contrary, this peculiarly inopportune moment has been chosen for the declaring of a boiler makers' strike and in consequence nearly every shipyard is practically tied up and work has ceased, to the very great financial loss, not only of the workmen themselves but of the owners of the yards as well and of the other industries more or less dependent upon them for support.

Bad as is this situation in its present effect, it is having

a deeper and more serious influence. Continued unemployment is forcing the emigration to America of large numbers of skilled shipyard employees. Particularly is this true of the Clyde district where every outgoing ship is reported to be filled. These men, had they remained at home, would have continued in idleness, with no trade other than their own open to them, such is the strength of precedence and habit as well as union organization in the "Old Country." Once in the United States or Canada, however, unlimited opportunities exist, as a really skilled shipyard mechanic is useful in many different lines. This flow of emigrants is a matter of national importance and is being viewed with grave concern by those who have Britain's commercial welfare at heart.

As is usual in periods of industrial unrest, the productive

efficiency of the men has suffered, and British shipyards are, as the result of the keen competition brought about by the small amount of work offered, losing many contracts, particularly in the line of repairs, to German and Dutch concerns. It is only too apparent that, if Great Britain is to retain her position in the shipbuilding world, she will have to put her industrial house in order, and that in the near future Germany, once her present difficulties are settled, will prove a more formidable competitor than ever and one which can be successfully met only by the

Probably there has never been a period, certainly not within the memory of those at present engaged in the industry, when British shipbuilding has been at so low an ebb as now exists. Furthermore, it does not seem possible to predict, even in the vaguest manner, when a material improvement in conditions may be looked for. The general opinion appears to be that the lowest point of the "slump" has been reached and that any change will be for the better but few will venture any prediction as to when a change will come.

best of cooperation between employer and employee and hard work on the part of both.

SHIPS UNDER CONSTRUCTION

Turning to the detail of what is actually being done in shipbuilding; there is a small amount of work under way, mostly, up to the present, consisting of replacements of liners and similar large vessels lost during the war and necessary in order to continue established services. There are also some cargo vessels built and building for companies which maintain regular schedules, although it is doubtful if any of them can make money under present trade conditions.

Coming to the more technical or engineering side of the shipping business, the Diesel engine, in its various forms, is probably the most important question before British shipbuilders and operating engineers at the present time.

It is generally admitted that the Diesel has passed the experimental stage and has now entered upon a period of development, but it is pointed out by many shipowners that there are certain drawbacks or limitations to every type so far developed and that there is rather a long road yet to travel before anything approaching a standard type of engine is arrived at—in other words, a Diesel which represents a degree of development in internal combustion engines, similar to that held by the triple expansion engine in steam engineering.

Uncertainty as to the type of engine best to adopt, doubts

*Editor of MARINE ENGINEERING AND SHIPPING AGE.

as to the possibility of obtaining a supply of suitable fuel oil at all ports and the difficulty of obtaining trained engineers all contribute to an attitude of doubt in the minds of many shipowners as to the advisability of large investment in motorships. There is, however, such a small demand for ships of any type that it is not possible to say what the policy might be were trade conditions normal and shipping a remunerative investment.

In the meantime, a most active interest is taken in motorships and everything connected with them. Various types of Diesel engines are being developed by different builders, and there are several which give satisfactory results. By far the larger number at present in use are of the four-cycle type, but the two-cycle seems to be regarded with increasing favor, although it has not as yet had the benefit of such extended use, and consequent operating experience, as the four-cycle.

In general, the superior economy of the Diesel engine is readily admitted and its eventual general adoption considered as certain, but until trade conditions have greatly improved and the demand for ships is such as to justify the greater expenditure involved, an extended adoption of this class of machinery does not appear probable.

Owing to the very considerable weight of the Diesel engines at present being commercially produced, their use has been practically confined to vessels of relatively low power, although at least one large motor passenger ship is under construction. It seems altogether probable, however, that installations of Diesels in high speed ships of great power will become a possibility in the not distant future. Double acting engines of both the four-cycle and two-cycle types are now under construction or in experimental operation which promise a very considerable reduction in weight per horsepower, and this, coupled with the great saving in weight of fuel and fresh water made possible by this type of machinery, would seem to indicate the early advent of the Diesel-driven passenger liner.

THE SUPPLY OF OIL FUEL

The question of oil fuel supply, both for motorships and

Get Out of the Shipping Business

WE trust the coming congress will disentangle its common sense from its politics long enough to get the government out of the shipping business.

The United States is not socialist. Our people in the main do not want the government to run business, although under one provocation or another they have permitted a considerable extension of political control over private activities. But the business of shipping is about the last industry which a government is fitted to manage. Success in building up and operating profitably a merchant marine can only be won by a complicated combination of private initiative, world-wide knowledge and experience of transportation, traffic and merchandising. Its problems are many sided and fluctuating. No sensible man who knows anything about the conditions with which the expert in shipping must deal can hope that a government bureaucracy, even if it could be free from political pressures, could evolve or direct successfully a great national marine.

We believe every man in congress, except a few impracticals or politicians hoping to win votes on the government ownership appeal, realizes this to be the unquestionable fact. Then why not have the courage to act up to it and stop now the money waste of government operation and the injury to private enterprise which government operation inflicts?

The first loss to us is told in statistics. The second cannot be, but it is a worse evil. We cannot hope for a vigorous growth of American shipping as long as private enterprise has to fight the unlimited resources of the government. The whole nation is injured by this obstruction. It should be removed without further procrastination, even though a large sum has to be charged off on our books to get free. It will not be as large a loss as we are suffering and will continue to suffer from the continuation of government management.
—*The Chicago Tribune.*

oil burning steamers, is receiving much attention. In some quarters, the permanency of this supply is apparently looked upon with some doubt, although with the Persian oil fields at her command it would seem that Great Britain has little to fear on this score. Many leading engineers and shipowners are of the opinion that oil is too valuable to be used for the generation of steam in any ships other than those of relatively high power, and that cargo vessels, particularly tramp steamers, should use only coal. The necessity of conserving the available supply of fuel oil is being advanced as an argument for the adoption of Diesel engines, but until oiling stations are distributed along the world's trade routes to meet all possible requirements, the general use of these engines in tramp steamers appears doubtful.

TRADE DEPRESSION GIVES OPPORTUNITY FOR SCIENTIFIC DEVELOPMENT

There is one feature of all periods of trade depression which should not be overlooked, and that is that opportunity is given for technical and scientific investigation and development not possible under stress of great production and the endeavor to turn out a maximum amount of work. That this is being taken advantage of in England today is evidenced by the work of Diesel engine builders and also by the movement to introduce standardization of ship machinery and fittings.

There can be no doubt of the eventual revival of the world's shipping business and that Great Britain will have her share in this revival goes without saying.

Its shipping is necessary to the existence of the British Empire and that this ship-

ping will be maintained at all costs cannot be doubted, even though the revival and future development are in the face of more serious competition than has heretofore existed.

TO COOPERATE WITH DEPARTMENT OF COMMERCE.—With a view to establishing an effective point of contact between associations interested in the merchant marine and the Department of Commerce as to lighthouse, steamboat inspection, coast survey and navigation questions, a committee has been appointed to represent the associations.

American Marine Congress Adopts Resolutions Outlining Constructive Policy for Merchant Marine

Consolidates Views of One Hundred National Organizations into Shipping Program for Guidance of National Legislators—Plans Permanent Organization

THE Marine Congress which assembled at the Waldorf Astoria Hotel in New York City on November 8 at the invitation of the American Marine Association to work out a practical plan for the development of the American merchant marine was attended by representatives of about one hundred organizations directly or remotely interested in transportation by water. Col. E. A. Simmons, chairman of the Central Committee, presided and in his opening remarks told his hearers how warmly the late President Harding had supported the movement and read the letter from President Coolidge reproduced on this page showing the appreciation of the Administration for the efforts which the Marine Congress is making for the development of American shipping.

After extended deliberation the Marine Congress adopted twenty-two resolutions outlining a constructive policy for American shipping. The resolutions reflect the general opinion that the merchant marine should be privately owned and operated and that the Government should retire from active participation in the operation of mercantile vessels. Furthermore, the universal wish was expressed that the potential menace of a large and uneconomical fleet of idle vessels should be removed, and that the Government should immediately dispose of the large number of its vessels which have no value as competitive units.

The resolutions adopted were as follows:

RESOLUTION No. 1

Part A. Resolved that the United States Shipping Board and Emergency Fleet Corporation should retire from the business of operating ships, and place the operation in private hands, at the earliest practicable date.

Part B. Resolved that the United States Shipping Board should immediately scrap such vessels as are inferior in design, equipment or condition.

Part C. Resolved that the Shipping Board should offer its remaining vessels for sale to American citizens without any restrictions, and without discrimination between buyers and ports.

Part D. Resolved that after the lapse of a reasonable time all of the vessels not sold under the foregoing plan and having no immediate prospective sale value, should be scrapped.

President Coolidge's Letter to Marine Congress

Part E. Resolved that there are some freight and passenger and mail services maintained by Shipping Board vessels, the continuance of which may be considered as essential to our national interests. If the Shipping Board is unable to find buyers for the vessels in such services, they should be placed in private hands under an operating arrangement until buyers can be found or developed or the impossibility of profitable operation be definitely established.

RESOLUTION No. 2

Resolved that American shipping should be conducted by private American owners and that all merchant ships owned by the Government should be transferred as rapidly as possible to private ownership. Under no condition should government owned lines compete with private lines but, if for the purpose of expanding our trade, new lines are established by the Government, they should be as rapidly as

possible transferred to private ownership.

RESOLUTION No. 3

Resolved that the Secretary of Commerce and the United States Shipping Board be requested to proceed to have the navigation laws of the United States modernized, codified and made comparable with those of our successful maritime competitors.

RESOLUTION No. 4

Resolved that the unparalleled success which has attended the reserving to American ships of first our own mainland commerce and that of our commerce with Alaska, Porto Rico and Hawaii, justifies and demands the prompt extension of that national policy to our own commerce with the Philippines.

RESOLUTION No. 5

Resolved that we urge the adoption of a national policy reserving the transportation of not less than one-half of the total number of immigrants admitted to the United States in any fiscal year to vessels registered or enrolled and licensed under the laws of the United States.

RESOLUTION No. 6

Resolved that we favor the enrollment under suitable regu-

lations as to pay, qualifications and duties of officers and men of the Merchant Marine in the Naval Reserve of the United States.

RESOLUTION No. 7

Resolved that we favor the carriage of governmental officials and employees and supplies by privately-owned American ships and the restriction of ocean travel by government officials and employees to American ships when available.

RESOLUTION No. 8

Resolved that we heartily approve the enlightened policy of the Post Office Department under the Merchant Marine Act of 1920, and that we strongly urge the Department to continue to transmit the mails by American steamers whenever this can be accomplished with the least possible delay.

RESOLUTION No. 9

Resolved that the rail and ocean transportation media be drawn together and made to function as one transportation system to all parts of the world; and be it further

Resolved that permission be given to railroads and American steamship lines to enter into cooperative agreements to divide their said joint rates in a manner similar to that universally pursued in the division of rates on domestic and traffic via Canada; and be it further

Resolved that such arrangement shall not be permitted with respect to American railroads and foreign steamship lines.

RESOLUTION No. 10

Resolved that an earnest effort be made on the part of the Administration to amend existing treaties with a view of the establishment of preferential customs duties on goods carried by American ships and tonnage dues paid by American ships.

RESOLUTION No. 11

Resolved that a system of preferential rail rates for goods and passengers carried in American ships be made effective.

RESOLUTION No. 12

Resolved that we adopt the policy of allowing our railroads to apply export rates on materials used in the construction of American ships and on supplies used therein.

RESOLUTION No. 13

Resolved that it is essential to the permanence of the American merchant marine that American ships be properly built, manned, equipped and operated, and that all equipment and appurtenances be kept at a high state of efficiency and that the cargoes carried be properly loaded, safely carried and delivered; it is recommended that a proper uniform load line law be enacted, and it is further recommended that all American vessels be classified in the American Bureau of Shipping; and that loading of cargo be inspected by the Board of Underwriters and a loading certificate be obtained in the case of vessels engaged in overseas trade, and that the vessels be insured in the American Marine Insurance Syndicates, and that in the event of any loss or damage the services of these associations be immediately availed of.

RESOLUTION No. 14

Resolved that the National Congress repeal all laws that admit foreign-built ships, including yachts, to American registry, and eliminate the 10 percent excise tax on pleasure boats built in this country.

RESOLUTION No. 15

Resolved that the practice of placing contracts for repairs to government (other than naval) vessels on a basis of estimated cost without guarantee, in competition with bids of private interests, is unfair and should be discontinued.

RESOLUTION No. 16

Resolved that the chairman of the United States Shipping Board be requested to have prepared and cause to be released as public information a report of the recent survey of its idle or other tonnage suitable for conversion into vessels equipped with oil engines, and to include therein a fairly comprehensive statement of physical condition of such vessels. That the Construction Loan Fund established by the Merchant Marine Act of 1920 be made available for loans for the conversion of suitable government owned steam vessels to motor vessels and for equipping them with such new auxiliaries as this conversion would necessitate. That purchasers entering into agreement for such conversion shall be enabled to borrow, from the fund named in above paragraph, to an amount not exceeding two-thirds of the cost of complete conversion under the same terms and conditions as are now provided for in case of new construction. Such costs of conversion to include shipyard charges for installation and necessary repairs and alterations to hull as well as the costs of main engines and auxiliaries, while the remaining one-third of all such costs are to be borne by the purchasers.

That the government be encouraged to continue to sell such vessels for such conversion under the most advantageous terms to the purchaser.

RESOLUTION No. 17

Resolved that the Congress strongly endorse the movement for elimination of waste and simplification of practice initiated by the United States Department of Commerce, the American Marine Association, the United States Shipping Board Emergency Fleet Corporation and the representatives of the marine industries and the organization by them of the American Marine Standards Committee.

That the American Marine Standards Committee be commended to the interests in the marine field, for their encouragement and support, as a proper organization to point the way to needed economy in the design, construction and operation of ships and port facilities and allied industries, and one which, if properly encouraged and supported, can accomplish much to lessen the economic handicap with which our Merchant Marine is at present hampered and also to promote the construction of American ships in American shipyards.

RESOLUTION No. 18

Whereas a comparison of area and population of Europe as a whole and the United States discloses that although of similar area and commerce the United States has comparatively few well developed ocean and inland waterway ports while Europe has many, serving every section of its coasts and interior, and

Whereas the inevitable growth of the population and commerce of the United States will require many well equipped ocean gateways, therefore

Be it resolved that it is the consensus of opinion of the American Marine Congress that the development of an adequate number of ports be encouraged and that to that end equitable ocean and rail class and commodity rates for exports, imports, coastwise and intercoastal trade to and from such ports on an equitable basis be established and maintained.

RESOLUTION No. 19

Resolved that all bureaus of the Department of Commerce having to do with merchant marine affairs be consolidated under one head within the Department of Commerce.

RESOLUTION No. 20

Resolved that American citizens who travel abroad for business or pleasure, individually and collectively, including business and professional associations taking part in foreign

conventions, athletic teams, merchants and manufacturers who ship to and receive goods from foreign countries and all other American citizens who travel and ship by sea should consider themselves bound by patriotic duty to patronize American ships.

RESOLUTION NO. 21

Resolved that in view of the fact that liquor smugglers can readily transfer their present registry from the British to the French or Panaman or other foreign flags, and in view of the fact that most liquor smugglers at the present time are accustomed to anchor more than 12 miles off shore, and in view of the fact that the proposed treaty with Great Britain will give British passenger ships an advantage over all other ships including American, we earnestly urge the Senate of the United States in the interests of fair play to American shipping, to reject the proposed 12-mile treaty with the British Government.

RESOLUTION NO. 22

Whereas undoubtedly the American Marine Congress is especially interested in all matters pertaining to shipping, and therefore is vitally concerned with our export trade which

makes such shipping possible, they have therefore a vital point of contact with all other organizations interested in promoting foreign trade, and should cooperate to the fullest extent with these associations and with the proper governmental departments. We appreciate the force of public thought that may be created at such meetings as this, and the influence that discussions at the sessions and the resolutions that may be adopted by the Resolutions Committee play in the affairs of the nation. Much good can be done in co-operating with the various associations that have made this Congress possible and can assure you that this committee, having been appointed by the American Manufacturers' Export Association, will do all in its power to bring to the attention of that association any resolutions adopted by your Resolutions Committee for such investigation, study and recommendations as apply specifically to the purposes of their organization, which is—to *foster foreign trade*.

Be it therefore resolved, That the present Central Committee of the American Marine Congress take immediate steps to make permanent this first American Marine Congress, in accordance with the expressed desire and general thought expressed in its session.

A Remedy Proposed for the Shipbuilding Situation*

By Joseph W. Powell†

IN the years before the war our principal shipyards depended on naval contracts for the back log of their shipbuilding. The Limitation of Armament Conference definitely closed our naval expansion for years to come. The United States Shipping Board holds for sale a vast fleet of tankers, cargo vessels and passenger boats, and until this fleet is disposed of, the building of new vessels, except of special types, is rendered nigh impossible. Three years of falling freight rates and short cargoes have left few shipping companies in financial position to buy new tonnage even if they had the desire. In time, high railroad freights will act to increase water transportation in coastwise and intercoastal trade and will some day place these services on a remunerative basis. In the growth of this trade our shipbuilders can hope for a reasonable volume of orders. At present, the million gross tons of intercoastal shipping is not carrying full cargoes, but five years from now I believe two or three times this tonnage will find lucrative occupation on this route. This should mean a quarter of a million gross tons of new ships annually in this trade alone. Besides the Shipping Board's enormous fleet, there are on the ocean over six million gross tons of American flag ships. Beyond the new tonnage for intercoastal service this private fleet should purchase 300,000 tons per annum for its upkeep and expansion. So, once through the present depression, shipyards should be able to count on a building program of about 450,000 gross tons a year. To be optimistic, let us double this total which should take care of any building to meet favorable shipping laws that may be enacted, as well as all other causes.

What does such a program as this mean in terms of present building capacity? Barring another war, it is a fair prediction that as at present organized this industry cannot operate at 40 percent in any one year in the next five. This means excessive costs made worse by cut-throat competition. It means for many yards a process of starvation and eventual extermination. A shipyard is a difficult property to operate for any other business purpose than shipbuilding. Uses

may be found for boiler and machine shops. Steel shops may be employed in car building, and miscellaneous work for foundries, pattern shops and pipe and sheet iron shops may be found as makeshifts to reduce losses from idleness. But, at best, these shops are ill adapted to any special work except that for which they were designed, nor do these outside jobs go well with shipbuilding endeavors.

This gloomy picture is of little avail, if there is no remedy to offer. Shipbuilders cannot go far in making more new shipbuilding business, but they can control within reason the business that is offering. They cannot hope to fully employ their total capacity, but they can reduce this capacity. When the Harriman interests found that their two shipyards could not be kept half full, they made one of the most constructive moves since the war, by accepting the drastic expedient of shutting up completely one of the yards and concentrating their work at the other. If the present yards are to operate independently, there is little hope of the concerted action necessary to improve present conditions. Too many divergent factors enter the problem. But if several large combinations of principal builders could be effected, the first step towards a solution would have been accomplished. With a large majority of the industry in, say, three combined companies, these combinations should shut down and dismantle the proportion of their building capacity, the most important move in righting an impossible situation. Then by exchange of estimates of cost on all new work *before* bids are submitted and exchange of *actual cost* on completed work, bid prices could be brought within reasonable limits and the present disgraceful competition stopped.

I do not underestimate the difficulty of carrying through this proposal. Closed yards mean lost positions, and it would be beyond human nature to meet such proposal free from bias. The difficulty of adjusting values and agreeing to any combination can be magnified by want of belief in the proposed remedy, and many other good reasons can be advanced against any drastic action. But the cold facts of the situation still endure and, if my analysis is nearly correct, lead to one end. We shall await with deepest interest the solution to this problem.

* From an address delivered at the annual banquet of the Society of Naval Architects and Marine Engineers in New York, November 9.

† Former president, United States Shipping Board, Emergency Fleet Corporation.

An Adequate Merchant Marine Essential for the Nation*

The Future Greatness of the United States Depends Upon Increasing Her Commerce with the Outside World

By Rear Admiral Charles P. Plunkett, U. S. N.**

THE immediate problem which we face is not the building and supporting of a merchant shipping so much as it is a problem how to deal with what we now possess. Based on thorough information, the present seems to be a period of too much uncertainty and no probable future. It is not contended that the American people do not want a merchant marine. They not only want it, but their Congress has taken some of the steps necessary to provide it, and the policy which they have approved would provide for a suitable merchant marine. Unfortunately, there are features of that policy that would lead to endless embarrassment; namely, the denouncing of some of our treaties and the modification or cancellation of others.

The policy of direct and indirect aid to merchant shipping is not new. It has been applied by all nations, and is still being used by the majority. The application of it at this time is a question which we must consider. Nobody yet has accused the American people of trying to get something for nothing, but, undoubtedly, there are a great many people who, in discussing the question of the merchant marine and in refusing to give it the same consideration that we have given to other means of transportation which have been developed in the country, seem to think that the merchant marine can be brought to life and kept going on a profitable basis without any expenditure or contribution on the part of all the American people.

FAILURES HAVE DEMONSTRATED DIFFICULTIES OF THE PROBLEM

Undoubtedly, many private individuals have sunk their last dollar in an effort to demonstrate their capability to operate ships with little or no outside assistance. These efforts have only demonstrated the public spirit of these individuals, and their failure has not caused any great amount of comment among the great mass of the people, who seem to applaud only the successful. But these men have been successful for our purpose, for they have demonstrated the difficulties of the problem of placing upon the seven seas an American merchant marine, consisting of American-built ships, manned by American citizens, and carrying the products of American industry, all under the American flag! President Harding, in his address to a joint session of the Senate and House of Representatives on February 28, 1922, offered a perfectly feasible and proper plan to save our merchant marine.

Who can look back only as far as 1914 and not realize the immense importance of a nation's potential strength and resources in a proper merchant marine? Who can look back to 1917 and not realize the helplessness of the greatest nation on the face of the earth when confronted by a demand for help? Not help that you had all the time in the world to provide, even supposing you had all the money that you needed, but help that was needed instantly and in quantity.

Who does not believe today that, unless America gets behind her merchant marine, the elements combined with other features will reduce to a state of helplessness that with which we found ourselves possessed at the end of the Great War? What is to become of our building and repair yards? Just suppose they have to go out of their present

business. How long will it take to gather the necessary technical and operating forces to again produce and maintain shipping?

No one in America is predicting war, but everyone in America is thinking of a greater America! Upon what lasting, peaceful basis can America ever be greater, except through the increase of her commerce with the outside world? And upon what basis can she derive that greatness except through the ownership of a merchant marine capable of handling at least fifty percent of that commerce in order to keep down the exorbitant and excessive rates which would certainly follow foreign domination of our sea-borne commerce, not to mention the thousand-and-one little discriminations in trade all over the world, all of which react against the American producer and farmer?

MERCHANT SHIPPING IS MORE THAN A SECOND LINE OF DEFENSE

We of the Navy can operate away from the coast of the United States just as far as the American merchant marine can support us, and no farther. If the Navy is our first line of defense, then the merchant marine is so near to it that it is not entirely a second line of defense! It is so nearly in the trenches with the Navy that it can hardly be called a second line of defense.

Nobody begrudges the other nations the success which they have attained in ocean-borne commerce, but the American is not an American who idly sits by and sees his business carried on by other nations in a manner and after a style dictated by our industrial and agricultural competitors.

There is no reason, except utmost emergency, which should warrant an American citizen to take passage for any port in the world on other than American vessels, nor should there be any reason why more than half of the ocean-borne commerce of this country should travel under any other but the American flag!

The time element is the most expensive element entering into human life. No one should ever work on a basis that they have plenty of time. It is entirely reasonable to use adequate time where a big decision is to be made, but the American people have decided that they want an American merchant marine—the decision in this case has been made. Are we to allow the time element to absolutely and utterly destroy that which is absolutely essential that America can maintain herself in security in time of peace and also in time of war?

BANKERS' COMMITTEE ON MARINE SECURITIES.—Recommendations that the government should retire from the shipping business as soon as possible without interfering with existing needs of trade, and that the La Follette seamen's act and other laws which tend to increase the cost of ship operation should be modified, were contained in the report of the committee on marine securities adopted at the annual meeting of the Investment Bankers' Association held at Washington on October 31. The committee also expressed the opinion that a definite statement of policy should be made by the Shipping Board that it will remove government competition on any essential trade route which will be taken over by private interests. The committee believes ways and means must be found to finance the shipping business conservatively.

*From an address delivered at the Marine Congress Banquet at the Waldorf-Astoria Hotel, New York, November 8.

EXHIBITS AT THE MARINE EXPOSITION

General View, Main Aisle, Marine Exposition

New and Interesting—

devices shown for the first time at the annual Marine Exposition, held at the Grand Central Palace, New York, November 5 to 10 under the auspices of the American Marine Association, are illustrated and described in the following pages, together with views of many of the exhibits at the Exposition. As indicated by the large number of new products displayed and the great variety of exhibits, the Marine Exposition this year marked a notable period of progress in the marine industries and reflected in no uncertain way the growing interest of the nation in maritime affairs.

EXHIBITS AT THE MARINE EXPOSITION

Rear End Front-Operated Soot Blower

A SOOT blower of the Diamond type, designed especially for cleaning the rear end of Scotch marine boiler tubes and operated from the front, was shown at the booth of the Diamond Power Specialty Company, Detroit, Mich. The principle of cleaning Scotch boiler tubes by these blowers is to blow the soot with the draft up the stack.

Cross Section Type BBM Diamond Soot Blower

It was specially developed for double end Scotch boilers or for a single end boiler so close to a bulkhead as to prevent the installation of the rear end type blower.

The model BBM blower may be installed in boiler tubes of 2-inch inside diameter and larger. It is housed in the boiler tube proper, the units nearest the center of the tube bank being selected where possible. Operation is by means of a removable handle, which passes through the uptake doors and engages a simple mechanism, which permits the blower to be advanced through its enclosing tube back into the combustion chamber, step by step, at the same time being rotated about its horizontal axis. Through the combination of these two motions, the steam jets describe constantly-widening cones which clear the tube surfaces. After blowing, the blower is drawn back into its protecting tube by a straight pull and the operating handle is detached.

Automatic Feed Water Regulator

THE Babcock & Wilcox Company, New York City, demonstrated a new type of patent automatic feed water regulator at the exposition this year. It is claimed that by reason of its free circulation and the comparatively large amount of water it contains, the B. & W. watertube boiler requires generally little attention to keep a constant water level, and in vessels of the mercantile marine in which these boilers have been fitted, feed water regulators are frequently dispensed with. In large installations of boilers, however, it is preferable to fit them.

The new regulator designed for this service consists of a hollow cylinder, which is rotated on its axis by means of a float and lever placed inside the boiler. The cylinder has ports cut diagonally along its walls, and works in a liner having corresponding ports. The liner is fitted in a casting or box which is attached to the boiler shell, and has one branch for a feed check valve, and another branch for a pipe

leading to a non-return feed valve located on the boiler drum.

The cylinder is moved lengthways along the liner by means of a suitable adjusting screw and spindle, the spindle being connected to the cylinder by ball bearings, so that friction is reduced to a minimum.

Attached to the spindle, between the adjusting wheel and the gland, is a lever and rod, the latter extending to a position in the stokehold, where it can be easily worked by hand from the firing level.

The action of the apparatus is as follows:

OPERATION

The feed water enters by the feed check valve into the hollow cylinder, and, if the water in the drum is low, passes through the ports of both cylinder and liner to the valve box, whence it travels through the pipe and non-return valve into the boiler.

The position of the cylindrical valve is entirely regulated by the float in the boiler. When the level of the water in the boiler is low, the ports will be open, and as the water rises in the boiler and carries the float with it, the cylindrical valve will be moved around, and the ports gradually closed.

The height of the level of the water in the boiler can be maintained at the position desired by moving the cylinder lengthways along the liner. This is done by turning the

Assembly of Feed Water Regulator

hand-wheel of the spindle attached to the cylinder, the travel of which, as the ports in both cylinder and liner are placed diagonally, will ensure an alteration in the point of cut-off relative to the position of the float.

There is a suitable indicator on the adjusting wheel showing which way it should be revolved for the higher or lower water level, and there is also an indicator on the spindle itself showing when the valve is at the highest, lowest, or any intermediate position.

EXHIBITS AT THE MARINE EXPOSITION

EXHIBITS AT THE MARINE EXPOSITION

Improved Connecting Shackle

THE National Malleable Castings Company, Cleveland, Ohio, had on display an improved type of connecting shackle having the general design of a standard stud link. It is an ingenious device and can be used either in regular service or as a repair link.

Improved types of connecting shackles which are narrower in width than the old type, resulting in easier operation over the wildcat were also on exhibit.

New Asphalt Decking

THE James Coffey Engineering Corporation, New York City showed a section of "Minralite" Mastic flooring in its booth. This material is a high grade rock asphalt mastic combination of natural asphalt, refined and brought to the work in barrels, heated in specially constructed kettles and reinforced with mineral aggregate of various sizes, and carefully selected and graded.

This mix is then heated to the proper temperature and laid on the foundation which is to receive the mastic material.

It is stated that the method of laying "Minralite" Mastic and the preparation of the surface on which it is to be laid has been brought to a high state of perfection through actual practice and years of contracting and observation of the material in service.

The thickness of this floor depends upon the service required.

The features of this mastic as stressed by the company are that it is a preventative against corrosion; that it prolongs the life of the plates; and that the cost of maintenance is reduced.

Static and Dynamic Balancing

THE Vibrator Specialty Company of Philadelphia, co-operated with the Akimoff Propeller Company in demonstrating the combination static and dynamic balancing machine at the exposition. A 24-inch diameter bronze propeller was mounted and the method of operation explained. The machine can be instantly set for static or dynamic balancing and gives, as the company states, results of greatest accuracy. It gives the plane and the amount of correction to be applied to the body to make it operate smoothly *i.e.*, in short vibrations. Machines of this type find wide application in industrial plants to accurately balance crankshafts, fly-wheels, propellers, armatures, pulleys, etc.

Larger machines for balancing turbines and rotating fields, weighing up to 15,000 pounds are manufactured by the Vibration Specialty Company.

Not long ago the Vibration Specialty Company balanced five turbo-generators of the S. S. *Leviathan*. The portability of the machines made it possible to bring them into the turbo-generator compartment of the ship. Results were secured which exceeded all expectations.

The Akimoff Propeller Company also exhibited models of propellers built entirely along the lines of the circulation theory. These propellers look very much like any other but are developed on a radically different basis tending as it is claimed to unusually high efficiency.

Automatic Control for Cargo Winches

IN the General Electric Company exhibit at the recent Marine Show at the Grand Central Palace were included three pieces of apparatus of especial interest. These were a magnetic winch control, a portable, electric air compressor and a 500-watt turbine-generator.

All the electrical equipment for a single cargo winch installation was included in the magnetic winch control. This consisted of a General Electric type COM waterproof motor, with shoe type load brake especially designed for mounting on the open deck of a vessel where occasional submersion is to be encountered; a master controller of watertight construction, and a magnetic panel with accelerating contactors, overload protection and resistors mounted back of the panel. The panel was of the open type for mounting in a protected place.

This magnetic control is of strong construction, and is simply operated. It is superior to the drum controller handling motor currents due to the fact that the automatic contactors allow for the time element required in accelerating or decelerating motor speeds. The handle on the magnetic control can be moved easily and rapidly, whereas, on the drum controller, this operation must be done more slowly to definite points to prevent any possible burning of control fingers and segments and to allow an even movement of load.

An emergency switch is provided with this control, placed close to the operating handle. By means of this, the winch can be stopped in any position, the load brake set and the current cut off the motor.

The portable air compressor which was on exhibit is a compact, electric motor-driven machine to work from three to five standard pneumatic tools at once. With this device holes may be drilled up to 1½ inches in steel, seams may be beaded and calked and steel may be shaped by chipping. The greatest use on electrically equipped vessels would be in blowing and cleaning dirt or dust from the windings of electrical machinery, ordinarily inaccessible for hand cleaning. Another use is found in scaling surfaces preparatory to repainting. The motor takes three horsepower when charging the reservoir and is automatically governed to maintain the pressure between narrow limits. This unit will compress 35 cubic feet of free air per minute to 90 pounds gage pressure.

The CY 32-C turbine-generator shown by the General Electric Company at this exhibit is adaptable for providing current for various illumination purposes on tugboats and other small craft and as an auxiliary unit on larger vessels. It has a rating of 500 watts at 32 volts and operates at 3,600 revolutions per minute. The turbine, which is of the non-condensing type, has a special form of governor. A self-contained pressure regulator maintains a constant nozzle pressure with boiler pressures varying from 125 to 225 pounds or 70 to 170 pounds. The generator in turn maintains a constant load on the turbine by means of an eddy current brake coil which automatically compensates for any change in electrical load. The elimination of the usual type of mechanical governor simplifies the design so that there are but fifty separate essential parts in the entire machine and but one adjustment, that of the tension of the spring in the pressure regulator.

EXHIBITS AT THE MARINE EXPOSITION

EXHIBITS AT THE MARINE EXPOSITION

American Brass Company Has New Lead Covered Cable

THE American Brass Company, Waterbury, Conn., recently purchased the National Conduit and Cable Company, Hastings-on-the-Hudson, New York. This company is now known as the Hastings-on-the-Hudson branch of the American Brass Company. The principal new product being handled by the American Brass Company, made possible through this purchase, is lead-covered copper cable of many varieties used for power transmission service.

Bethlehem Corporation Producing Plant Mills Direction Indicator

THE Bethlehem Shipbuilding Corporation, Ltd., demonstrated the Plant Mills direction indicator and engineer's alarm at its booth this year. The rights for the manufacture of this device have been taken up by the Bethlehem people, who are manufacturing it at present at the Union Plant, Alameda, Cal.

This device is used as an aid and safeguard in maneuvering vessels at close quarters. The direction indicator keeps the navigator wherever he is on the bridge constantly informed as to the handling of the engines and the engineer's

Plant Mills Direction Indicator Demonstrated at Marine Exposition

alarm provides a prompt and efficient means whereby the engineer is instantly and automatically warned should he fail to operate the engines in accordance with directions from the bridge.

The bridge indicator, visible from any part of the bridge, shows the speed and direction of the engines; a white light flashes from three upper lenses for every revolution ahead and a red light flashes from three lower lenses for every revolution astern.

By means of flashing red lights and alarm bell in the engine room, the engineer is warned of an error in answering the bridge signals, the alarm operating until the error is rectified. Parallel wiring is used throughout the system.

Control Station for Dredge

THE Westinghouse Electric & Manufacturing Company exhibited the pilot house control station and the corresponding engine room main control panel which will be used for controlling the two 800 horsepower propelling motors on one of the four new 5,000-ton Diesel electric sea-

Pilot House Control for Army Dredge

going hopper dredges now being built for the United States Engineer Department.

By means of two hand wheels on the bridge control pedestal the pilot has complete individual control of the two propelling motors. It is claimed that this is a great advantage on a ship which has to do a great deal of maneuvering. The control pedestal also carries instruments showing propeller revolutions and the load on the motors.

Similar equipment is mounted on the engine room panel, together with a transfer switch by means of which the control may be connected to the bridge station or to the engine room station. The installation is illustrated and described in the "Westinghouse Marine Log" now being distributed in the Westinghouse booth.

Novel Gyrating Electric Ceiling Fan

THE Diehl Manufacturing Company, New York City, is seeking an appropriate name for a novel type of gyrating ceiling fan which was shown at the entrance of booth No. 31 at the Marine Show.

The fan motor was mounted in a ceiling base and supported by ball bearing pivots in such a manner that the motor is free to swing in any direction on the principle of a universal joint. The motor itself also has ball bearings and means are provided to prevent grease or oil from escaping at the lower end. The motor shaft extends downward and carries a 6-blade fan wheel, which may be either 12 inches or

EXHIBITS AT THE MARINE EXPOSITION

EXHIBITS AT THE MARINE EXPOSITION

16 inches in diameter. The blade is protected by a suitable guard. At the upper end the shaft is connected through a reducing gear to a lever which is attached to the base by a ball and socket joint. The gear reduction is such that when the fan is running at normal speed the lever causes the motor body and fan blades to gyrate at about 6 revolutions per minute. During this gyration the motor shaft always remains at

demands of owners for a range that would use inexpensive oils safely and with cleanliness. It is stated that the oil burner part of the equipment is of simple construction and requires little more attention than the burner on the ordinary domestic oil stove. The oil is fed to the burner by gravity, no mechanical aid being necessary for either atomizing the oil or for furnishing air to the burner.

New Diehl Gyration Fan

a fixed angle of about 30 degrees to the vertical axis. This angle may be varied to suit local conditions by changing the length of the driving lever at the top.

The fan thus throws a cone of air, with the apex of the cone at the center of the motor. This feature has suggested the names "Aerocone" and "Conovair."

Arc Welder for Ship Work and New Galley Range

THE Todd Shipyards Corporation in its exhibit showed the Todd twin-pole arc welder which has been developed especially for use on board ship where it comes into service in the repair of leaky seams, fire cracks, leaky pipe joints, worn machinery parts, loose or broken rivets and other essential repairs that can be made by welding.

The Todd welder has been designed for quick work and its small size and weight, it is said, particularly adapt it for ship service. It is 28½ inches in overall length and driven from any plant generating 110 volts direct current or from other similar sources of power supply. It is readily portable and designed for a single operator.

The Todd representatives are calling the welder to the particular attention of shipowners and operators.

NEW GALLEY RANGE

Another feature of the Todd exhibit was a new type oil burning galley range which has been developed to meet the

Ship Type Arc Welding Unit

The burner is placed in the center of the range with flues to right and left around the ovens, permitting even regulation of the temperature of the ovens. The oil supply line to the burner on the front of the stove is equipped with a sight feed oil box, in which the flow of oil can be observed.

The range is built of blue annealed mild steel of the highest grade and it is stated will withstand rust, corrosion, hard usage and wear. Castings are of the best grade of gray iron. All exposed sides are insulated with genuine asbestos mill board.

It is fitted with one firebox and two ovens, the range measures 98½ inches in length, 26 inches in depth and

New Oil Burning Galley Range

stands 36 inches high. Its design permits it to be taken apart in five distinct units, handled through a small door and reassembled inside the galley.

The top of the range is made of cast iron, ¾ inch thick on the ends, increasing to a thickness of 1½ inches in the center. Heat will not warp it. The top is polished for use as a grill and is fitted with a gutter completely surrounding the edge of the top to catch the drippings from overflowing.

EXHIBITS AT THE MARINE EXPOSITION

EXHIBITS AT THE MARINE EXPOSITION

This eliminates danger from fire and makes for cleanliness. Adjustable and interchangeable sea rails are also fitted.

The ovens are of large size, 18 inches by 26 inches by 25 inches, equipped with doors of extra heavy construction, counterbalanced and with protected springs. Door handles are designed to permit the doors being left open one inch for light cooking.

Large flues have been provided around the ovens and a specially designed by-pass damper cuts out the flues, permitting a direct passage from the burner to the stack. This permits the range to be quickly started up.

Bibby Flexible Couplings Manufactured by Falk Corporation

THE Falk Corporation, Milwaukee, Wis., had on exhibit for the first time a flexible coupling invented by James Bibby and manufactured in England by the Wellman-Bibby Company. The Falk Corporation has acquired the exclusive manufacturing rights in the United States of

ing of the grooves is in the form of an arc of definite radius and is produced by machines specially designed for the manufacture of these couplings. The radius of the arc bears a definite relationship to the thickness of the spring bars and is designed so that when each bar is bent around this radius the stress in the spring cannot exceed a fixed safe value. Under light and normal loads, there is a long free span of spring between the points of support on the

Sketch of Falk-Bibby Flexible Coupling

the Bibby patents and has equipped its plant with a full line of very ingenious special machinery for manufacturing its couplings to take care of requirements in this country. The coupling will be known as the Falk-Bibby coupling.

This coupling consists of two flanged steel disks (one keyed to each shaft), two or more sequents of a tempered steel spring forming a continuous cylindrical grid, and a steel cover. On the periphery of the flanges are pitched cross grooves in which the spring is placed. The spring is the flexible member and its shape, and that of the grooves, forms the characteristic feature of the coupling. The grooves in the disk widen inward toward each other, so that the spring fits closely in them only at their outer ends. This widen-

Action of Spring Under Variations of Load

two flanges, which allows for considerable flexibility, but under heavy overloads the spring members become supported along the sides of the grooves thereby automatically shortening the span and stiffening the spring.

It is stated that the coupling will compensate for want of alinement of the shafts without setting up cross pulls as occur with belt type couplings. The amount of eccentricity which the coupling will accommodate is more than that caused by worn bearings before they require relining.

The flexibility of the coupling was demonstrated by a remarkable exhibit at the Exposition. A centrifugal pump was mounted on a tank, and driven through a Falk-Bibby coupling by a 5 horsepower motor. This motor was mounted on a plate which in turn was swung sideways so that during the operation of the pump at full load the centerline of the motor shaft was slowly swung sideways up to 10 degrees each way out of alinement with the pump shaft. In spite of this tremendous misalignment the set ran very quietly.

The Falk Corporation claims for the coupling a torsional resiliency which enables it to smooth out bad running conditions.

Improved Sash Balance

THE O. M. Edwards Company, Inc., Syracuse, N. Y., had on exhibition an improved marine sash balance. This device is designed to balance plate glass windows, especially those used on enclosed promenade decks of passenger ships.

The balance is made of bronze to provide against the action of salt water and is mounted away from the deck, so that water will not accumulate around it. It is stated that simplicity and the small number of movable parts add to the efficiency of this device. The entire device is of brass with

EXHIBITS AT THE MARINE EXPOSITION

EXHIBITS AT THE MARINE EXPOSITION

the exception of a steel coiled spring, which provides tension for the balance. This spring is inclosed in a brass cylinder packed with grease.

Tests of the device on the *S. S. President Harding*, under all conditions of weather, have demonstrated its merits.

Temperature Indicator for Cold Storage Compartments

THE marine electric thermometer which has been developed by the Wilson-Maeulen Company, 383 Concord avenue, New York, for many years manufacturers of a high grade of electric thermometers and pyrometers, was demonstrated at the exposition.

This thermometer is an apparatus with which the temperature of a number of stations can be determined within the

anism is mounted under the cover in a box casting of marine bronze; operating spindles of Monel metal extending through stuffing tubes to the indicating dials on the front. Connecting wires from the mechanism compartment pass through a stuffing gland at the lower side of the case and enter the upper side of the separate junction box casting where the electric connections are made to the cable from the thermometer bulbs. The galvanometer indicators are fitted in individual marine bronze cases. The scale window is of thick plate glass suitably protected.

These indicators respond to less than one-tenth of one degree F. change in temperature of the thermometer bulb and are necessarily sensitive. The galvanometer indicators are of the moving coil type and are built with only one pivot which is located at the geometric center of the coil and which is also at the center of gravity of the movement. This feature renders the indicator readings practically independent of mechanical vibration and of ship roll.

To operate, turn the station selector switch to the desired temperature point (each point being indicated by a positive click). Turn the temperature dial until the galvanometer indicator index deflects to its zero. The number at which the temperature dial then points, indicates the temperature of that particular bulb.

Salinity Meters

NEW equipment developed by the Brown Instrument Company, Philadelphia, Pa., to detect surface condenser leakage, evaporator priming and boiler water salinity was shown at the Exposition.

Electric Marine Temperature Indicator for Refrigerated Spaces

cold storage range. The apparatus comprises two dials, the one a temperature dial reading from 10 to 60 degrees F. and the other a station selector switch of 30 points. These two dials are mounted on a suitable panel and below them is a junction box. Two galvanometer indicators are mounted above the two dials, one being a spare. A separate waterproof switch is thrown to connect either indicator into the circuit.

Any number of electric thermometer bulbs (up to 30 maximum) may be located at suitable points where temperature is to be measured. Each thermometer bulb is connected to the indicator panel with a continuous armored cable. The temperature indicating dial and station selector switch mech-

Lamp Type Salinity Meter

It is claimed that this salinity detector, which is of the lamp type, eliminates the difficulties experienced with former designs of the lamp type. In this indicator the supply circuit feeds two parallel paths. Two lamps alike in characteristics are used in the circuit as visual indicators in the following manner:

EXHIBITS AT THE MARINE EXPOSITION

A cell is connected in series with one lamp while the second lamp is connected in series with a variable resistance.

It will be understood that if this resistance is adjusted so as to be equal to the resistance between the cell electrodes for a given concentration of salt in the water, the lamps will burn with equal brilliancy and be affected alike by line voltage. Consequently the observer's eye is provided with a standard for comparison, thus eliminating the personal equation and errors due to voltage variations.

Another feature incorporated in the lamp-meter is the provision for automatic temperature compensation. Temperature

the eddy currents generated in the disc. The torque in one direction is controlled by the current flow through the water surrounding the electrodes. Consequently it depends upon salinity of the water under test. The torque in the other direction is fixed and depends upon the current flow through a resistance. This resistance is so adjusted as to be equivalent to the resistance between electrodes at a definite salinity. Then, if the salinity of the water under test exceeds this predetermined value the disc will rotate and close a contact in the alarm or signal light circuit. If the salinity should be lower than the predetermined value the torque controlled by the fixed resistance will predominate and the meter disc will rotate in the opposite direction.

Automatic temperature compensation is secured by varying the resistance in response to temperature changes. The instrument, it is claimed, is practically free from voltage and frequency errors in that the circuit is differential and essentially equivalent to that of the Wheatstone Bridge. Vibration has very little effect on the meter because of the absence of fragile suspensions. The moderate accuracy, ruggedness and low cost make this instrument particularly suitable for marine service. Its construction renders it practically moistureproof. The compact form is also of advantage for installations under conditions where very little space is available. Alternating current is necessary for operation of this meter.

Combined Fire Detecting and Extinguishing System

A COMPLETE installation of the combined Lux-Rich System for detecting and extinguishing marine fires as it will be fitted on the motorships *Challenger* and *William Penn* was shown at the booth of Walter Kidde and Company, New York City, distributors for the system.

Another feature of the exhibit of this company this year was an electro-vapor radiator the American rights for which are controlled by the Walter Kidde and Company. The staterooms of the new Southern Pacific passenger ship being built at the Tacoma, Washington, yard of the Todd Shipyards Corporation will be fitted with these radiators.

New Developments in Fire Detecting Wire

A NEW feature in the exhibit of the Fire Detecting Wire Corporation, New York City, was their waterproof thermostatic wire. This company's wire was first developed for shore use, and the outer insulation was made of varnished cambric. Although this wire was moisture-resisting to a degree, it was not entirely suited to the severe conditions encountered at sea.

For this reason a waterproof wire was developed which it is claimed has successfully met the rigorous conditions of marine service.

A wall of uncured rubber was substituted for the varnished cambric. Tests made daily on samples submerged in salt water for long periods show this wire to be unaffected in any way.

An installation of 6,000 feet made in a ship last April is giving entire satisfaction.

Salinity Detector with Alarm Features

variations, if uncorrected, will produce substantial errors. For instance, if a sample of water at 150 degrees F. is tested with an instrument calibrated at 120 degrees F., an error of approximately 30 percent in the resistance will be introduced. To compensate for these errors the electrodes are so arranged as to move further apart as the temperature increases, thus producing an increase of resistance to balance the decrease due to the rise in temperature.

INDUCTION TYPE SALINITY INDICATOR

This meter was developed to meet the need for a rugged salinity indicator. The instrument, alarm bell, signal lamp and switch being mounted on a panel. The automatic alarm feature is of great value, in that it will instantly warn the operating engineer if condenser leakage or evaporator priming result in excessive salinity of the boiler feed.

The principle of operation is similar to that of the watt-hour meter. A light aluminum disc, running in jewel bearings, is rotated between laminated magnetic pole pieces by

Stream-Line Filters

ONE of the most interesting exhibits at the Shipping Exhibition recently held at Olympia, London, was the stream-line filter. This remarkable apparatus has attracted widespread attention in Great Britain and a company, known as the Streamline Filter Corporation, has recently been formed in New York with Mr. F. D. Herbert as president for its production in this country.

The stream-line filter is the invention of Dr. H. S. Hele-Shaw, the eminent British scientist and was described by him in a paper read at a meeting of the London Section of the Society of Chemical Industry in June, 1923, as follows:

In a paper presented recently to the Royal Society the author explained that he had in the course of certain experiments with thin films found that not only was it possible to separate the very finest matter in suspension from a fluid, but

even apparently to separate two fluids of different densities if the film were sufficiently attenuated. For the purpose of doing this he employed a fibrous or textile material impervious to the action of the fluid itself. The material employed was a form of water-proof paper.

It is important to show how it is that the stream-line filter of comparatively small size is able to deal with large quantities of fluid at moderate cost.

The essential points of the

Single Unit, Vertical Type Stream-Line Filter

stream-line filter are the employment of one or more packs of impervious material, preferably paper, on account of its lightness and cheapness, the pack being held between two ends called pressheads; also means of controlling the pressure according to the filtration required. With the view to economy the sheets in the pack are cut rectangular in form, and with a view of getting as large a filter surface as possible for what may be known as edge filtration as opposed to surface filtration, each sheet is perforated with an identical number of holes in such a way that the holes lie in alternate rows of large and small holes. When the sheets are put together in a pack (as in the case of the filter shown to the meeting, 4,000 or 5,000 sheets) the holes form tubes. If into one row of tubes the prefilter, or liquid to be filtered, is forced under pressure from the pressure head and the opposite ends of the tubes remain closed, there is no escape for the liquid except through the interstices of the sheets. The liquid passes through these interstices, leaving behind the matter in suspension in what may be called the inlet tubes, and passes down the smaller or outlet tubes. In the language of hydrodynamics, each large inlet hole in the sheet thus becomes a "source," and each outlet or smaller hole becomes a "sink." It is obvious that the area of filtration is represented by the area of the inner sur-

face of the larger cylindrical tubes, which is why these tubes are made larger. The smaller tubes are quite sufficient to discharge the filtrate.

By degrees a film is formed on the inner surface of the larger tubes, consisting of particles which are unable to pass between the sheets, and are thus filtered out from the general

Arrangement of Perforations in Sheets of Stream-Line Filter

body of the liquid to be filtered. Now there are obviously two important functions of the filter, one being that in which the object is to recover the liquid which has passed through the sheets in a purified condition, as, for instance, the case of filtration of water or oil, the suspended matter being dirt or impurity of some kind which has to be removed; in the majority of such cases removal of the impurity or dirt can be effected by opening up the larger tubes and washing through with the prefiltrate or fluid to be filtered. The other case is much more difficult, being that in which the solid matter left behind, or residuum or "depot," which may be solid or a viscous fluid, is the valuable material of which recovery is sought. In this case the washing out is never easy to effect, and is very often impossible, or at any rate impracticable. One mode of removing the material is by rods, in which case the

Diagram Showing Stream-Line Flow

filter is generally required to be opened. Other methods are under consideration and trial, but the object to be aimed at is undoubtedly to effect clearance of the solid matter in the way that the washable dirt is at present collected—namely, without opening up the filter, and if possible without employing such mechanical devices as involve the use of bevel wheels or spiral drums, actuated by external machinery, and requiring packing glands in the filter itself.

By putting a large number of packs together in rows, it is quite easy to see that as the operation of washing out the inlet tubes is a matter of, at most, a few seconds, it is possible to have continuous action, and only one pack at a time need be put out of action for washing. Suppose, for example,

Naval Architects' Meeting a Feature of Marine Week

Society of Naval Architects and Marine Engineers Discusses Economic and Practical Phases of Merchant Ship Construction and Operation

THE thirty-first general meeting of the Society of Naval Architects and Marine Engineers was held at the Engineering Societies Building, 29 West 39th street, New York City, on November 8 and 9, with President W. M. McFarland in the chair. Immediately following the opening of the meeting the secretary read the annual report. He commented at some length upon the loss in membership that had taken place after the peak membership attained during the war, but said that the gain in the past year had been quite as much as was expected and that a considerable part of the loss during that same period was due to elimination of members for non-payment of dues which had been too long delayed. The growth of the endowment funds was in good condition and steadily increasing.

Abstract of President's Address

There is an aspect of this period of depression on the side of personnel which is very serious and filled with danger to the profession. The dull times have thrown many highly experienced men out of employment and they have been forced to take up other lines. This is also true to some extent with consulting naval architects and engineers.

FIRST NATIONAL MARINE CONGRESS

At this time, in this city, there is in session the first National Marine Congress, in which our Society is represented and which is an effort to bring together all who are interested in the prosperity of the American Merchant Marine. The interests represented are not only ship owners and operators and ship and machinery builders, but exporters, manufacturers in general and the farmers. Thus it appears that an earnest effort has been made to bring together representatives of our whole people in the hope that by conference and discussion some scheme can be evolved which will meet with general approval and can be presented to Congress as representing the wishes of the nation.

VESSELS FOR COASTWISE SERVICE

What I have said with respect to the terrible depression in shipbuilding applies particularly to vessels for foreign trade. There is, however, a silver lining to the cloud when we think of vessels for the coastwise service and for our bays, lakes and rivers. For this service 36 vessels of 143,669 gross tons have been built in American yards from January 1 to November 1, 1923.

Orders have been placed for a number of large vessels on the Lakes. The Southern Pacific Company has recently placed an order for a large, thoroughly modern passenger and freight steamer for their line from New York to New Orleans, and two Eastern coastwise companies have placed orders for two vessels each which will be thoroughly modern in every way. It is also stated on good authority that a prominent shipping company on the Pacific Coast is about to place the order for a large, high speed passenger and freight steamer for service to the Hawaiian Islands. Other projects are under consideration and may materialize very shortly. All of these will mean work for our shipyards and give an encouraging aspect to prospects for shipbuilding.

With respect to the general survey of marine conditions, for large power houses on shore the tendency seems to be a very material increase in steam pressure and in the amount of superheat carried, so that there are a number of installations carrying 350 pounds pressure, a few that have gone as high as 600 pounds, and a few small plants have been built

for 1,200 pounds pressure to see what trouble will develop. The demand for economy in the production of power is so great that these large installations are neglecting no detail which will contribute to that end. It seems probable, if the experience with these higher pressures on land is satisfactory, that it will have an influence on the design of machinery for vessels, and undoubtedly our leading designers are studying this movement very carefully so as to be prepared at the proper time to bring out designs which will represent the latest steps in progress.

ELECTION OF OFFICERS

The following officers whose terms expired December 31, 1923, were re-elected:

Vice-Presidents: Homer L. Ferguson, Frank L. DuBosque, Henry A. Magoun, William A. Dobson.

Council Members: (Representing Members of the Society): Herbert C. Sadler, William H. Todd, Daniel H. Cox, Ernest H. Rigg, Charles F. Bailey, William McEntee. (Representing Associates): Herbert L. Aldrich, W. L. Marvin, M. D. Ferris.

Executive Committee: Walter M. McFarland, ex-officio; Stevenson Taylor, Frank L. DuBosque, Washington L. Capps, Joseph W. Powell, Andrew Fletcher, Homer L. Ferguson, Daniel H. Cox, ex-officio, Alfred Gilbert Smith.

Secretary-Treasurer: Daniel H. Cox. Assistant Secretary-Treasurer, Thomas J. Kain.

Additional Notes on American Shipyard Apprenticeships, Evening Schools and Scholarships

By Chas. F. Bailey

ABSTRACT

The advancement in shipyard apprentice work and evening schools during the last two years, while considerable, is apparently not as great as the progress in some of our large manufacturing corporations. This condition is to be regretted, but it is largely explained by the fact that during this period we have been, and still are, struggling for the very existence of the shipbuilding art, principally owing to the cessation of naval construction and to the small amount of new merchant tonnage now building. Due to the above considerations some yards have made but slight advancement, while others have even reduced their apprentice training or almost entirely done away with it.

With the Newport News Shipbuilding and Dry Dock Company interest in apprentice training has increased during the last three years or more, and it is now greater than at any previous time. The character of the boys and their attitude and bearing have uniformly improved during the last three years. The establishment of scholarships has also tended to raise the character of the apprentice applicants, and they now come with a better preparation than previously.

The scholarships offered are as follows:

(b) A two-year course covering work in a number of the following subjects: Language, Mathematics, Physics, Chemistry, Metallurgy, Electricity, Marine Engineering, Naval Architecture or allied subjects in an approved university, technical school or institute.

(c) A one-year course covering similar work in several of the above subjects in an approved university, technical school or institute.

(d) A home correspondence school course in an approved

correspondence school or a course of thirty-six weeks in the Industrial Y. M. C. A. Evening Preparatory School of the city.

Candidates for scholarships are required to be American citizens and not less than seventeen nor more than twenty-one years of age. Appointments are based upon general conduct, workmanship, character and ability. Scholarships (b) and (c) are granted only to apprentices who have served approximately two years of their time. Scholarship (d) may be awarded after one year of apprenticeship.

The expenses of these scholarships are borne by the company; these expenses include fees, tuition, subsistence, books, instruments and an allowance for traveling expenses. The apprentice is required to serve in the works of the company during vacations, for which services the regular rates of pay for apprentices are in effect.

The granting of scholarships to the apprentices has not created discontent among the boys who are not thus recognized, but, on the other hand, it has had the effect to stimulate them in their efforts. Applications are numerous in a number of the trades, particularly in the electrical and machinist departments, in which there are more applications than can be accepted.

It is not a difficult thing to show an ordinary boy of ambition who is undertaking a trade that it is very honorable and creditable to become an expert mechanic in his chosen line. Such mechanics are comparatively rare, and a boy can feel great pride in knowing that his skill is such as to win commendation and single him out as of note.

Apprenticeship in foundry work has not been very popular, but an endeavor is now being made to show the excellent opportunity which this offers.

The apprentice school work is so adapted and arranged as to assist the boy in shop work, especially in drawing, mathematics, physics and chemistry. This school work is required of each boy, beginning immediately after his six months of probation and continuing for three years, excepting for the summer vacations. Each boy is required to attend two sessions of three hours each, weekly. The time spent in this school work counts on his apprenticeship and is paid for at the regular apprentice rate to which he is entitled.

The correspondence scholarships are especially adapted to young apprentices, as they entail night study, which is no hardship for a boy working eight hours physically, or only five hours during the days on which his school session comes.

The interest of the boys in shop work and school work at the yard is such that, when necessarily left to carry on in the absence of the instructor, they do this without disorder or lack of application. The apprentices have adopted a Constitution of Apprentice Government for the purpose of promoting a helpful feeling toward each other, an apprentice spirit, the business interests of the apprentices and the attainment of greater opportunities for future apprentices of the company. The working body of this organization is the Apprentice Council, composed of ten active representatives elected from departments or groups of departments in the yard. An honor system has been adopted by the apprentice body. This is an innovation among the apprentices, but it promises to function admirably.

Evening schools are conducted under the educational director of the Young Men's Christian Association. An Educational Committee composed of influential men of the town and officials of the yard meet monthly to advise and assist in the work.

An Apprentice Athletic Association, with annual dues of five dollars, handles the athletic activities of the boys. The dues are budgeted to the various sports. The supervisor and his assistants handle the receipts and disbursements. Championship teams in basketball, baseball and football are arranged. During this season the football schedule calls for games with high schools, colleges and with one college

varsity team. No games other than with school teams are scheduled. Stress is laid on clean sportsmanship which is recognized by the various schools with which games have been played.

A band of several pieces has been organized and a glee club has been formed. A bulletin is issued each week to which the apprentices contribute news items of events of interest.

We believe that the organizing of apprenticeships in trades, with scholarships and night schools, can be successfully handled by any yard and become a paying investment in addition to training up young men of character, who will become useful, contented, influential, service-giving citizens; but this means that the owner, a responsible part of the management and many others in the organization must take a heartfelt interest in the young men. It cannot otherwise be done successfully.

DISCUSSION

This paper was discussed at some length by President McFarland, by Hugo P. Frear, whose discussion of the paper was read by Captain Linnard, by Professor Sadler and by Homer L. Ferguson, president of the Newport News Shipping and Dry Dock Company. Mr. Ferguson made mention of the great improvements, in his opinion, of training the apprentice in athletics as an adjunct to their shop training and as being one of the most important parts of the whole system.

W. M. McFARLAND, president of the Society: I have read Mr. Bailey's paper with a great deal of interest and pleasure. It is the kind of paper that I believe will be productive of great good and he deserves our thanks for presenting us with such valuable information. I am very much struck with the incentive offered to the boys by the provision for courses in technical schools and elsewhere at the expense of the company. I regard this feature of the plan, as outlined by Mr. Bailey, as of the utmost importance. I am also greatly pleased to notice the stress he lays on the honorable and creditable standing of the highly skilled mechanic. The paper is so full of good points that to comment on everyone of them would almost amount to writing another paper, and I will refrain from further remarks except to state again what a pleasure it has been to read the paper and my desire that Mr. Bailey should understand our thorough appreciation.

HUGO P. FREAR, naval architect, Bethlehem Shipbuilding Corporation, Ltd.: There is no one connected with shipyard operation who does not appreciate how valuable an asset the right kind of apprentices are. It cannot be disputed that they have a direct and positive influence in lowering the cost of production besides providing man capital to draw on in the future.

Comments on Aviation—Naval and Commercial

By Captain E. S. Land (C.C.), U. S. N.

ABSTRACT

Naval aviation has been aptly termed "the eyes of the fleet." It is needless to add that any arm of any service is very severely handicapped, if not entirely incapacitated, when it does not have proper eyes to carry on its maneuvers, be they peaceful or militant.

Since the armistice there has been a relatively great change in naval aeronautics. During the war every effort was made to produce aircraft for countersubmarine work and for convoy and patrol duty. This led to the development of large flying boats and non-rigid airships. These types now exist in a fairly satisfactory state of perfection, and attention has been diverted from them to the development of aircraft suitable

for use with the fleet. Fleet aviation requires small and handy combat planes of high performance to be carried with the fleet; planes for scouting, observation, and spotting gun-fire; and torpedo and bombing planes for offensive use against an enemy fleet. The development of these types has been pushed vigorously, and there are actually in existence and in operation today a number of designs which give great promise of fulfilling the needs of the fleet.

Simultaneously with the development of special aircraft for fleet work, the problem of carrying these planes with the fleet has received consideration. In home waters, large flying boats working from harbors and bases on shore have proved serviceable, but in order to carry planes with the fleet, it is necessary either to carry the planes on regular ships of the fleet or on special aircraft carriers. This requires that fleet aircraft be small and compact. It has not only been proven possible but also entirely practicable to launch planes by means of catapults; but it is not yet practicable to provide sufficient deck space for planes to return again to the regular ships of the fleet. This requires that these planes must either be designed as seaplanes to alight on the water or they must alight on the flush deck of an airplane carrier.

Successful efforts have been made during the year to develop a suitable fighting plane for the fleet which is small enough to be handled by ships.

As to spotting and observation planes, experience in the battle and scouting fleets has furnished sufficient information to proceed with the construction and delivery of several types which should fulfill the requirements of the fleet.

The development of a suitable torpedo plane has proven extremely difficult in view of the necessity for obtaining a small and compact plane which will, nevertheless, carry the standard torpedo. Five different types of experimental torpedo planes have been constructed, and several of these types have been tested out not only by the Navy Trial Board but also by the service.

The Bureau of Aeronautics has followed the policy of encouraging design and invention outside the Naval Service, but has taken great care to maintain a sufficiently expert design staff so that the Navy would never be entirely dependent upon or forced to accept only such designs as might be submitted by contractors. In the same way, while the procurement of aircraft is normally handled by contract after competitive bidding, the war showed the necessity for controlling the production of a portion of the Navy's requirements for aircraft and the Naval Aircraft Factory was created and has been maintained in an active, but much reduced, operating status.

So far as the lighter-than-air activities are concerned, we are now on the threshold of development, tests, and trials which will indicate, not only to the United States Navy but to the world, whether or not lighter-than-air in general and rigid airships in particular have a proper place in the naval organization. Not only are the military eyes of the world concentrated on these activities, but also the commercial eyes; assuming that the results obtained by the United States Navy in connection with rigid airships are successful, there is no doubt but there will be a tremendous impetus, both from a military and from a civil point of view, in connection with the development and construction of rigid airships throughout a number of countries in Europe and probably in Japan. There is no denying the vulnerability of this type of war weapon, but at the same time it is practicable to make these ships less vulnerable than they have been heretofore.

The rigid airship operating alone might readily be compared to a battleship operating without a convoy of destroyers. The rigid airship in action would probably be convoyed by combat planes or other types of planes, depending upon the mission to be fulfilled. The great advantages of rigid airships from a military point of view are: Their great radius of action, their high speed, their ability to hover,

their ability to readily obtain great altitude, their ability to receive and transmit information, and their general long-range scouting ability, particularly with regard to coastal patrol. It is believed that they form the means par excellence of antisubmarine patrol. They probably will be the aircraft carriers of the future.

At the present time, a new standard of service acceptability has been set up—a standard which requires that each type of engine demonstrate its ability to withstand a running test of 300 hours at full throttle without any failure of such nature as would force a termination of any flight under service conditions. The work accomplished and the work under way in connection with this matter is of the utmost importance to the aerial strength of the Navy, since it goes far toward eliminating the greatest single source of weakness in our aircraft operation—that is, the delays, the uncertainties, the hazards, and the expense occasioned by power plant failures.

In order to satisfactorily "sell" aviation to the Navy, it is essential that aircraft power plants be made reliable and dependable. To an extent not paralleled in any other form of transportation, the performance and utility of aircraft are measured by the degree of excellence of the power plants available, because the power plant not only propels, but also, in the case of airplanes, is the sole means of support.

"Selling" aviation to the country will be a very simple proposition as soon as it can be reasonably shown that aviation does not involve undue risk of life and property. It is a matter of interest to note in this connection that records collected in England indicate that the greatest percentage of passengers, by nationality, who use commercial aircraft flying to and from London is American.

The greatest crying need of commercial aviation at the present time is satisfactory legislation on the statutes of the Government which would control the rules of the air, the inspection, construction, and operation of aircraft, and instruction of aircraft personnel. Commercial aviation since the end of the war has had very difficult sledding financially. There is a nucleus of commercial aviation in existence in this country which deserves the earnest support of the country. As a nation, we have always been strong to protect infant industries, and certainly there is no better way to apply this protection than to lend financial assistance to commercial aviation throughout the United States.

DISCUSSION

PROFESSOR WILLIAM HOVGAAARD, of the Massachusetts Institute of Technology: Captain Land's paper has the rare merit of giving a sober and objective description of the present status of naval aircraft and affords a good basis for judging of the capabilities of this new weapon. In spite of the conservative tone of the paper—or perhaps just because of that—one is impressed with the great possibilities of aircraft in naval warfare. In order to form an opinion of the strategic value of aircrafts, it is necessary to consider primarily long continued war service under ordinary service conditions and, in doing so, we must on the one hand reckon with an average performance of aircraft far below the optimum but, on the other hand, we are justified in assuming that airplanes will be present in future wars in vastly greater number than at present, according to the resources of the respective countries.

(1) *Limitation of Airplanes.* As pointed out by Captain Land, the power plant is yet far from reliable. Planes are very dependent on weather conditions. They are fragile and vulnerable and navigation is often difficult and uncertain. In actual war service, and considering all conditions of wind and weather, the airplane is on the average a short range and uncertain weapon as compared with destroyers and submarines.

(2) *Coastal Service.* In coast defense it is probably safe to reckon on an effective range of airplane up to about 100 miles from shore more or less according to circumstances. If a belt or lane of some 50 to 100 miles can be kept under actual surveillance of planes at all times, it will permit the coastwise trade to be carried on in relative safety and will render a close blockage practically impossible. Landing of troops in force on an enemy coast can only be carried out with any prospect of success, if it is possible to establish command of the air at the point of landing.

(3) *Operation in Narrow Seas.* The passage through straits, such as those at the entrance to the Baltic and the Black seas, will be rendered dangerous in the presence of an active enemy bordering on the coasts of such waters. It is conceivable that under certain war conditions England may be forced to direct the main traffic to India via the Cape route.

(4) *Naval Stations.* The safety of naval stations may be strongly affected, favorably or unfavorably, according to their location. Detached naval stations, such as Pearl Harbor, the Canal Zone, Aden and Singapore, distant from any possible enemy base, will gain in defensive strength, if they are well equipped with airplanes, while, on the other hand, a station situated as Malta may, under certain war conditions, become entirely unsafe as a port of refuge.

(5) *Service of Airplanes on the Ocean.* Airplanes, due to their short effective radius, cannot operate independently over the sea except in close vicinity to the coast where they have their base. In order to operate over the wide expanse of the ocean they must be carried by and based on ships. Such carriers cannot by themselves secure permanent control of the ocean or any part of it.

(6) *Conclusions.* Airplanes in the present stage of development appear to have their greatest value as a means of coastal defense, although in actions between ships they may achieve great results when used offensively. The advent of aircraft is of special benefit to the United States since this country, with a well-developed coastal air defense and a strong navy, can be made practically impregnable. It is of particular importance in the defense of Hawaii and the Canal Zone. Aircraft may also be of great benefit to the British Empire in the defense of its vast and scattered parts. As regards England herself, the insular position is an advantage in defensive warfare but the immunity from attack which could formerly be obtained by supremacy at sea is lost forever.

MASON S. CHASE, naval architect, spoke most interestingly on the commercial importance of aviation. Mr. Chase also made reference to the very vital matter of the effect of aviation upon the morale of the crews of naval vessels. Captain Westervelt and Admiral Taylor also discussed the paper and gave interesting sidelights upon it from the naval point of view.

Some Factors Affecting the Economy of Operation of the Lake Freighters

By Professor Anders Lindblad

This paper is published on page 764 of this issue.

DISCUSSION

HUGO P. FREAR: It has been recognized for many years that the bulk-cargo traffic on the Great Lakes is in a class by itself. In no other restricted territory are such vast tonnages moved. Transportation on the Great Lakes is cheaper than in any other part of the world in spite of the short season and limitation in draft. A fact that is brought out most convincingly is that each size of vessel has a certain speed which will produce the greatest return from the investment for various freight rates and coal prices.

W. W. SMITH, chief engineer, Federal Shipbuilding Company: The author's conclusion, that steam turbine and Diesel installations are not practicable in Great Lake vessels does not seem to be well founded. A properly-designed turbine installation for the larger powers should cost less and have a less fuel consumption than reciprocating engines. It would seem that turbines should not be dismissed entirely without further consideration. I also think it would be unwise to put aside the oil engine as unworthy of further consideration. It is true that many current designs of oil engines are very heavy and expensive but the oil engine is developing rapidly and the engine of the future may be very different from that of today.

REAR ADMIRAL D. W. TAYLOR, former chief constructor of the United States Navy: The paper brings out in a remarkable way the influence of the cost of power upon profits. The cost of coal is beyond the control of the naval architect but evidently the speed to be obtained and the power required to obtain it, both more or less controllable features, are important factors in the equation.

Lake freighters as they stand are handicapped in several ways with respect to speed as compared with ocean-going craft. With limitation to shallow draft, their lengths are excessive. Owing to the great lengths and low speeds of lake freighters, their speed-length ratios are very small indeed, but, in spite of their abnormal frictional powers, their residuary resistance—mainly wave making, seems rather high. The block coefficients of these vessels are very high as compared with those of sea-going craft, but this does not mean much for parallel middle body vessels of great length.

It seems that it is these slow full vessels that need most and repay best thorough experimental investigation of propulsive efficiency.

So far as I know, self-propelled model investigations for these vessels have not yet been made. A very modest expenditure for this purpose would, I am convinced, result in a further material reduction in the astonishingly cheap cost of transportation of bulk cargoes on the Great Lakes.

President McFarland also expressed appreciation of this paper as dealing with the commercial side of engineering as differentiated from the purely scientific or engineering side.

A. E. F. Robertson of the Munson Steamship Company and finally Professor Sadler also made remarks relative to the various lines of thought suggested by the paper and dwelling upon its value as a contribution to the literature of the subject treated.

Wetted Surface

By Henry H. Schulze

This paper will be published in a later issue. As published articles on the subject of wetted surface are generally an attempt to devise a fairly capable method to cover all types of vessels with the attending result that the accuracy on particular types of vessels is thereby impaired, this paper embodies a complete investigation of the subject for one particular type of vessel—a merchant cargo ship of comparatively full form.

DISCUSSION

REAR ADMIRAL D. W. TAYLOR, U. S. N.: As an ancient worker on the matter of wetted surface I want to bear testimony to the value of this paper and the great amount of work required to obtain the results of which Mr. Schulze has given us the benefit. I recall none published on wetted surface comparable with it. Accurate calculations of wetted surface are laborious and monotonous and those of us who deal with them should be grateful to the author for lightening our labors.

Professor Sadler also complimented the author on his work.

Propeller Design Based Upon Model Experiments

By Rear Admiral D. W. Taylor (C.C.),
U. S. N. (Retired)

ABSTRACT

It need hardly be said that when we utilize the results of model experiments in the design of full-sized propellers we rely primarily upon Froude's Law of Comparison, which is now generally accepted by naval architects and marine engineers. Fortunately, in dealing with propellers we find that for a given slip ratio kept constant as speed and revolutions increase, the torque and thrust both increase substantially as the square of the speed or of the revolutions, efficiency remaining unchanged. We may call this for convenience the Law of the Square. If as we increase speed with constant slip the motion of the water relative to the propeller remains the same, we know that the Law of the Square must always apply exactly. It seems hardly likely, however, that this relative motion will remain exactly the same for all speeds. In stream-line motion pressures caused by the motion of an object through the fluid vary as the square of the speed, and the velocities resulting from these pressures as the speed. But the question whether in water, where stream lines are not perfect the Law of the Square is followed sufficiently closely for practical purposes needs experimental confirmation.

It is evident from Froude's writings that he had satisfied himself of the accuracy of the Law of the Square.

Of course the Law of Comparison is quite independent of the Law of the Square. Wave-making resistance of a ship, to which the Law of Comparison applies, does not follow any such simple law. But the Law of Comparison itself cannot apply exactly. It may be stated by saying that at the same slip at speeds proportional to the square root of the ratio of linear dimensions torque and thrust of model and full-sized propeller vary as the cube of linear dimensions. But for liquids the exact Law of Comparison requires that model and full-sized propellers should work under heads proportional to linear dimensions.

This is not the case for model and propeller in practice. The model works under a head equal to its submergence plus the pressure of the atmosphere. The propeller works under a head equal to its submergence plus the same atmospheric pressure. The result is that, though a full-sized propeller may break down through cavitation, its model at corresponding speed, working under relatively a much greater head, does not break down correspondingly, and the Law of Comparison does not apply. Fortunately, we need seldom apprehend cavitation, and the fact that the Law of Comparison fails when it is present does not seriously reduce its value in enabling us to utilize in full-sized designs results of model experiments.

Accepting the proposition that the Law of the Square and Law of Comparison apply to propellers with accuracy adequate for practical purposes, we are still to consider the fact that when driving a ship the propeller is working in water disturbed by the ship, and hence under conditions not strictly comparable with the model if tested apart from the ship, in undisturbed water. This difficulty is overcome by testing the model propeller in its proper place behind the ship model, thus reducing the discrepancies of condition to minor factors, but before considering this branch of the subject let us consider facts established by model experiments for propellers working "open," i.e., apart from the ship.

A cardinal advantage of the model experiment method is that it enables us to test the effect of varying one only of the many factors affecting propeller action. When this is done on a fairly comprehensive scale we find that many past ideas as to the actual and relative importance of these factors are erroneous—some of them grotesquely erroneous.

There are still designers who attach much importance to disk area ratio and figure its effect upon efficiency regardless of other factors, usually assuming that the lower the disk area ratio the greater the efficiency.

So far as can be determined by model experiment, which is the only practicable method of investigating this factor apart from others, it is evident that such ideas are erroneous. Efficiency first goes up and then goes down as we increase disk area ratio from 0.2 or so, the best disk area ratios as regards efficiency being somewhere over 0.3, though the variation of efficiency with disk area ratio is practically negligible over a wide range on either side of that for maximum efficiency.

Perhaps the most notable fact shown by the model experiments is the great effect of blade thickness upon efficiency of model propellers—a fact practically ignored until these experiments, published in 1910.

It is almost universal practice to use blades of generally elliptical outline as developed. No merit has ever been found in freak outlines, nor do I know of any experiments or experience showing that any outline is appreciably superior to the elliptical. The question is essentially whether we should use broad or narrow tips.

We seem justified in concluding that blade outline, as long as it is smooth and fair, is a very minor factor in propeller performance, and, all things considered, the standard elliptical outline deserves to be the standard. However, for single-screw vessels where the screws must work with very high actual slip, broad tips are frequently indicated. Their larger power absorption capacity enables them to work at less slip, and the gain of efficiency associated with reduction of slip is liable to overcome the loss due to blade outline. The gain is small in any case, but worth going after when we are forced to adopt objectionably small diameters.

Efficiency is one of the two principal things we need to know about a given propeller. The second is the absorption of power.

The advantages of basing propeller design upon results of model experiment result, broadly speaking, from two sets of facts.

In the first place, by model experiment we are enabled to classify the various factors involved in propeller performance in the order of their importance, eliminate the non-essentials, subordinate those that are secondary, and determine quantitatively the influence of the only primary factors, namely, diameter and pitch. The secondary factors I would put mean width ratio, giving blade area, and blade thickness fraction, giving blade thickness. These are so secondary that by determining diameter and pitch from standard diagrams of average mean width ratio and blade thickness fraction, we obtain results that would be little changed by any likely changes in blade width and thickness.

In the second place, when we base our designs upon results of model experiments we naturally consider separately the individual factors involved, the propeller itself, the effect of the ship upon its action, and the effect of its action upon the ship. We are not yet in a position, without specific model experiment, to assess quantitatively with minute accuracy all the individual factors. But we are able to approximate to them and to consider, examine, and appraise these factors separately is essentially a sounder method than to lump them. No method of propeller design can be sound that ignores essential factors. It is obviously much more difficult to consider them lumped than separately. By model experiment only is it practicable at reasonable cost to appraise the various factors involved.

Now what of the other side? What are the objections to basing our designs upon model experiments? There is only one—the possibility that Froude's law may not apply and that the performance of full-sized propellers cannot be accurately inferred from tests of their models.

The performance of model propellers is appreciably affected by bluntness of blade edges, and there is no reason to

believe that this is not also true of full-sized propellers. If we consider it necessary for structural or other reasons to fit propeller blades with rounding edges, we should remember that this involves some reduction of efficiency and increase of diameter as compared with propellers derived from the Standard Series sharp-edged models.

There is also the question of thickness of blade sections. Rather a startling increase of efficiency is shown as blades are thinned to about one-half the customary thickness. This is a result not about to check with full-sized screws, but there happens to be one rather remarkable test that fully bears it out. I quote from my discussion in our Transactions for 1905 on Curtis and Hewins' paper.

"Some experiments made more than twenty-five years ago by Mr. Yarrow shed great light upon the effect of thickness of propeller blades. Mr. Yarrow tried twenty-five different screws upon a single-screw torpedo boat. Most of the screws tried were two-bladed and two were identical in every respect except that one was made with blades as thin as possible. The thin-bladed screw showed a very marked superiority to the thick-bladed screw.

"The maximum power which could be delivered with the latter was 350, and the corresponding speed for this boat 17.4 knots. The thin-bladed screw when absorbing 350 horse-power gave a speed of 19.15 knots, a gain of $1\frac{3}{4}$ knots, or almost 10 percent in speed, simply through a change in thickness of the two blades. The thin blade was so thin that it took a permanent set when more than 350 horsepower was put through it. * * *

To sum up and speculate to some extent, it would seem reasonably certain that if we could make propeller blades without thickness, Froude's law would apply to model and propeller virtually exactly. Taking propellers as they are, it probably applies substantially exactly to propellers with fairly broad, thin, sharp-edged blades. As we narrow blades, thicken them and make their edges blunt, we are liable to get more and more departure from Froude's law. The question, of course, arises: What difference does it make?

If we are designing propellers following closely the blade section features of the Standard Series, we can expect the full-sized propellers to follow closely Froude's law and use the diameter given by the diagrams. If our blades are thicker, narrower, and blunter than the blades to which the diagrams apply, but the tip speed low, we will discount any probable departure from Froude's law by using diameters and pitch ratios 2 percent or 3 percent greater than given by the diagrams. If, furthermore, tip speed is rather high and we are approaching, though short of, cavitating condition, we may well provide a slightly larger margin of diameter and pitch ratio—say up to 5 percent.

The above applies to the ordinary propeller of commerce with blades of ogival section. As regards freedom from cavitation and close adherence to Froude's law, this section leaves much to be desired. Unfortunately, it is not practicable with apparatus available in the ordinary model basin to test the cavitating qualities of blades of propellers of normal pitch ratios. Otherwise there is little doubt that for high-speed propellers we should long since have developed sections superior to the ogival.

DISCUSSION

CARL E. PETERSEN, naval architect, United States Lines: With reference to the matter of blade thickness, the performance of a large number of full-line cargo ships has shown marked improvement when bronze wheels are substituted for cast iron. The thickness of blades in such cases has been reduced 25 to 35 percent and it would seem that thinner blade sections are advantageous on such vessels. It would appear that more consideration should be given to the use of bronzes of 95,000 to 100,000 pounds tensile strength instead of manganese bronze having about 65,000 pounds tensile strength. Propellers of such metal are actually in service and have given excellent results.

E. A. STEVENS, JR.: I agree with what Admiral Taylor

says about blade outline, provided there is room to swing a propeller of proper diameter, but if this is not possible considerably more can be gained by broad-tipped blades than Admiral Taylor seems to think. I have had experience with ships where there was not room for a propeller of sufficient diameter and have been able to improve their performance considerably by replacing wheels having approximately elliptical blades by those with broad tips. In one case the coal consumption was reduced about 10 percent with about a knot increased in speed but all the saving cannot, however, be credited to the propeller as the engine was able to operate under better conditions with the new wheel than with the old.

While there is unquestionably a loss in efficiency from blunt blade edges, I believe the following edge has more effect than the leading one.

I do not think that blade thickness, unless it be abnormal, has as much influence upon efficiency as Admiral Taylor appears to.

W. W. SMITH: In designing a propeller it is of course desirable to use the pitch, diameter, revolutions per minute, form and area which will give the highest efficiency for the data and conditions given. In my opinion it would be most convenient to have the best or optimum value for the various numbers and forms of blades plotted on one chart. Where best values are used, such a chart would in many cases suffice for design. Where conditions make it necessary to depart from the best values R. E. Froude's chart, given in his paper before the Institution of Naval Architects in 1908, should be used. Thus, only two charts would be required for solving all problems.

REAR ADMIRAL C. W. DYSON, U. S. N.: I agree entirely with Admiral Taylor in his conclusions as to the applicability of the law of comparison to propellers within certain indefinite limits.

Admiral Taylor criticizes the lumping of the propeller-hull loss factors as being unsound. All guessing is unsound, but, where we are driven to guess, the percentage error resulting from one guess would be less than that resulting from the summation of errors in several. Where the vessel is an important one, the power high, and the hull of such form as to produce heavy losses due to obliquity of flow of the water to the propeller, the wise man will always check his estimate of the performance by trial of the self-propelled model.

Personally, I am of the opinion that there is a very close relation between the Taylor and the Dyson methods of design and that by a little investigation the two methods could be combined into one.

The Probable Effect Upon Ports of the Probable Growth of Ships

By Commander John H. Walsh (C. C.),
U. S. N. (Retired)

This paper will be published in a later issue.

DISCUSSION

JOHN H. BERNHARD: I have always felt that ports are at the mercy of the trend of the times and that ships built in accordance with these will always dictate the conditions of the port.

SAMUEL YOUNG, chief engineer of the Port of New Orleans: Commerce is growing by leaps and bounds and millions upon millions are being expended for ships and for the development of ports. It does not follow that because a certain stage of development will be demanded ten, twenty or thirty years hence, great sums should be expended for arriv-

ing at these results immediately. On the other hand, future building, both of ships and ports, should not be haphazard and without regard to ultimate limitations.

MAJOR LANSING H. BEACH, chief engineer, United States Army: I am not prepared to agree with the view expressed or implied, that in the long run ships will not be limited in growth by the accommodation in ports. Even assuming that the economics of water transportation should tend to produce an indefinite growth in the size and draft of the average cargo ship, the question of whether the ports of the world as a whole will so increase channel depths as to permit the construction and operation of such great ships is wholly a quantitative one based on relative costs and savings. Moreover there is no present indication that the ordinary cargo ships will in the near future attain dimensions at all comparable to the few very large vessels of the type illustrated in the paper. The present tendency is for the ordinary cargo ships to increase in size but by no means to approximate to the small group of exceptionally large vessels now confined principally to the liner trade between New York and certain European ports.

MAJOR JOHN W. M. BLACK, U. S. A. (Retired): I would suggest that a better title to a paper of this kind would be "The Probable Effect of Ports on the Future Growth of Ships" for really the ultimate controlling factor must be the dimensions of the channels leading to the ports and the capacity of the ports to absorb and supply cargo. The increase of the depth of ports is not impossible but the cost of such an increase is so great that in most cases the annual interest on the investment required for the work would exceed the savings to be effected by the use of the deeper and longer vessels. Port improvements are more and more becoming public works with expenditures made from public funds and it is essential that they be economically justifiable. Increase of channel dimensions and of port capacities should be made only when their cost is demonstrably less than the savings to the public which such increases would produce.

CAPTAIN F. T. CHAMBERS (C. E. C.), U. S. N.: I do not think that too much weight should be given to diagrams based upon the largest single ship of succeeding years. Of course it is a fact that smaller ships have a marked tendency to become larger ships but, with the exception of the passenger liners of the so-called Atlantic ferry, and a more limited number of oil and ore cargo ships plying between fixed ports, where special facilities have been built to accommodate them, there is almost none which exceeds in draft the limit set (32.2 feet) in the proposed resolution of the 1912 International Congress.

PROFESSOR WILLIAM HOVGAARD: The question raised is one of mutual action and reaction between ships and ports and it is difficult to say which is the stronger. In any case, it is certain that the moving force comes from the ships and this I believe is due to the fact that there is a steady growth in the world's trade and more particularly in the ocean-borne trade of the United States. Just so long and in the same measure as the expansion continues of the world's trade and therewith of its sea-borne commerce, just so long and in the same measure will merchant ships of increasing size be able to obtain full load of freight and passengers.

As regards warships, I believe that if no artificial restrictions were imposed, their displacement would still go on increasing.

CARL E. PETERSEN: Taking into account the numerous factors to be considered, there is probably a limit of size of passenger vessels which cannot be exceeded but I venture to say that in all probability the thousand-footer will be the largest vessel that port authorities will be called upon to provide facilities for, a vessel of this length becoming a reality only with economic conditions favoring it, which is not the case at present and probably will not be in the immediate future.

It was pointed out by Captain Land that the adoption of Diesel engines might have some effect on the future size of ships and by Professor Sadler that in any event economical development could not in the long run be restricted or limited by legislation.

The Economics of Transatlantic Liners of Various Lengths

By Carl E. Petersen

This paper is published on page 759 of this issue.

DISCUSSION

REAR ADMIRAL D. W. TAYLOR: Mr. Petersen, upon certain basic assumptions, has developed in a logical way the results to be expected from mixed-type vessels of various lengths and corresponding displacement. He explicitly states that his work applies to existing conditions and I want to emphasize that fact because a change in basic conditions changes entirely the conclusions. When one looks at a diagram showing the steady increase of length and displacement for transatlantic liners for seventy years past it rather compels a belief that the change of conditions in the future as in the past will favor the large vessel. It is sixty years since the *Great Eastern*, nearly 700 feet long, in the day of 300-foot liners, was a financial failure, but the 700-foot liner has now been with us and successful for some twenty years or so. For the purpose of the author he was fully justified in assuming that the passenger performance falls off with the length of vessel but is that necessarily the case? It may be for the type discussed in the paper where the 1,000-foot vessel makes less than 24 knots but, if the vessel were built to take advantage of her exceptional length by showing exceptional speed, it seems certain that her passenger performance would improve most decidedly.

I believe that if we can judge the future by the past the growing North Atlantic passenger travel will be accommodated by ships averaging longer and larger than present optimum lengths.

WILLIAM T. DONNELLY: Too little consideration has been given to the load factor; that is, a larger ship would pay, if she could be consistently and continuously loaded to capacity and it is quite apparent, as pointed out in this paper, that our ships of maximum dimensions have passed beyond this possibility.

Machinery Trials, Coast Guard Cutter Modoc

By Captain Q. B. Newman, Engineer-in-Chief,
U. S. Coast Guard

This paper will be published in a later issue.

DISCUSSION

Mr. C. P. Wetherbee, who had officially represented the Society of Naval Architects and Marine Engineers on this trial, made a report, drawing attention to the fact that he was merely an observer and, furthermore, that the trial confessed to be simply an attempt to obtain accurately essential facts and that no conclusions in regard to the particular type of machinery under test were drawn.

CAPTAIN ELLIOT SNOW, (C. C.), U. S. N.: It is not often that an official occupying the position of Captain Newman can find the time to lay out and then personally supervise trials of this character. That this was the case in the present instance lends added weight to the data recorded in the article.

I would like very much to see added to this article the combined generator and motor torque curves during reversal for which this installation was designed. These would help in arriving at an adequate explanation of the difference in performance between backing trials Nos. 1 and 2: I would like to get the views of the author, or some other propeller expert, on the following point: Will a propeller under such conditions absorb full power and correspondingly check the vessel from going ahead, or will it simply churn the water for an appreciable interval and thus nullify to a large degree the advantage of full backing power that is claimed for electric drive?

T. B. STILLMAN, Babcock and Wilcox Company: For the forced draft run No. 7 it was a relatively easy matter to obtain steady conditions in the fire room. On the contrary, during the natural draft run the course of the ship was changed several times, this affecting the available draft at the boiler uptake by nearly 100 percent on account of the variation of the direction of the ship with respect to the wind. As the amount of oil which could be burned is directly dependent on the draft available, it was necessary to vary the oil pressure from 165 pounds to 270 pounds per square inch in the effort to keep a satisfactory balance between the air being drawn through the burners and the oil being sprayed through them. This marked fluctuation in the rate of feeding the air and oil caused very natural fluctuations in the rate of flow of feed water and the pressure of steam coming from the boiler, both of these conditions being detrimental to best efficiency results.

In addition to the unsatisfactory operating conditions indicated, it should also be kept in mind that through the open fire room existing during natural draft operations there is a larger loss from the boilers due to radiation than when the fire room is closed. Thus, if the operating conditions existing during both tests are thoroughly understood, it can be appreciated how the large difference in efficiency between the two tests was secured.

Taking the trial results of the boiler as a whole, I believe we could safely say that the results are satisfactorily consistent in view of the conditions under which the tests were run as compared to those usually obtained when boiler test data are secured.

Aside from the immense value of Captain Newman's paper to the marine engineering profession in general, I feel it is of particular interest from a boiler operator's point of view, as it is very unusual to obtain as complete results from boilers operating under service conditions, as were obtained during these trials.

W. W. SMITH: Special attention is called to the rapid increase in fuel consumption below the full speed. This is due principally to insufficient blading in the turbines to absorb the energy in the steam efficiently at reduced power. It is a common fault in marine turbine installations. There are eight impulse stages in this turbine. Cross-compound turbines as used with gear drive usually have considerably more blading.

The auxiliary steam consumption, exclusive of excitors, is larger than usual on merchant vessels and seems rather excessive for an installation of this kind.

The steam consumption of the exciter unit is 14.5 percent but only about 12 percent is used for the main transmission. Due to utilizing the exhaust from the exciter unit in the lower stages of the main turbine, only about 60 percent of this loss is chargeable to the transmission gear, thus there is about 7 percent loss due to the exciter steam consumption alone which must be added to the loss in the main transmission gear. If we allow 8 percent for the latter, the total loss in transmission will be about 15 percent. This does not compare very favorably with about 3 percent loss for a double reduction gear.

Admiral Griffin, U. S. N., noted the apparent lack of

economy of auxiliaries, particularly that of the electrical units connected with the main propelling motors and stated that it would evidently be advisable to design special excitors for this class of work.

Mr. E. A. Stevens, Jr., and Mr. Maxwell Day, of the General Electric Company, also made some general remarks upon the paper and the value of the data which it contained.

The Manufacture of Heavy Steel Castings for Ships, with Special Reference to Stern Frames, Rudders, Shaft Brackets and Stems

By Hugo P. Frear

ABSTRACT

The general process of making fluid steel for castings is more or less well understood by a large percentage of the members of the Society. Great progress in the manufacture of heavy steel castings for ships in the past several decades has been made towards a reduction in the percentage of losses on account of defects or failure to meet specifications. This is due in a large measure to advancement in the art of making steel, greater attention to design and the location of sink heads, more general use of chill plates; and more careful and intelligent work in the foundry. General foundry practice and the materials used, however, have changed but little. The problem of making steel castings over the above period was well understood. Steel foundry operations of molding, core-making, pouring, etc., are very similar to those employed in the iron foundry. In the early days rolled and cast steel were equally unreliable on account of the poor quality of the product.

The difficulties in making good steel castings are and always will be greater than making iron castings. These greater difficulties are inherent for several reasons. Fluid steel is necessarily hotter, cools more rapidly, shrinks more and contains more gas than iron. On this account it is necessary to give more careful consideration to design, to the preparation of the mold, and to use a more highly refractory sand.

As already stated, the melting point of steel is higher than for cast iron and the shrinkage greater. Both the melting point and shrinkage vary more or less inversely as the carbon content. It therefore follows that the lower the carbon content the higher the melting point and the greater the shrinkage. Low silicon also increases shrinkage. As steel chills more rapidly than iron, this may also be attributed somewhat to the lower carbon content. It may be concluded, then, that a large part of the difficulties in making steel castings as compared with iron is directly due to the lower carbon content.

It is common knowledge that the shrinkage of steel is a variable quantity even in the same casting. This is more evident in long castings. There is no way to accurately estimate the shrinkage to allow at different points of the pattern. A stem casting is one of the most difficult to make so far as predicting correct shrinkage is concerned.

Shrinkage may be affected by variations in thickness and temperature of metal at different points of the mold. The temperatures are affected by thickness and by the way the metal is run in the mold. If the gates are not well distributed, the metal in some parts may be much cooler and almost ready to freeze by the time it has filled the mold. At the thicker parts of the casting the outer layer, next to the mold, chills quickly, while the inner layers are still fluid and hotter. When the second and hotter layer freezes on to the first layer, the latter is stretched, because there can be

no sliding between the two layers and then the shrinkage is less than it ought to be.

Steel is said to shrink about $\frac{1}{4}$ inch to the foot, but in practice frequently varies from $\frac{1}{8}$ inch to $\frac{1}{4}$ inch per foot.

Many of the members of this Society can look back to the time when stern frames, rudder frames, and stems for merchant steamers were almost exclusively forged of iron. Both steamship lines and builders were slow to change from iron forgings to steel castings.

It is a mistake to believe that internal stresses or serious defects do not occur beneath the surface of heavy iron forgings, especially if made of material of doubtful quality. Broken posts or shoes have occasionally revealed these defects.

Under the great building programs of the war, iron forgings in quantity were impossible. The art of making these forgings required greater skill than could be created for emergency war work. Not only were the plants equipped to make such forgings of small capacity and few in number, but good iron was practically unobtainable. The increasing use of cast steel and scarcity of good iron scrap offered little inducement for plant extension or for younger men to take the places of those who had grown old at the forge. Even most of these older men, like Othello, lost their occupation during the war and have disappeared. Iron forging, therefore, on account of the diminishing demand before the war, followed by the almost exclusive use of cast steel, has practically become a lost art.

Before the design for a large and especially a complicated steel casting is finally approved the traffic man, patternmaker and molder should be consulted. Shipping facilities and clearances in tunnels and under bridges frequently necessitate making the casting in several parts or the elimination of foundries less fortunately located in this respect.

The designer, patternmaker and molder should have a thorough knowledge of shop conditions, shipping facilities, and the difficulties previously encountered on work similar to that in hand. The patternmaker and molder should be acquainted with the action of the fluid steel in filling the mold, and in cooling so as to anticipate and guard against eventualities which experience only can predict.

In laying out the castings, simplicity should be kept in mind. Abrupt and sudden changes in shape, sections and masses should be avoided to the greatest possible extent. Where comparatively large masses of metal cannot be avoided they should be well tapered off into the thinner sections. Large fillets should be provided at all flanges and intersections. Flanges and webs or ribs should be designed with proper draft to facilitate drawing the pattern and pulling out the drawbacks.

Experience has indicated that castings frequently come out over-weight unless steps are taken to prevent it. To offset this, castings, in which weight saving is important, have deliberately been drafted lighter than specified. In recent cases, parts have been designed from $1/16$ to $1/8$ inch under requirements, according to thickness, and on being checked found to meet specifications.

Although the designer may have consulted the patternmaker and molder before issuing the plans, it is often customary for the patternmaker and molder to consult freely during the construction of important patterns. The foundry should receive the first consideration in deciding upon the methods of molding and the best type or construction of the pattern for performing the work. It is false economy for the patternmaker to try and save a little money on the pattern at the expense of the foundry.

After the patternmaker and molder have agreed upon the type and method of making the pattern they should jointly estimate the shrinkage which may vary somewhat at different points.

If patterns are shipped any distance, they should be

properly braced and checked before shipping and again checked at the foundry.

The facing sand used in making the mold and cores must be capable of resisting the high temperatures without fusing and sticking to the casting or spalling. It must be porous to facilitate the escape of gases generated in the steel while cooling, or by contact with moist sand. Gases trapped in the metal result in blow-holes. There must be sufficient cohesion for ramming and stability for retaining form under the ferrostatic pressure of the molten metal.

An ideal sand, in order to possess the greatest possible permeability for the escape of gases, should be composed largely of grains of uniform size and of smooth, well-rounded form. It is obvious that a sand of this ideal character would not possess the necessary cohesion to retain its form without the addition of some finer material for a binder. It is also obvious that the smallest possible quantity of binding material should be used to give the greatest permeability. With the exception of a small amount of burnt sand, used only for economy, new materials should be employed.

Pure silica or crushed quartz sand (from 95 to 98 percent silica), mixed with a little burnt sand and core compound or clay, approximates these requirements. For large castings the facing sand is from 1 to 2 inches thick, according to the thickness of metal.

There are comparatively few cores used in the manufacture of the large steel castings included under the title of this paper which present as serious problems as those frequently encountered in designs requiring cores of greater area and length.

Effective venting in cores is more important even than with the mold itself. The mold surrounds the casting on the outside, and the gases have more freedom to escape outward through the sand than inward through the cores.

Flasks are boxes or containers which hold and support the sand forming any part of the mold. Cast iron, cast steel or rolled steel, on account of their durability and strength, are exclusively used in making up flasks for large steel castings. Some steel castings for ships are now so large and require such deep flasks that entirely new sections or complete special flasks have to be made.

The several types of large steel castings for ships are so different and the variety of design for each so great that a detailed description of the foundry practice for every case would be out of the question. There is a most excellent series of articles describing actual examples of molding heavy steel castings for ships in *Foundry*, Vol. 47, 1919, by Ben Shaw and James Edgar, and, for those interested, would well repay reading.

Pouring should be done as early as practicable after the mold is fitted up before it has had time to absorb moisture, and preferably while it is still warm. The getting ready of the ladles and the final adjustment of the heat should be timed for this event.

Sinkheads, risers or feeders, as they are sometimes called, may be termed a necessary evil in the production of sound steel castings. The large percentage of scrap in the sinkheads and the expense of cutting them off is one of the important items in the cost of steel castings. The main function of sinkheads is to increase the ferrostatic head in the mold and feed fluid metal into the shrinkage cavities, created during contraction.

It requires good steel and good foundry practice to produce sound castings, but these are not sufficient to guarantee uniformly good results when, on account of the design, nothing short of a miracle will do the trick.

If the design is such that the lighter sections are at the bottom and the pouring is done slowly from the top, the conditions would be ideal. The cooler metal and first chilling would be at the bottom and gradually work upward. Shrink-

age cavities or pipe during contraction formed first at the bottom would be fed from the casting and also gradually work up to the top where the final feeding would come from the sinkhead.

In the manufacture of steel castings there is unfortunately a large percentage of rejections on account of defects. It might not be an exaggeration to say that the closest scrutiny might reveal minor defects, more or less important, in almost every large steel casting. The foundryman can, however, take some consolation from the fact that many of these can be salvaged by electric welding or other means.

The various characters of defects, resulting in rejections, arranged approximately in the order of their importance, are shrinkage cracks, shrinkage cavities or pipes, blowholes, surface imperfections, warping and cold shuts. Shrinkage and gases are, therefore, the chief offenders as far as the more common defects in steel castings are concerned.

Hot metal, sudden changes in thickness, small fillets, sharp corners, quick bends, webs, flanges, internal stresses from uneven cooling, and unyielding molds and cores all contribute to the possibilities of shrinkage cracks.

These most frequently occur between heavy and light sections, in fillets, corners and at bends.

If shrinkage is estimated at $\frac{1}{4}$ inch per foot, the contraction and the necessary yielding of the mold in a length of 24 feet would amount to 6 inches. The distance between the top and bottom gudgeons on the stern frames of many merchant steamers is at least 24 feet. It is therefore apparent, if cracks are to be avoided, that the mold must yield, in this case, about 6 inches between these two points, provided the casting is not stretched in the manner above referred to.

The writer has been informed that probably in the case of 75 percent of ordinary merchant steamers, on, or after, going into commission, small cracks exist either at the top or bottom or at both top and bottom of rudder gudgeons. It is also stated that these are being continually electric welded in dry dock.

Surface defects are usually found on the upper surfaces of the castings. They are caused by loose sand floating to the top and becoming imbedded in the surface of the metal. This loose sand may have been washed off by the running metal as the result of imperfect drying, spalling off of patches, insufficient nailing of the cope and the bottom of sprues on other parts where erosion is excessive. Sand or dirt not thoroughly blown out before closing up the mold will produce the same evil effect. Sand of low refractoriness will soften and burn into the casting. The effect of this will not be limited to the upper surfaces but show over the whole casting.

Warping is generally the result of internal stresses set up by uneven cooling or from sagging on account of not being properly supported in the annealing furnace.

Cold shuts result from cold pouring. If the metal running around cores or from different gates is too cold when the streams meet, they will not make a perfect union. This fault is termed a cold shut.

Steel castings of the kind under consideration are rarely rejected now on account of shrinkage cracks or cavities and blowholes where satisfactory repairs can be made by welding. When electric arc, oxyacetylene or thermit welding were in their infancy, prejudice against them was so general that many of the castings now salvaged would have gone to the scrap pile.

The art of welding has become so well understood that it occupies a recognized place in the steel foundry and for making repairs on vessels in commission. A skilled arc or torch operator should have no difficulty in making a perfect weld. If any poor metal is run in, he knows it and should cut it out. He should not proceed to cover it up.

Large cracks or breaks should preferably be repaired by thermit welding.

Whichever process of welding is adopted, all bad material

and sufficient steel in way of cracks should be cut out so that the parts can be thoroughly preheated and space provided for running in the metal.

Welding metal is run in so hot that a hard crystalline structure extending into the casting results. It is therefore advisable to do all possible welding before annealing. Castings on which important welding has been performed after annealing, or that require machining in way of the same, should be properly annealed again after welding where possible.

The judgment and experience of the manufacturer must be relied upon in deciding the procedure to be followed in shaking out a large casting. This depends on how soon or to what extent it would be safe to subject the individual casting to air cooling and on the practice of the foundry in the construction of the mold and cores in respect to automatic yielding or collapsibility. Too early exposure to the air, in many cases, would aggravate the internal stresses with the probability that either serious cracks or innumerable infinitesimal cracks too small to be distinguishable might be developed.

Cleaning and cutting off of runners, gates, risers, fins and brackets, etc., should be completed and the casting made ready for the annealing pit or furnace as quickly as possible.

All cast steel has a coarse crystalline structure and is subject to internal stresses before annealing. The object of annealing is to improve the texture of the steel by breaking up this coarse crystalline structure, relieve the internal stresses and also soften it for machining.

No hard and fast rules can be followed in deciding when castings should be placed in the annealing furnace. If castings are cooled and thoroughly cleaned before annealing, the welding up of visible defects can be first completed.

With castings of complicated design rapid or uneven cooling might result in cracks at any stage of cooling after pouring. In such cases and where proper facilities exist it would probably be safer to get the casting into the annealing furnace as hot as it can be safely handled.

As a safeguard against sagging or warping in the furnace, the casting should be supported on blocks of small area, spaced widely to allow free heat circulation under the casting, but close enough to avoid too large spans between supports.

There are so many different designs of large steel castings for ships and warping is so erratic that each case of straightening usually presents a special problem. Sometimes the design, thickness of metal and extent of warping admit of cold straightening. In most cases this can be done better and with greater safety under an hydraulic press. In many cases local heating has been resorted to in straightening and taking out twists in castings of simpler design. The temperature of the local heating should not be greater than necessary to accomplish the purpose and should preferably be kept below the annealing point.

DISCUSSION

M. C. HUTCHINSON, of the New York Shipbuilding Corporation: The welding of defective castings will seriously delay our progress toward proper steel making besides presenting unknown dangers. The welding of new steel castings is a makeshift that records failure. Mr. Frear is right in saying that the designer should be kept in touch with the molder in making his designs but too much of the burden of responsibility should not be placed upon the designer for it should be his business to meet the demands of economy by designing castings as light as he can but strong enough and of such shape as to secure the strength with the least weight. Ship castings are frequently designed with twice the weight necessary for strength in order to get a good casting. This is not so important in castings used for buildings and bridges but is a vital matter in ships.

H. E. DILLER, metallurgical editor, *The Foundry*: In this

connection it is interesting to note that after many years of specifying definite limits for the percentages of phosphorus and sulphur allowable in steel some of the leading engineering societies of the country have a joint committee investigating the effect of these elements on different steels. This investigation is of huge magnitude but, when finished, it will be valuable to substantiate the conclusions drawn. It is only by the cooperation of the designing engineer, the pattern-maker and the foundryman that the maximum of success can be obtained.

It seems a great benefit to the industry to be able to weld castings which formerly had to be discarded but the benefit will be reduced, if the ease with which a casting can be welded reduces the interest of the foundryman in producing a perfect product. I would suggest that it would be an excellent thing that, where opportunity permits, further investigation be made in the question of the relation between porosity and the percentages of sulphur and phosphorus.

DAVID ARNOTT, American Bureau of Shipping: My own experience in the survey of ships has convinced me that large cast steel stern frames would require to give better results under the test of operating conditions before they can be considered to be in the same class with forged iron frames so far as reliability in service is concerned. The ship castings produced during the war can be grouped into three classes—good, bad and indifferent—and I am afraid that a large proportion were in the latter category. It is certainly interesting to learn that the art of welding now occupies a recognized place in the steel foundry but I rather think that the production of sound steel castings will never become an exact science, if the foundry is given blanket approval to use welding for the repair of major defects. The place for major welding operations is a drydock or repair shop—not the foundry.

H. F. NORTON, naval architect, Newport News Shipbuilding and Dry Dock Company: We have found so many large castings out of shape in a sidewise direction, where the symmetry seems to preclude the idea that shrinkage is the probable cause of the trouble, that we have come to believe that the matter of adequate support in the annealing oven is worthy of considerable further study.

Fuel Conservation and Engineering Performance Standards by Shipping Board Vessels

By Joseph E. Sheedy

This paper will be published in a later issue.

DISCUSSION

W. W. SMITH: In general the method described is thoroughly practicable and very simple. I consider it the best method I have seen for determining the general performance of a vessel. It should be of special interest and value to ship operators in checking the performance of their vessels and keeping up the efficiency of the engine room crews.

CAPTAIN ELLIOT SNOW, (C. C.), U. S. N.: The author correctly and wisely points out in the summary that the standards given are not absolutely correct. The curves are necessarily approximations and their use is of relative value only. Errors will affect all vessels alike and hence not be averse to a particular vessel of the group. It is to be hoped that the author will be able to supplement this article with curves and performance data prepared for the *Eclipse*, *Archer*, *Invincible* and other vessels of this class both before and after their conversion to electric drive.

R. W. MORRELL, marine superintendent, Tide Water Oil Company: The use of observed miles instead of engine miles as a basis for the unit of measure appears to me to introduce

unnecessary complications. While it is true that the efficiency of a vessel as a whole is the ultimate consideration, it is really the efficiency of the engineering department we are getting at and through which it is hoped to accomplish the real results. It seems to me to be preferable to segregate this engineering efficiency by confining the consideration to engine miles and thus eliminating all such uncertain variables and assumptions as are involved in the condition of the bottom, seamanship, the skill of the helmsman and the effect of currents. Suppose a ship does fall short of her theoretical miles per ton, no one can say definitely whether it was because the ship was kept bucking into a head sea instead of easing off a little and making more mileage with less labor or whether the fault lies in some adjustment of burners or links. There is some question in my mind about the basis of the correction factor applying to shaft horsepower for various depths of loading. I believe a more rational basis for applying the correction would be simply on percentage of the full load draft, leaving out the beam entirely. It is noted that the trim of the vessel has not been taken into consideration and this leads me to wonder whether certain factors are not carried to too great a refinement while ignoring others of equal importance. Improper trim is a serious handicap to any vessel, both as to propulsion and steering qualities. I am sorry Mr. Sheedy did not go further in his paper and describe the methods used in making practical applications of the data obtained, as I find this to be the most interesting part of the problem. Knowing a ship to burn too much fuel, what are we going to do about it? It is only by careful study of log abstracts and indicator cards, as well as inspection and by a process of elimination that the real trouble can be located. I must say that the work of the committee impresses me as most admirable and I would strongly urge that private shipbuilders and operators adopt similar methods.

Some Considerations on the Conversion of Steamships to Motor Ships

By Robert Haig

ABSTRACT

In considering the question, building motorships or converting steamships to Diesel motor-driven ships, American shipbuilders and shipowners have had a peculiar situation to deal with. The Shipping Board owned and held for disposal an enormous number of ships, most of which had been constructed during the war or immediately succeeding the war, and which were more or less acceptable as merchant ships in the ordinary run of business. Owing to the conditions arising in the oil industry during the latter part of 1922 and the first half year of 1923, a very firm market developed for oil tankers for a time, affording the Shipping Board an opportunity to dispose of probably 60 percent of the then existing fleet of tankers. The number of tankers sold has relieved the pressure on the market for that type of boat, and results have demonstrated the fact that, with a general increase of this business, the tanker market will shortly be found to be very bare of tonnage.

One of the first questions we had to consider on the conversion of an oil tanker to motor drive was whether the vessel should be arranged for Diesel electric-driven auxiliaries or adopt steam auxiliaries by retaining one of the main boilers and such of the present steam auxiliaries as were suitable for the new conditions. The arrangement with steam auxiliaries reduces the cost of conversion if the units already on board are in good condition and can be worked into the new scheme of things found on a Diesel motor-driven ship, but such an arrangement, while it shows very gratifying results in economy of operation and a certain

reduction in cost of conversion, can hardly be expected to give such favorable returns as we have a right to expect will be obtained in a more complete Diesel unit.

When the shipowner who handles cargo and passenger ships deals with the question of fitting Diesel motors, he is not immediately concerned with the consideration of retaining boiler power, beyond such small power as might be required for purposes of heating, which is only a minor matter.

In dealing with a general cargo boat, the same considerations have not had to be given to cargo handling as in the tanker, as we have no difficulty in obtaining electric-driven winches, windlass and steering gears of the highest type, which we have every reason to believe will be found much more economical in maintenance. With the electric auxiliaries, steam for power purposes can be entirely eliminated, and we thereby obtain the best conditions for a Diesel motor installation, as there is no question of doubt but what an all-Diesel installation is the ideal outfit.

Our experience has shown us that the ships now owned by the Shipping Board can, with very great advantage, be converted to Diesel motor-driven ships, and it will be found later that in the higher powered passenger boats the savings in fuel and space will be still more substantial. The adaptability of the general run of the Shipping Board ships to Diesel motor ships is admitted, and several shipbuilding firms are working on different types at the present time.

The Sun Shipbuilding & Dry Dock Company in the early part of the present year, in the adjustment of their business with the Shipping Board, purchased from the Shipping Board two oil tankers with Scotch boilers and geared turbines, 10,200 tons deadweight, and one general cargo boat, 11,800 tons deadweight with Scotch boilers and geared turbines, with the intention of converting these vessels from steam drive to Diesel motor drive, by removing the existing steam machinery and installing a Sun-Doxford 2-cycle opposed piston oil engine of 3,000 shaft horsepower each. The tankers have been dealt with first.

The main engines and the center and starboard main boilers of the two tankers were removed, and such steam auxiliaries as were unsuitable for the new power were also removed. The existing auxiliaries that were retained were relocated, and new foundations built and such other auxiliaries as were required were provided for, the main engine foundations were built and a new main motor of the 4-cylinder type, 3,000 shaft horsepower installed, with the new auxiliaries. The whole of the machinery was installed within the confines of the original bulkheads when the vessel was taken over. A new stern tube and shaft was fitted for the increased power put into the vessel over and above that previously developed with the turbines. The engines worked uncommonly well, without the slightest vibration. I may state that we were without data as to whether these hulls would set up vibration with this machinery being so far aft, but we were agreeably surprised to find that the working of the machinery developed a steadiness beyond that obtainable, even with our quadruple engines.

The *M. S. Bidwell* also had motors of the same size and type installed as on the *Miller County*, and after the necessary dock trials and river trial this vessel was sent on a trip to California. Neither of the motors in these two vessels had any shop trials on a test bed, yet they worked at the first trial and each succeeding trial without any failure whatever.

There is nothing mysterious in the construction of Diesel motors that need deter shipowners from adopting this type of power; the foremost marine motors on the market today are the product of good design and workmanship based on sound engineering principles. We are all familiar with the various developments from the low-pressure compound up to the present-day geared turbine, causing revolutionary changes, and at each step an improved economy was sought after; sometimes the gain was small, not exceeding 5 percent, and it

is not overstating the case when we assert that the gain from the compound engine up to the geared turbine of today has not exceeded 20 to 25 percent, taking all sizes of steam power on an average basis, yet the gain at each step was sufficiently encouraging to go forward. The shipowner was keenly alive to the value of the lowered fuel cost per horsepower and willing to invest his money in ships that would reduce his fuel bill and machinery weights.

If such economies were considered sufficiently advantageous to warrant investing in a new type of power, how very much more attractive from an earning standpoint should the Diesel motor be considered when we can offer the owner a saving in fuel alone of 55 to 65 percent. Further, when we consider the many advantages a lower fuel consumption means, it can be appreciated that it is not only lessened cost for fuel consumed that improves earnings, but less fuel consumed means less fuel accommodation in the shape of bunkers required, less fuel carried means an increased capacity for more cargo carried and a greatly increased steaming radius of the vessel.

The following known weights are set down for comparison only, but are fairly accurate:

ESTIMATED WEIGHTS OF PROPELLING MACHINERY FOR TANKERS

	Weight of Machinery, Long Tons	Fuel Oil Required for 25-Day Trip	Total
<i>S. S. Bidwell</i> , 10,200 D.W.T., 3 Scotch boilers, 2,700 S.H.P., turbines, gears and steam auxiliaries, including water in boilers	580	800 tons—boiler	1,380
Duplicate of <i>S. S. Bidwell</i> , 3 Scotch boilers, 3,000 I.H.P., triple expansion engine and steam auxiliaries, including water in boiler	670	875 tons—boiler	1,545
<i>S. S. Bidwell</i> , 1 Scotch boiler, 3,000 I.H.P., Sun-Doxford Diesel engine and steam aux., including water in boilers	758	375 tons—eng. and boiler	1,133
<i>S. S. Penna. Sun</i> , 13,000 D.W.T., 4 Scotch boilers, 4,500 I.H.P., quad. exp. and steam aux., including water in boilers	1,000	1,200 tons—boilers	2,200
Duplicate of <i>Penna. Sun</i> , 1 Scotch boiler, 4,500 I.H.P., Sun-Doxford Diesel eng. and steam aux., including water in boilers	1,007	725 tons—eng. and boiler	1,732
Duplicate of <i>Penna. Sun</i> , 1 small vertical boiler, 4,500 I.H.P., Sun-Doxford Diesel engine, Diesel and elec. aux.	980	530 tons—boiler	1,510

The weights here set down for tankers with steam auxiliaries and steam heating and cargo pumping outfit indicate the minimum of structural changes due to conversion to Diesel motor drive which are probably the least favorable conditions, yet they show remarkable savings over the steamer, but it will be noted when we consider the straight Diesel motor drive with electric auxiliaries throughout deck and engineroom that we get economies in weight and fuel required that amply repay the extra investment.

One further advantage the shipowners should bear in mind in considering the question of converting steamships to motor ships is the increased value of the shipping property, fitted with the Diesel motor. And we are forced to agree that as the number of motor vessels increase the value of the steamer will rapidly decrease.

The Sun Shipbuilding and Dry Dock Company is building the Sun-Doxford opposed piston two-cycle Diesel oil engine closely to the plans and data as furnished by Wm. Doxford and Sons, Ltd., Sunderland, England, out of their long extended experiments and research.

The motors built and installed by the Sun Shipbuilding and Dry Dock Company on the *M. S. Miller County* and *M. S. Bidwell* are the usual Sun-Doxford 2-cycle opposed piston type, 4 cylinders, 22¾-inch diameter, stroke of each piston 45½ inches, 3,060 shaft horsepower at 90 revolutions per minute. Weight of machinery, including fuel pump, flywheel, thrust shaft and Kingsbury thrust, 370 tons. The main motors for the *M. S. Challenger* are of the same size and type. This vessel, however, will be fitted with Diesel electric auxiliaries.

Economics of Transatlantic Liners of Various Lengths*

By Carl E. Petersen†

In view of the desirability of augmenting the present tonnage of the American merchant marine with vessels of the moderately large and fast passenger and cargo types, in order to make our marine a more balanced one, and because of the interest which is now manifested in these types, this paper has for its object an analysis of revenues and operating costs with a view to determining approximately how large a vessel could be built and profitably operated in the North Atlantic service under existing conditions. Needless to say, the analysis is based on observations and studies made during several years of close association with the variegated types of passenger vessels comprising the fleet of the United States Lines.

A PASSENGER or combination passenger and cargo vessel is primarily designed, constructed and placed in service for the transport of the maximum number of passengers, of the maximum amount of freight-earning cargo and mail, at a minimum expense, and hence, with maximum return to the owner on his outlay. It therefore follows that, granted proper operation, the financial success of a vessel in a particular trade involves or depends upon a predetermina-

Fig. 1

tion of the needs of the trade for the average life of the vessel and the suitability of the vessel, both as regards first cost and design, for that particular trade. The predetermination of the volume, class and time of passenger travel as well as cargo and mail transport is based upon general conditions and the owner's records.

METHOD OF ANALYSIS

The method adopted in the analysis was that of taking vessels from 500 feet to 1,000 feet of various lengths, determining dimensions and particulars which could be considered comparatively proportionate, and then preparing estimates of probable revenues and expenditures, using factors based generally on the performances of similar vessels in the same trade.

Length.—The length used is the perpendicular or under-water length, but in the case of the 1,000-footer the under-

water and overall lengths are approximately the same in order that that vessel may come within the limits of the Panama Canal locks.

Breadth.—The ratio of length to breadth has been found to increase with increased length in representative North Atlantic liners, the curve, Fig. 1, illustrating this. For this reason, a ratio length to breadth of 7.5 has been taken for the 500-foot vessel, increasing proportionately up to a ratio

Fig. 2

of 9.0 for the 900-foot vessel. A breadth of 105 feet has been used for the 1,000-footer, this being again a Panama Canal limiting size.

Draft.—A ratio breadth to draft of 2.5 has been used for all vessels.

Block Coefficient and Speed-Length Ratio.—A block coefficient of 0.68 in conjunction with a speed-length ratio of 0.75 has been used for all vessels, this being assumed to be an appropriate coefficient for the ratio. The speeds given by the speed-length ratio adopted are sufficiently high for all practical purposes with present costs of fuel.

Horsepower.—The shaft horsepowers have been calculated on the basis of maintaining at sea in any ordinary weather the speeds given. A propulsive coefficient of 0.60 has been used and a margin of power allowed.

Deadweight.—The total deadweight has been taken as a percentage of the load displacement, the figures used in each case are those shown on curve, Fig. 2, which is based on vessels actually built.

Passenger Capacities, Rates and Performances.—The passenger capacities for each vessel are those given by the curve, Fig. 3, which is based on representative vessels. The minimum rates used are those which in all probability would be estab-

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November, 1923.

†Naval architect, United States Lines, New York.

lished by the Atlantic Passenger Conference, the body controlling this feature. The average first-class summer rates have been found to exceed the minimum summer rates by 20 percent, and this figure has been used; all other passenger revenues have been based on minimum rates. The summer season for first-class rates begins eastbound with sailings April 1 to July 31 inclusive, and westbound with sailings

for each port of call. The port detention has been taken as 70 percent of time at sea. All figures are based on 334 days' service time and one month off (January) for annual overhaul.

Invested Capital.—The invested capital given in each case can only be considered as an approximate estimate of the cost to build in American shipyards and fully equip ready for sea, under present conditions, vessels suitable for the highest class and most exacting of passenger services. Curve 1, Fig. 5, illustrating invested capital plotted against length, is partly based on certain recent estimates made by representative American yards. However, the figures used may be considered sufficiently indicative of actual costs for a comparative analysis.

Freight and Mail Revenue.—Cargo revenue has been figured at a rate of \$10 per ton on the basis of 90 percent of capacity carried eastward and 40 percent westward. In the case of the 1,000-footer having a very limited cargo dead-

Fig. 3

July 1 to October 31 inclusive, the remainder of the year being designated winter season with reduced first-class rates.

The passenger performances expressed on the basis of percentage of capacity for each class plotted against length are illustrated in curves, Fig. 4, which have been prepared from the 1922 carrying results of a large number of representative vessels.

Crew.—Perhaps in no other phase of the operation of large liners does the personal equation play so large a factor as in the determination of what constitutes an adequate crew for a particular vessel. In this analysis the crew for each vessel has been determined separately, on a directly comparative basis by departments; the deck department complement varying with the size of the vessel, the engine department with the horsepower, and the stewards' department, cooks, etc., with the passenger capacities. The United States Shipping Board scale of wages has been used with allowances made for crew costs during the annual lay-up period.

Service and Port Detention.—For the purpose of these notes the vessels have been assumed to be on the New York, Plymouth, Cherbourg, Bremen run returning New York via Southampton and Cherbourg; in round figures a distance of 3,700 nautical miles each way. In estimating time at sea between terminals, an allowance of two hours has been made

Fig. 4.—Passenger Carrying Performances

weight, the 90 percent factor of the available capacity each way has been used.

Mail revenue has been determined on the basis of 3,000 sacks eastward for the 500 and 550-footers and 6,000 sacks eastward for the remaining vessels. No mail revenue allowance has been made for the westward trips for the reason that mail in this direction is usually carried on vessels flying the flag of the country from which the mail emanates. Eastward mails carried without special contract are customarily conveyed at a rate of 80 cents a pound for letters and postcards and 8 cents a pound for other articles. It has been

found that at these rates the revenue per sack will approximate \$5, this factor being used in the analysis.

Fuel.—Oil fuel consumed has been estimated at 1.1 pounds per horsepower hour with due allowance for port consump-

tion. Cost of fuel oil delivered at New York is \$10.80 per ton, at Bremen \$14 per ton, so the average cost of \$12.40 was taken in the fuel cost calculation.

Of course, with the smaller vessels having the available

deadweight, in view of the high cost of fuel relative to freight rates, it may be an advantage to carry round-trip fuel. In this comparison, however, all vessels are dealt with similarly carrying but one-way fuel plus an adequate reserve.

Subsistence.—Subsistence costs have been figured at the standard Shipping Board allowance of \$0.65 per man in crew per day and separate rates per passenger per day for each of the first, second and third classes.

Repairs and Supplies.—These have been taken at 5 percent per annum of the invested capital.

Towage, Pilotage, Wharfage, Dockage, and Port Dues.—Wharfage and dockage have been calculated for each vessel for the time in port. A cost factor, towage, pilotage and port dues expressed on a displacement tonnage basis was obtained from these costs of similar vessels in the same service and used.

Freight Handling and Mail and Baggage Expense.—This expense is, of course, proportionate to the quantity handled, factors from actual costs having been used.

Overhead.—Overhead—administrative, advertising, etc.—has been taken at 25 percent per annum of total operating costs.

Depreciation and Insurance.—Depreciation has been charged and insurance costs taken at 8 percent per annum of the capital invested.

Results.—Particulars of vessels, revenues, expenditures and results are given in Table I.

As a matter of interest in order that those unacquainted with the North Atlantic Service may realize the large variations, due in part to the season, in cargo and especially the passenger trades, there is given in Fig. 6, curves of total passengers and cargo performances both eastward and westward for a well-known vessel from January, 1922, until May, 1923.

CONCLUSION

For the greatest return on investment today, the 600-footer is the logical choice, a vessel of this length giving about 7 percent per annum return on investment. In this connection, it is interesting to recall and comment upon the wisdom of the Cunard Line in adopting this length for the majority of their post-war-built fleet of vessels.

If a return on investment of about 3 percent per annum would be considered sufficient, an owner would be justified in designing, building and operating a vessel of

750 feet in length; the construction and operation of any vessel having a length exceeding this cannot be justified from an American private owner's point of view under existing conditions. A European owner, however, with lower construction, equipment and operation costs, but with the same gross revenue, having in mind only a 3 percent return, could, of course, somewhat exceed this length; but for maximum return on investment the results would be analogous to the American comparison.

There are very few trips a year when the 900- or 1,000-footers will approach capacity in passenger-carrying performances, and during the remainder of the year these vessels will not carry any more passengers than, say, the 600- or 700-footers, the passenger traffic being so seasonal and the capital invested in lengthier vessels so increasingly large that these factors in themselves should indicate the economics of the very large vessels in comparison with more moderately sized ones. It may, therefore, be said that world conditions will have to very materially improve before the 1,000-footer is an economic probability for either a European or American company, although less so for the European.

Fig. 5, in addition to indicating the assumed invested capital, shows the results in Table I in graphical form. It is interesting to note that the items which render the very large vessel financially inefficient are insurance and depreciation, or those items dependent upon the capital invested, as well as the fact that the proportion of actual traffic to capacity is less in the larger vessel than in the vessel of more moderate dimensions. The present exceptionally high first costs are in part the deterrent to the building of large vessels.

North British 2,000 Horsepower Double-Acting Diesel Engine

By Our Special London Correspondent

A CERTAIN amount of preliminary information has already been published concerning the new type of double-acting two-cycle engine which the North British Diesel Engine Works has developed. The 2,000 brake horsepower two-cycle set which this firm is constructing for installation in a 5,000-ton cargo ship is now completed, and some details of the results achieved are of special importance in view of the fact that a great saving in weight and space has been effected by the adoption of this principle of operation.

As will be seen from the illustration, the engine has three cylinders, the dimensions being $24\frac{1}{2}$ inches bore and 44 inches stroke; the rated power given above is developed at 100 revolutions per minute. The length of this engine overall is only 30 feet, including the crankshaft driven scavenging pump and the air compressor. The height is approximately the same and the width over the bedplate is scarcely more than 10 feet. Perhaps the most important fact of all, however, is that the weight is only about 200 tons, whereas it is considered that an average four-cycle single-acting engine would weigh about 360 tons to develop equal power at the same speed.

On the left can be seen the control gear which is all hand-operated, the fuel pumps being driven by a mechanism on the sliding cylinder itself. The camshaft is thus eliminated with the idea of simplifying the design. Exactly the same principle of operation has been employed as in the experimental engine which was built before constructing this large set. The cylinder has a sliding motion and, in its movement in relation to the piston, uncovers the exhaust and scavenging ports at the correct times. The cylinder slides over the top and bottom covers, a distance of some 12 or 15 inches, and the gudgeon pin is brought out through slots in the cylinder, allowing the drive to be taken on to the crank-

New 2,000 Brake Horsepower, Double Acting, Two Cycle North British Diesel Engine

shaft through a forked connecting rod. The cylinders themselves are driven from the main crosshead pins and although the employment of sliding cylinders may seem to be somewhat surprising, it is claimed that no difficulties are likely to be encountered from this construction.

It is not to be expected that the fuel consumption of an engine of this class will be equal to that of a four-cycle single-acting motor. It was found on the preliminary trials that the figure attained was about 0.45 pound per brake horsepower hour, this being some 12 or 13 percent higher than with the modern Burmeister & Wain four-cycle single-acting type. It is possible, however, that improved results will be achieved with further experiments, and in any case the saving in weight and space—and presumably cost—is so important as to give the engine a wide field of application, should it prove thoroughly reliable in service.

Army Launches First All-Electric Dredges

TWO all-electric dredges, the *A. Mackenzie* and the *W. L. Marshall*, were launched on November 20 at the yards of the Sun Shipbuilding and Dry Dock Company, Chester, Pa. These dredges, which were built for harbor service by the Engineer Corps of the United States Army and equipped electrically by the Westinghouse Company, are the first all-electric vessels of this type ever built.

Two more dredges of the same type, the *Dan C. Kingman* and *Wm. T. Rossell*, will be launched at the Sun yards in the near future. On completion the *A. Mackenzie* will be assigned to Mobile Bay, the *W. L. Marshall* to the north Atlantic Coast, the *Dan C. Kingman* to the south Atlantic Coast, and the *Wm. T. Rossell* to Coos Bay.

Every detail of these dredges has been designed by the Engineer Corps. Electricity is used for every possible purpose, including propulsion, the operation of all auxiliary machinery, cooking, heating and lighting. Oil engines generate the necessary power; and the movements of the ships are controlled directly from the pilot house.

Factors Affecting the Economy of Lake Freighters*

Trade Conditions on the Great Lakes—Size and Speed of Vessels—Detention in Port—Influence of Nature of Cargo on Earnings—Operating Expenses.

By Professor Anders F. Lindblad†.

IT is well known that the transportation and handling of cargo in bulk is done on the Great Lakes at a very cheap rate. In fact, it is probably done more economically in this district than anywhere else in the world.

During the last few years there have not been any fundamental changes in the construction of the lake freighters. The vessels do not carry any machinery for handling of the cargo. The necessity for a quick dispatch has led to the installation on the docks of both loading and unloading machinery, which in turn is specially designed to suit each kind of cargo. It is largely due to the remarkable efficiency

the displacement has been possible only by increasing the length and by adopting a very full block coefficient; as a rule the block coefficient is 0.87 to 0.88. The depth of the vessels has been governed mainly by the height of the ore docks. In order to get sufficient slope on the ore spouts the vessel must not, when light, be too high out of the water. A molded depth of 32 feet to 33 feet has been adopted on the largest of the freighters.

GENERAL CONDITIONS OF THE LAKE TRADE

Bulk cargoes of iron ore, coal and grain form the main part of the trade on the Great Lakes. A large amount of stone, lumber, and general cargo is also carried, but such cargoes are usually transported by vessels of other types than the typical bulk freighters.

Nearly all the iron ore and the grain are shipped eastward from the ports on Lake Superior to the lower lakes, most of it to the Lake Erie ports. The movement of coal is in the opposite direction from the ports on Lake Erie to the head of the lakes.

Fig. 1 gives a summary of the trade from 1900 on. It shows that the amount of iron ore and grain transported is, in general, two to three times as much as that of the coal. This, obviously, means that the vessels on the westward journeys can secure cargoes for only about one-half to one-third of the number of trips. The remainder of these westward trips therefore have to be made without any cargo in the light or ballasted condition. Every shipowner, of course, wishes to get as many as possible of the available coal cargoes for his ships so as to avoid running them up the lakes without any paying cargo. There is therefore always a very keen competition in getting the contracts for moving the coal, which

Fig. 1.—Bulk Freight Movement on the Great Lakes

of this machinery that the bulk cargoes on the Great Lakes are handled with such an unusual speed and at such a low cost. The nature of this machinery has had such a great influence on the structural details of the ships that we may say that the design has been worked out mainly to suit the loading and unloading machinery.

The increase in size of the vessels has been most remarkable. In 1886 the largest ship was 303 feet long; in 1898 two vessels were built which were 455 feet long with 50 feet beam and a depth of 29 feet. The largest ships now on the lakes are *W. Grant Morden*, 625 feet overall length, 59 feet beam and 33 feet depth with a deadweight capacity of 14,200 gross tons; and the steamers *Col. J. M. Schoonmaker* and *Wm. P. Schneider, Jr.*, 617 feet overall, 64 feet beam and 33 feet depth, deadweight capacity 14,000. The majority of the newer ships have the following dimensions: Length on keel, 580 feet; breadth molded 60 feet, and 32 feet depth; deadweight capacity about 12,100 gross tons at draft of 20 feet.

While the length of the vessels has been gradually increased, the beam and the molded depth have not been increased in the same proportions. The beam has, to a certain extent, been limited by considerations of locks, narrow channels, etc., and by the reach of the unloading machinery. The draft is limited by the depth of water at the locks at Sault Sainte Marie and in the channels connecting the lakes. The available draft is at present about 20 feet. An increase in

*Paper read before the Society of Naval Architects and Marine Engineers, New York, November, 1923. The investigations in this paper were started in the summer of 1922, and the costs of the vessels are estimated as of that date. Since then there has been an increase of from 20 percent to 30 percent. This, however, does not have any material effect on the comparative results.

†Assistant professor of naval architecture, University of Michigan, Ann Arbor, Mich.

Fig. 2.—Freight Rates

naturally tends to lower the rate on this commodity. Owing to this condition the coal is generally transported at a rate of not more than about a half of the rate for iron ore.

The shipment of grain on the Great Lakes during the last few years has increased enormously, and is a very important factor in the operation of the lake freighters. Most of the grain is moved either late in the season, after the harvest, or otherwise early in the spring. While the rate on iron ore

Fig. 3.—Horsepower Curves

Length	Beam	Draft	Displacement Tons at 2,240 lbs.	Block-Coefficient
580'-0"	60'-0"	20'-0"	16,950	.8768
504'-0"	56'-0"	20'-0"	13,717	.8747
420'-0"	52'-0"	20'-0"	10,192	.840

and coal practically does not change during a sailing season, the grain rate fluctuates surprisingly from day to day. It is not uncommon that the amount of profit for the whole season largely depends on the rates which have been obtained for the last few trips with grain toward the closing of the navigation. There is always an uncertainty concerning the length of the sailing season, which is mainly governed by the weather conditions. The formation of ice, for example, may cause an early closing of navigation. This also has a great influence in making the grain rate changeable and subject to speculation.

Fig. 2 gives the rates obtained for the different kinds of cargoes. If we neglect the peak during the war years, it appears that the freight rates are slowly increasing.

As iron ore, coal and grain are some of the most important commodities of the American nation, it is to be expected that the rates for transporting them on the Great Lakes would, as a rule, follow the upward or downward trend, as the case may be, of the general economic conditions of the country. Lake transportation is so closely connected with the iron and steel industry that the condition of this industry is really the determining factor in the fixing of the freight rate on iron ore. It is also well known that the United States Steel Corporation, for example, through its control of the largest fleet of lake freighters, Pittsburgh Steamship Company, has a very decided influence in this respect.

ASSUMPTIONS

In order to make a systematic analysis of the various factors affecting the economy of the lake freighters it has been necessary to make a considerable number of assumptions, and these will be discussed in the following paragraphs.

To some extent I have followed the method used by Mr. Alfred J. C. Robertson in his interesting paper "Economical Cargo Ships."*

DIMENSIONS

For calculations three typical vessels were chosen with the following particulars:

Length	Beam	Depth	Displacement at 20' draft	Block coefficient
580'	60'	32'	16,950 long tons	0.876
504'	56'	30'	13,717 long tons	0.874
420'	52'	28'	10,192 long tons	0.840

The load draft was in all cases taken as 20 feet, which at present seems to be a fair average; although frequently some trips may be run at a deeper draft, when the water levels on the lakes so permit.

WEIGHTS

From a comparison of several of the present lake freighters the following hull weights (steel, wood and outfit) were obtained:

580 foot vessel,	4,287 long tons
504 foot vessel,	3,300 long tons
420 foot vessel,	2,426 long tons

The weight of the machinery was assumed to vary directly with the horsepower, and the weight in tons was taken as I. H. P.

4.7

SPEED AND POWER

Calculations were made for speeds of 10, 11, 12 and 13 statute miles per hour. The horsepower needed at the different speeds was estimated from some curves of results obtained from models of similar vessels, which have been tested in the University of Michigan tank. Fig. 3 shows the horsepower curves, and Table I gives the indicated horsepower as scaled off at the different speeds.

A propulsive coefficient of 0.60 was assumed, a value which experience seems to indicate is easily reached on these very full vessels. In fact, some of the published results do not agree with the tank results unless a higher propulsive coefficient is assumed.† The naval architects on the Great Lakes often figure with a propulsive coefficient of 0.65.

COST OF VESSELS

Table I gives the cost of the vessels as used in my calculations. The costs of the hulls, steel, wood and outfit were

power than for an engine of lower power. The price was taken to vary in direct proportion to the power from \$45.00 per indicated horsepower for machinery of 4,000 indicated horsepower to \$50.00 per indicated horsepower for machinery of 1,000 indicated horsepower.

The cost of hull and machinery was so chosen that with machinery for 12 miles speed the 580-foot would cost \$800,000.

TIME IN PORT AND NUMBER OF TRIPS

The actual time required for loading and unloading is very short, and some remarkable records have been made, as shown in Table II. It is not uncommon that even a cargo of 10,000 to 12,000 tons of iron ore is loaded into a vessel in about three to four hours. Often, however, there are delays due to congestion at the docks, when several vessels are waiting for their turn. But such delays are, in general, not very long in the coal and ore traffic. When the vessels carry grain there is quite often a more serious loss of time, particularly in the discharging end at the Lake Erie ports, where the grain elevators in the last few years have been unable to handle the increasing traffic in a satisfactory way. Delays of several days and even weeks have been rather common at the closing days of the season.

Table II shows that for vessels which carry only coal and ore the average stay in port is about thirty hours per round trip. Shorter delays, such as waiting for their turn to be taken through the locks at Sault Sainte Marie and encountering fogs and storms, will also cut down to some extent the time the vessels are under way. There is not much difference between the time a larger vessel has to spend in port and that of a smaller. For my calculations I have assumed that a speed-difference of one mile per hour will make a difference of two round trips during the entire season. Fig. 4 shows that this is approximately correct.

FUEL CONSUMPTION

The coal consumed was computed at 1.7 pounds per indicated horsepower per hour. It was assumed that the coal

consumption in port for every trip would be 16 tons for the 580-foot vessel, 12 tons for the 504-foot vessel, and 10 tons for the 420-foot vessel. Calculations were made for different prices of coal from \$4 to \$8 per ton.

OPERATING EXPENSES

All the operating expenses were figured on the basis of a season of 225 days. The wages for the crew were calculated from the wage scale of the Lake Carriers' Association, which was in effect during the season of 1922. The cost of meals was taken as 90 cents per man per day. The allowance for deck and engine stores was taken as \$6,000 for the 580-foot

Fig. 4.—Number of Round Trips During a Season (Assumed to Be 225 Days) at Different Percentages of Time Under Way

Fig. 5.—Time Under Way at Different Lengths of Stay in Port

ship, \$5,000 for the 504-foot and \$4,000 for the 420-foot ship. For each ship an amount of \$5,000 per season was added to cover management and overhead expenses.

The rate of insurance was taken as 4½ percent for the

total season, and the vessels were assumed to be insured to their full value as given in Table I. The charge for depreciation, repairs, and upkeep has been figured at 7.5 percent per annum of the first cost of the ships. The policy

Fig. 6.—Effect of Different Number of Trips with Iron Ore (No Coal or Grain Cargoes). Ore Rate 80 Cents per Ton

among shipowners on the lakes, however, is to be satisfied with a smaller percentage of depreciation.

In Fig. 13 the different items are shown as percentages of the total expenses, and Table III gives the corresponding figures in tabular form.

DISCUSSION OF THE RESULTS

The calculations show that the 420-foot ship has a very much lower earning capacity than a vessel of larger size

the calculations, say, for example, between a speed of 13 and 12 miles an hour. Figs. 4 and 5 indicate that, if the average detention in port is very long, it is not possible for vessels of higher speed to increase the number of trips sufficiently to meet the requirement that a speed difference of one mile an hour will make a difference of two trips during the season.

DETENTION IN PORT

Table II gives the average stay in port for vessels be-

with a length of 504 feet to 580 feet. All the smaller freighters on the Great Lakes are old, and they are built at a cost very much below the present prices. They have probably been written down to a small value in the books of the owners, and the depreciation and insurance charges can therefore be reduced to rather small amounts. For this reason they may still earn money when new vessels of the

longing to the Pittsburgh Steamship Company.* It shows that the delay in port has varied for these vessels from 25 hours and 27 minutes during the season of 1915 to 44 hours and 3 minutes during 1920—a difference of 18 hours and 36 minutes. From Fig. 5 it will be seen that this means that the vessels in the latter case had to spend in port from 7 to 9 percent more of the total time of the whole

same dimensions would not be able to make any reasonable profits.

There is not much difference in earning capacity between the 504-foot and the 580-foot ship. The 580-foot ship shows slightly better results when the price is low for bunker coal. Figs. 11 and 12 indicate that a vessel of about 540 feet length in most conditions will be very nearly as economical as the 580-foot vessel.

SPEED

From Fig. 6 it will be found that if a vessel with a speed of 11 miles an hour is not able to make two trips more during each season than a ship of 10 miles speed, then there will be a lower profit on the former vessel. The same is also true for a comparison between other speeds used in

season; in other words, the steaming time was reduced by this amount. Fig. 4 indicates that such a reduction would cut down the number of possible trips during one season to from two to four trips, depending on the speed of the ship and the distance between the ports. A change of about 8 hours in the average stay in port will, for a steamer of 11 miles speed, make a change of one trip in the total number of trips during a season.

It is evident from Fig. 6 that even a small decrease in the number of trips may seriously affect the financial result for the whole season. It is then clear that it is of uttermost importance for the lake freighters to keep the time in port down to a minimum.

*See page 183, Annual Report, Lake Carriers' Association, 1922.

Fig. 11.—Iron Ore Cargoes (No Coal or Grain Carried)

Speed in miles	10	11	12	13
Number of cargoes	18	20	22	24

KINDS OF CARGOES

Iron Ore: The lake freighters always derive the main part of their income from the iron ore shipments. Fig. 6 shows how the profit will change with the numbers of the ore cargoes, and Fig. 7 indicates how different rates on iron ore will affect the earning capacity. See also Figs. 11 and 12.

Coal: As previously mentioned, it is not common that these vessels carry coal cargoes up to the head of the lakes on more than about one-half to one-third of the number of the westward trips. Fig. 8 shows that these coal cargoes are, however, of great importance to the economy of the vessels, in spite of the fact that the coal rate is, in general, only about half that of the ore rate. No extra expenses are in-

Fig. 12

Kind of Cargo and Rate	Number of Cargoes			
	Speed in Miles			
	10	11	12	13
Iron ore at				
A 80 cents per ton.....	14	16	18	20
B 90 cents per ton.....				
Coal at 45 cents per ton.....	5	5	5	5
Grain at 3 cents per bushel.....	2	2	2	2
Price for bunker coal per ton.....	— . — . — \$4.00 — . — . — \$8.00			

curred directly for them, because the ships must in any case go up to the ports on Lake Superior even if they cannot secure any cargoes for this part of the trips.

The loading and unloading of coal cargoes takes longer time than the handling of iron ore cargoes. There is thus always a considerable delay in the ports when the former kind of cargoes is carried, and this should be kept in mind when considering the relative merits between taking coal cargoes or going up the lakes in the light condition.

Grain: In Fig. 9 some diagrams are drawn showing how the grain cargoes will influence the earnings. If at the assumed conditions, as stated in the diagram, two cargoes of grain are carried instead of two ore cargoes, it will be seen that, at a rate of 3 cents a bushel, the grain cargoes will increase the profits for the whole season approximately 1 percent. Should a rate of 5 cents per bushel be obtained, the profits would be increased by about 2.9 to 3.6 percent.

Fig. 13.—Cost of Operation

Speed in miles	10	11	12	13
Number of trips	16	18	20	22
Bunker coal at \$6.00				

As previously referred to, there is very often a serious delay at the grain elevators. If for this reason a ship would lose one more trip with iron ore, there would, with a rate of 3 cents a bushel for the grain, be no extra profits gained by taking the two cargoes of grain instead of three cargoes of iron ore. It is therefore rather common that the vessel owners in their grain contracts require a dispatch guaranty of \$1,000 to \$1,500 a day for each day a vessel is held in port beyond three days.

Fig. 9 clearly demonstrates that a high grain rate for only one or two trips may materially increase the profits for the entire season.

WAGES, MEALS, STORES, ETC.

In Fig. 10 is shown how a change in these factors may affect the results. It will be seen, for example, that an increase of wages of 10 percent will, for the conditions stated in the figure, reduce the profits from about 0.5 to 1 percent for the 580-foot vessel to about 0.7 of 1 percent

for the 420-foot vessel. An increase of 10 percent in the total expenses of wages, meals, stores, and management will cut down the profits for the 580-foot vessel about 0.7 of 1 percent as compared with about 1 percent for the 420-foot vessel. In other words, the larger ships will suffer less from an increase in the running cost than the smaller ships.

REDUCTION IN HORSEPOWER

In order to investigate to what extent a saving could be effected if forms of less resistance were designed, I have made some calculations based on horsepower 5 percent less than given by the curves in Fig. 3 on which my other calculations are based. They are plotted in Fig. 10. It will be seen that there is an actual gain in profits varying from 0.3 to 0.7 of 1 percent when the price for bunker coal is \$6. For a higher coal price the profits will, of course, be even further increased.

OTHER TYPES OF MACHINERY

With turbine machinery, a coal consumption of 1.2 pounds per indicated horsepower has been assumed. The coal price was taken as \$6 per ton. Against the saving of fuel has

Fig. 14.—540-Foot Vessel

to be set the 12 percent charge for depreciation, upkeep, and insurance on the addition of the first cost of the more expensive turbine. It was found that, in order not to increase the cost of operation, the first cost of the turbine machinery must not be more than \$35 per indicated horsepower above that of the reciprocating machinery. In other words, the turbine machinery had to cost less than \$80 to \$85 per indicated horsepower to be able to compete with the reciprocating engine.

For shipowners contemplating the building of new ships, the following points are, I believe, of special interest. They sum up, in a way, the results of the investigation.

1. Of vessels of ordinary proportions the 580-foot vessel is, in general, the best. One of 540-foot length is, however, very nearly as economical as the larger ship. A 540-foot vessel can with advantage be designed with a beam of about 63 feet. Fig. 14 indicates that such a vessel will be more economical than the present 580-foot vessels. For a 540-foot ship it seems to be best to adopt a block coefficient of about 0.875.

2. The available draft in the channels will undoubtedly in the future be increased. In order to take full advantage of an increase in the draft it will be necessary to construct the vessels with greater molded depth than at present. For a 540-foot vessel a molded depth of about 32 feet can probably be adopted.

3. With the present high coal prices it is not economical to increase the speed above 11½ to 12 statute miles (10 to 10.4 knots).

4. Owing to the higher first cost and the short season there seems, at present, to be no reason for experimenting with other types of drive such as turbines and Diesel engines.

Steam-Line Filters

(Continued from page 746)

there are 100 packs in a filter, and that only 1 percent at a time is necessary for clearing out the deposit or residuum, it is obvious that an increase of 1 percent of the filter is sufficient to effect continuous complete filtration. As a rule, with ordinary filters an increase of 100 percent, that is double the capacity of filter, is required to obtain these results.

It is quite immaterial, except for purposes of convenience, in what position the packs are placed, and filtration is effected quite as well horizontally as vertically. The illustration shows the end and side elevation of a filter of the horizontal type, the disposition of the packs in this case being easily understood. There are 24 packs each 6 inches in length, each containing about 1,400 sheets; the whole filter thus contains approximately 34,000 sheets. As each separate pack is capable of filtering 50 gallons an hour, the whole filter will deal with 1,200 gallons an hour, or nearly 5½ tons an hour. The reason of the large discharge from a filter of comparatively small size can be understood from an example. Assum-

ing the sheets to be so perforated as to contain 40 sources and sinks, that is 40 complete filtering units, there are obviously in the above example nearly one and a-half million units, or separate sources and sinks, continuously contributing their quota of filtration.

It is evident that the power required is not very great, since without considering losses, that is assuming efficiency of unity, filtration would be effected by a pump and motor of little more than ⅓ horsepower.

The natural inquiry of prospective users of the filter is as to the life of the paper employed for filtration. It must be remembered that the passage of the liquid between the sheets, i.e., through the films, is slow, and there is practically no wear from this cause. As far as any other deterioration goes, up to the present, experience shows that neither water, oil, paraffin, nor even weak acid solutions seem to have the slightest effect on the paper, which, as it is waterproof and oilproof, appears to be capable of being employed successively for a number of purposes, as long as it is washed through before use with each different substance.

Dr. Hele-Shaw said further that the operation of the filter showed that no trace of solid matter penetrated between the sheets and that grit never passed between them. There was only a stream-line film of liquid between the surfaces and, consequently, it could not be conceived that these surfaces would wear out.

Various mixtures and solutions have been experimented with. With a mixture of dirty oil and water (bilge water) the oil took up the dirt and the dirt and oil separated from the water, but, if the oil were clean, the oil and water both came through the filter together and afterwards immediately separated.

Failure of Condenser Tubes*

By William R. Webster†

Both tube makers and tube users have given much consideration to the problem of providing and securing tubes which would give maximum length of service, but due to the erratic nature of corrosive attack and the large element of time involved, it cannot be said that sufficient facts have been established on a basis of scientific procedure to make it at this time possible for anyone within certain very broad limits to predict with certainty that any particular lot of tubes will endure under average service conditions in a measurably superior degree to some other tubes differing from them in material respects. Since the matter is one of very great importance in the conduct of power installations, careful study of the problem in all of its aspects is well warranted in the interest of good engineering practice.

FEW problems relating to the operation of steam power plants, both marine and stationary, involve greater perplexities than those surrounding the endurance of the tubes employed in surface condensers where salt or contaminated cooling water is used. Failures experienced are of two kinds. One is due to spontaneous longitudinal splitting of the tube which is an exhibition of the phenomenon known as season cracking. The other is caused by the corrosive attack of the cooling water or of substances carried by it. In point of frequency of occurrence, the former is now of relatively minor importance, but because of the fact that when it is encountered it involves sudden and extensive leakage, its immediate results may be of greater consequence than failure due to corrosion because the latter is gradual in approach and manifestation.

COMPOSITION OF TUBES

Originally most condenser tubes were made of a mixture of about 70 percent of copper and 30 percent of zinc, this composition being dictated by considerations affecting the manufacture rather than the performance of the tubes. Experience having demonstrated that the presence of a small amount of tin retarded the corrosive effects of sea water, some experiments were made in which one percent of tin was substituted for 1 percent of zinc, with the result that superior resistance to corrosion was obtained. This specification was originally adopted by the British Admiralty since which time the term "Admiralty mixture" or metal has been employed to designate it.

It was stated above that season cracking was a recognizable cause of tube failure. For this a complete and sufficient remedy is a moderate degree of annealing. It was originally the practice to furnish condenser tubes hard, i.e., without any final heat treatment. No way is known to the art by which tubes so made can be positively assured against this trouble. On the writer's recommendation, the Bureau of Steam Engineering of the Navy Department somewhat over 20 years ago adopted specifications requiring that tubes be annealed after the final drawing operation. This practice has since become standard in this country although English manufacturers still continue to omit a final annealing.

The Admiralty mixture is hot short and can consequently not be made into tubes by the customary method of hot piercing a solid billet or blank. Instead the usual practice is to make the initial casting in the shape of a hollow cylinder. To form this, appropriate amounts of copper, zinc and tin, together with a suitable quantity of scrap, are brought to a molten state and then poured into a vertically disposed cylindrical mold of cast iron in the center of which a cylindrical sand core is supported.

Only the highest grades of material obtainable are employed. While the impurities carried by slightly lower

grades have never been proved to have an effect on service endurance they do affect the ductility of the material and cause a resulting increase in its cost of manufacture entirely out of proportion to any saving in initial cost.

Lead and iron are considered deleterious impurities. In excess both hamper the operations of the tube maker, and the latter in particular is believed to assist the attack of corrosive agencies. The effect of such other impurities as normally exist in well made brass has not been shown to be of material consequence.

Objection is sometimes made to the use of scrap, but if it is understood that the term scrap is not synonymous with junk and that an inferior mixture results if too large a proportion of elemental metals be employed, no grounds for such objection exist.

PROCESS OF MANUFACTURE

The resulting casting, or shell, about 4 inches in outside diameter by $\frac{5}{8}$ inch thick by 50 inches long, is by a succession of cold drawing operations reduced to a tube having

Longitudinal and Cross Section of an Acceptable Shell Casting

a cross sectional area of about 0.15 square inch involving an extension of each element of the original casting of 40 to 50 times. The severity of the first drawing operation is such that metal of an inferior quality, either due to unskillful casting or deleterious impurities, is unable to withstand it and breakage inevitably results. As the drawing operations continue, the tube becomes too long for convenient handling so that it is cut into appropriate lengths from time to time. Departure from the cast state increases the normal ductility of the metal somewhat so that later reductions are correspondingly greater than the initial ones.

IMPORTANCE OF ANNEALING

The annealing operation to which the tube is subjected is an important one since the ductility of the metal is within limits a function of the temperature to which it is heated

*From a paper on "Condenser Tubes" presented before the Metropolitan Section of the American Society of Mechanical Engineers in New York on November 8.

† Vice-president, Bridgeport Brass Company, Bridgeport, Conn.

in the process. Since annealing is employed for the purpose of removing the hardening and embrittlement due to drawing, it is manifest that it should be so governed as to produce maximum ductility. Careful pyrometric control is therefore essential to good practice in this respect.

It was heretofore stated that one of the causes of tube failure was due to a phenomenon known as season cracking which could be prevented by annealing after the final drawing operation. By properly governing the drawing operations the tendency to season crack can be controlled to some degree, but it cannot by this means alone be eliminated with certainty.

Since a condenser tube when fully annealed is so soft as to be readily distorted by treatment incident to handling and installation, it is customary practice to modify the final

experience does not indicate that it is of much consequence on the whole in preventing corrosive attack. The belief is very widely held that the control of annealing temperatures within close limits and extreme freedom from mechanical defects are essential to satisfactory endurance. In the former case, fortunately, ample evidence is available and merely lacks sufficient examination. The tubes in a condenser usually fail in succession, some giving a much longer life than others. Such failures must be due to causes either internal or external to the tubes. The latter in individual condensers do not usually vary greatly from tube to tube and when differences in this respect do occur, they can usually be detected. Under these circumstances, when variations in detectable internal conditions exist a sufficiently large number of observations should be able to determine with certainty any relation existing between any specific internal condition and superior or inferior service endurance.

For example, if a small crystal structure is more conducive to long life than one relatively large, the earlier failures in an individual condenser will be found upon examination to possess, on the average, larger crystals than those which fail subsequently, with some degree of proportionality observable between the crystal size and the life of the tube. Comparative examinations of large quantities of failed and unfailed tubes from the same condensers, while always showing variations in crystal size of considerable amounts, have not given the slightest support to this belief.

Similarly, attempts to explain observed failures by the presence of mechanical imperfections have been unfruitful. Dr. G. D. Bengough, in discussing this factor, has stated that "in my (his) experience it is very rare for tubes to fail from this cause." Should, however, the facts above mentioned be admitted by all, that alone would contribute but little to the solution of the problem of condenser tube failure. On the other hand, if such admission should serve to direct attention to the importance and necessity of more intensive study of the causes of corrosion which reside within the condenser, much would have been accomplished in the direction of substantial progress.

A discussion of the precise mechanism of the corrosive attack involved in the failure of condenser tubes is beyond the scope of this paper. Suffice it to say, therefore, that the corrosive agencies existing in the average surface condenser using sea water are sufficiently active to make the destruction of any brass tube only a question of time, and that the reason why brass tubes last on the whole as well as they do is that corrosive action is usually accompanied by the formation of by-products which are distinctly protective. Specifically, if a piece of condenser tube be immersed in warm salt water containing air bubbles, corrosive attack will continue for a considerable period at a rate sufficient to completely dissolve it in a very few months. Also corrosive attack of a character not involving the formation of a protective coating may occur under perfectly normal conditions and proceed at a rate sufficiently rapid to perforate the tube in a few weeks.

PLUG TYPE DEZINCIFICATION

Investigations of the subject of condenser tube corrosion have established the existence of a considerable number of distinctive types of attack. Probably the most troublesome is that usually known as "plug type dezincification," wherein approximately circular areas of the tube wall of small size are so attacked that the zinc appears to have been dissolved out, leaving a spongy mass or plug of copper behind.

This action once set up continues at a rapid rate until the wall of the tube is perforated. The spongy copper is not strongly adherent, and frequently falls or is washed out of place, leaving an approximately circular hole.

This type of corrosion is the one which usually accounts for the rapid failure of new tubes. Perforations from this

Curve Showing Relation Between Annealing Temperature, Physical Properties and Crystalline Structure of a Condenser Tube

anneal to a degree that will, while removing all liability to season cracking, still leave the tube hard enough to withstand handling.

The metallurgical microscope is an extremely useful instrument for determining whether the annealing operation has been so conducted as to prevent season cracking on the one hand and undue pliability on the other, but its value as a means of predicting service endurance has not been established by any well attested record of experience.

FAILURE DUE TO SEASON CRACKING

It will be at once evident that failure due to season cracking is readily and completely avoidable, since the degree of annealing necessary to prevent it is well below the point at which the metal becomes unduly soft. In order to guard against this latter possibility it has sometimes been thought necessary to require that a unit length of the tube be capable of sustaining a specific load applied perpendicularly to its axis without taking a permanent set exceeding a certain amount. As the size of the crystals of the tube can be determined microscopically with a fair degree of approximation and since this size is proportionate to the softness of the tube, this requirement is unnecessary in the presence of a definite limit for the crystal or grain size. In this connection, however, it is desired to call attention to the fact that the factor of observational error involved in the measurement of crystal size is a large one.

FACTORS AFFECTING ENDURANCE

While perfection of manufacturing practice may well be stressed as of importance in the way of good workmanship,

PREVENTATIVE MEASURES

In general tubes should be cleaned as frequently as possible, particularly when first installed. Deposits of foreign matter, especially when foul water is used, are frequently of a highly corrosive nature. In the writer's experience iron protective plates properly attached to the tube sheets have a distinct value and should always be employed. The omission of the final pickling operation so as not to disturb the oxide scale formed in the final anneal has been recommended by a distinguished authority. Experimental observations indicate that it is well worthy of extended trial.

This discussion heretofore has concerned itself only with tubes of Admiralty mixture as their use is indicated in most cases where corrosive action is to be expected. In installations employing uncontaminated fresh water Muntz metal gives satisfactory results. This mixture, which is approxi-

**Inside Surface of Tube, Showing Plug Type Dezincification.
The Tube Has Been Split Longitudinally**

cause may take place within a few months or even weeks from the time the tubes are installed. The chemical reactions involved are complex but appear to be favored by a high degree of salinity. Frequently the attack occurs along the bottom element of the tube under conditions indicating that, when drained, water has collected in the bottom and that concentration due to evaporation has occurred. Attempts to produce this action experimentally have not been entirely conclusive. A slight inclination of the condenser so that the tubes will drain dry and the avoidance of sagging appear to have value as preventive measures, and should always be adopted. Frequent thorough cleaning of the tubes when new is also desirable, particularly if the condenser is out of service for extended periods.

Under certain circumstances a type of corrosion resembling this is encountered which differs from it in that the action instead of being localized occurs quite regularly throughout the entire wall of the tube and proceeds at a much slower rate until the whole tube becomes brittle and lacking in strength. This is observed usually only in installations that have been in operation for many years although Muntz metal tubes generally fail in sea water from this cause in a relatively short time.

Quite frequently failures occur from an action as a result of which the wall of the tube is dissolved in an irregular manner, sometimes involving extensive areas and sometimes quite restricted ones. Continuous action of this character usually reduces the thickness of the tube particularly at and near the inlet end so that the packing no longer functions although it frequently localizes in a way that produces perforation without much thinning of the adjacent portions. Dr. Bengough has investigated this type of failure and proved conclusively that it is due to the presence of entrained air in the condensing water. This may be due to

Sections of Condenser Tube, One Part of Which Has Been Perforated Due to Entrained Air Corrosion; the Other Portion of Which, While Entirely Free from Attack, Shows a Large Spill

mately 60 percent copper and 40 percent zinc, is inherently cheaper than Admiralty and the process of manufacture less costly, due to the fact that it is capable of being worked hot.

The writer has for years vigorously opposed the contentions of those who hold the belief that crystalline structure or mechanical imperfections are causative accompaniments of corrosive attack, and in support of his position has presented evidence and cited authority. The attitude is and was not dictated by any lack of appreciation of the importance of these factors from the standpoint of good workmanship and practice, but results solely from the conviction that as long as their suspected presence is assumed to account for premature failures the sufficient remedy for which lies in increased severity of inspection, no progress in determining and controlling the factors depending on condenser design and operation is to be expected.

SPECIFICATIONS

Engineers in the endeavor to avoid the very serious difficulties incident to the premature failure of tubes in service have exhibited considerable ingenuity and industry in drawing exacting and conflicting specifications. It can, however,

various causes such as improper design of circulating pumps, leaks in the suction line or disturbances in the vicinity of the intake. He recommends soaking the tubes in quiescent sea water at 40 degrees C. for about a week. This appears to form a protective coating.

Applications of Arc Welding to Ship Construction—V

Tables Showing Time Required for Various Type Electric Welded Joints as Compared with Riveted Construction

By E. H. Ewertz*

IN comparison with riveted construction, the use of electric arc welding in ship work shows a reduction in weight and a saving in the time element—with consequent savings in cost. Instances have previously been mentioned in this series of articles where weight in hull construction has been reduced over 25 percent while the hours of labor have been cut 20 percent. Examples are also mentioned in cross channel barge assembly where 245 man-hours were saved in the construction and more than 1,000 pounds of metal saved by utilizing welding instead of riveting. The tabulations in this installment deal mainly with the time factor in connection with ship welding.

COST SAVINGS OF WELDING

The cost saving element of welding in ship work has already been discussed in the analysis of the work on cost data as carried out under the supervision of Mr. W. S. Wakeman, general manager of the Fore River Plant of the Bethlehem Shipbuilding Corporation. The results of the investigations were published in Tables 1 to 10 on pages 628-629 of the

October issue of MARINE ENGINEERING AND SHIPPING AGE.

Reference was also made on page 628 to Tables 12 to 24 which appear below as showing in tabulated form the time required to weld seams and holes. As can readily be understood, precautions were taken in making the tests to be certain that operators were competent and that the best of material and equipment were used. The work was done by both the

(To be continued)

Protective Coverings for Shipbuilding Purposes: Paints

By Horace Holden Thayer*

Continuation from the October issue of a series of articles containing information regarding shipbuilding materials and their uses that is not readily obtainable from shipbuilding handbooks and other generally available sources. The articles are not intended to be a complete exposition of the subject but will be found to contain items of value to the various classes of workers in this field who have to deal with these materials from the materials point of view.

SHELLAC as previously stated is gum shellac dissolved in alcohol. Navy Department specifications for clear shellac call for 6 pints 1 gill of grain alcohol and 2 pounds 6 ounces of orange gum shellac per gallon. Colors are obtained by the addition of dry pigments. For furniture the shellac is grade A, and for other work, grade B. Their specifications for the orange gum shellac embody the following requirements:

GRADE A QUALITY

1. For pattern and varnish work.—To be of a grade similar in quality to the brand known commercially as "Double Triangle G," and must be friable by hand without the use of any tools. When treated with hot 95 percent alcohol, the residue of insoluble matter must not exceed 1¾ percent, and the shellac must be free from resin and other adulterants. All deliveries must be equal in color and in all other essential respects to the standard sample of this grade of shellac.

GRADE B QUALITY

2. For coating linoleum-covered decks.—To be of good quality and must be friable by hand without the use of any tools. When treated with 95 percent hot alcohol, the residue of insoluble matter must not exceed 3 percent. It must be of one of the following two qualities: (1) Free from rosin and have an iodine number of less than 18 as determined by method of subcommittee on shellac analysis (Journal of the American Chemical Society, pages 1221 and 1227, Volume XXIX, No. 8, August, 1907); or (2), the grade known commercially as "U. S. S. A. Standard TN," containing not more than 3 percent rosin. The grade of shellac known as "New York Standard 3 percent" will not be accepted. Deliveries of resin-free shellac and "U. S. S. A. Standard TN" must in all essential respects be equal to their respective standard samples of these grades.

GRADE C QUALITY—GARNETLAC

3. Garnetlac for coating linoleum-covered decks.—To be of good quality and ground fine enough to be readily soluble in alcohol. When treated with 95 percent hot alcohol, the residue of insoluble matter must not exceed 1 percent. To be free from resin and have an iodine number of less than 18, as determined by method of subcommittee on shellac analysis, referred to above. All deliveries must be equal in all essential respects to the standard sample of this grade of shellac.

BRIGHT FINISH WORK

A good standard of requirements for bright finish work in first class accommodations and similar spaces is as follows. The shellac is required to keep the stain or filler from coming through the varnish.

POPLAR

- 1 coat linseed oil 25 percent, turpentine 75 percent
- 1 coat oil stain containing 50 percent turpentine
- 1 coat shellac
- 2 coats interior varnish

OTHER WOODS

- 1 coat paste filler slightly darker than the natural wood
- 1 coat shellac
- 2 or 3 coats interior varnish

HARDWOOD FLOORS

- 1 coat paste filler
- 1 coat shellac
- 2 coats prepared floor wax

SPREADING POWER

A knowledge of the spreading power of paint, varnish, etc., is of considerable value in determining the kind to use as well as in determining the amount necessary. Some high priced products are found to be cheaper than those of lower price when the comparative spreading power is taken into account.

Dr. A. H. Sabin, whose work has been referred to in the section of this article dealing with priming paints, figures that a pure red lead paint, mixed in the proportion of 28 pounds of dry red-lead to 1 gallon of pure linseed oil, without turpentine or other thinner, when applied to average new structural steel surfaces will cover from 500 to 700 square feet per gallon for the first coat, from 650 to 800 square feet for the second coat, and from 700 to 850 square feet for the third coat. Thus for a combined priming and second coat, 1 gallon of paint will cover from 300 to 400 square feet, and for three coats 1 gallon will be required for every 215 to 245 square feet. Paint made up with paste red lead is considered to have a greater spreading power than similar paint made from dry red lead.

When figuring for estimating purposes more conservative amounts are usually used. These for one coat will be around 200 square feet per gallon for bottom compositions and 300 square feet per gallon for all other paints, including the priming paint.

Approximate figures given by the Navy Department for the spreading rates of their paints are of value and those of greatest interest in connection with this article are here given:

	Square Feet
Hand mixed red lead.....	450
Anticorrosive-Norfolk No. 17.....	270
Antifouling-Norfolk No. 19.....	243
Boottopping, red	405
Boottopping, light gray.....	684
Outside white	486
Outside black	477
Spar color	495
Inside white	432
Flat white	540
White enamel	540
Spar color for smokestacks	333
Light gray for smokestacks.....	477
White canvas preservative	70
Under cork	135
Clear shellac	450
Red or yellow shellac	369

PAINT SPRAYING

Of recent years the practice of applying such paints as priming paints and bottom compositions, and applying paints elsewhere where large surfaces are involved, with machines operated by compressed air, called paint guns, has become more and more prevalent. They are great labor and time savers as one machine will frequently do the work of five or more men.

Although the spraying machine manufacturers insist that it is not necessary to dilute the paints in order to apply them in this manner, this dilution is frequently practiced to the

*Member of the firm of Rossell & Thayer, naval architects and marine engineers, Philadelphia, Pa.

extent of materially impairing the protecting value of the paint.

PAINT COLORS

Some colors are not lasting under shipboard conditions and others are undesirable in certain locations on account of soiling readily, the general effect produced, or for other reasons. Color schedules that have been tried out and found to give good satisfaction are therefore of value, and such a schedule is here presented. The bottom compositions and boottopping would be of the standard colors for the compositions used.

BLACK

Outside of hull from L. W. L. to rail, when the boottopping is dark.

Fire room ventilators, coaming and cowls.
Deck machinery and foundations.
Steering engine.
Bits, clocks, etc.
Anchors and hawse-pipes.
Stack.
Uptakes, etc.
Rigging fittings in way of black paint.
Deck fittings.

GRAY

Outside of hull from L. W. L. to rail, when the boottopping is gray.

Underside of decks in holds and 'tween decks.
Inside of poop, bridge and forecastle cargo and stores spaces.
Hold ventilators.

GREEN, LIGHT

Underside of deck over promenades.
Underside of deck over steering stations.
Underside of screens over windows.

LEAD COLOR

Canvas decks.
Hatch covers.
Cargo battens.

RED, BRIGHT

Inside of ventilator cowls.

RED, DARK

Topside of steel decks where painted.
Waterways.
Machinery foundations in engine rooms, etc.

RED, OXIDE

Sides of cargo holds and 'tween decks.
Inside of steel hatch coamings.
Outside of shaft tunnel.

SLATE COLOR

Boiler room.
Engine room dado to 3 feet above the working platform.
Shaft tunnel dado to 3 feet above the working platform.

SPAR COLOR

Outside of superstructure below grab rail.
Outside of hatch coamings.
Low skylights.
Masts.
Outside of hold and engine room ventilator coamings and cowls.
Propelling machinery and auxiliaries.
Ice machines.

WHITE

Outside of poop, bridge and forecastle above rail.
Outside of superstructure generally above grab rail.
Exposed woodwork generally except decks, machinery foundations and hatch covers.
Partitions in quarters, etc.
High skylights.
Companions.
Ice machine room.
Dynamo room.
Engine room above 3 feet high dado.
Inside of engine and boiler casings.
Engine room ventilators.
Inside of shaft tunnel above 3 feet high dado.
Ridge poles and spreaders.
Rails and stanchions.
Flag poles.
Boats and davits.
Life rafts.
Rigging fittings in way of white paint.
Small canvas covers for binnacles, rope reels, ventilator caps, etc., waterproofed.
Binnacles, if not natural or bright finish.
Ship's name.

The Navy Department has formulated a color scheme for piping which is of great value in enabling the ready determination of the service of the piping, and this system has been largely adopted in merchant practice. Their specifications for this are:

Standard Coloring for Piping.—All voice pipes shall be painted the shade and color of the surrounding surfaces. The body color of all pipes or pipe covering, exclusive of pneumatic piping, which shall be painted in its distinctive color throughout, shall conform in shade and color to that of the surrounding surfaces, except on edges and side of flanges, where the distinctive colors shown in the following sketch shall be painted. The edges of flanges of fuel oil filling pipes, down to the tank; when no manifold is fitted, shall be painted the same color as delivery pipes, *i. e.*, red. Where a pipe has no flanges, the couplings and elbows shall be painted as per standard at flanges. Where a pipe has neither flanges nor couplings, a circumferential band, or bands, containing the distinctive colors, shall be painted at suitable intervals. No compartment shall be left with pipes unmarked.

The sketch referred to shows the color around the flanges and the color of bands painted on the pipes about one inch away from the flanges. The following schedule gives the same data. The bands are 4 inches wide unless otherwise stated:

		Flanges	Bands
Steam piping	Supply	Black	White
	Exhaust	Red	White
Salt water piping	Suction	Black	Green
	Delivery	Red	Green
Fresh water piping	Suction	Black	Lead color
	Delivery	Red	Lead color
Hydraulic piping	Supply	Black	Blue
	Exhaust	Red	Blue
Ventilation piping	Supply	Black	Yellow
	Exhaust	Red	Yellow
Fuel oil piping	Suction	Black	Red (2"), white (2"), red (2")
	Delivery	Red	Red (2"), white (2"), red (2")
	Both services	1 Black, 1 red	Red (2"), white (2"), red (2")
Drains, scuppers, air pipes, sounding pipes		White	White
Fire main		Red	Red
Flooding pipes for magazines, peak tanks, etc.		White	White with red lengthwise stripe
Pneumatic piping		Black	Black (continuous)
Air-water ejecting system		Black	Red (2" next flange)
			Black (next 6")
Carbon dioxide fire extinguishing system		Black	White (2" next flange)
			Black (next 6")
Refrigerated water piping		Red	Lead color with 2 white squares
Hot water piping		Red	Lead color with white lengthwise stripe

CONSUMABLE STORES

Paints carried for the painting of topsides by the crew, and other work about the vessel, should be in conformity with those previously applied. A good selection of engineers' consumable stores for the general run of merchant ships is as follows:

	Quantity
Asphaltum, black	5 gallons
Brown, metallic, ground in oil	25 pounds

	Quantity
Graphite (amorphous) in 5-pound cans.....	10 pounds
Japan drier	2 gallons
Lamp black	2 pounds
Linseed oil, boiled and raw	20 gallons
Litharge, for ammonia joints or as drier.....	5 pounds
Prussian blue, for bearings and gears.....	1 pound
Red lead, dry, in 25-pound kegs.....	100 pounds
White lead, in oil, in 25-pound kegs.....	50 pounds
Turpentine	10 gallons

Insurance Companies Seek Settlement for War Losses

Claims Allowed by Washington Commission Against Germany Will Be Awarded to War Risk Insurance Companies Who Paid Losses on American Ships

By "Bordereaux"

THE most interesting, though not the most unexpected, occurrence in marine insurance during the past few weeks has been the denial by the Mixed Claims Commission, sitting at Washington, of the demand of Americans for the recovery from Germany of amounts paid by them for war risk insurance during and immediately after the World War. This outcome of an unjustifiable desire to get something for nothing out of the Teutons has repeatedly been predicted in this department of MARINE ENGINEERING AND SHIPPING AGE. The underwriters were not out anything, because they had accepted the hazard and been content with the extra remuneration received by them; nor were the ship-owners in position to pose as claimants, because they had long since passed the extra cost along to their consumers. Nevertheless, there was a great rush to try and get something out of Germany, the total running into hundreds of millions.

The Commission has still to rule upon the various claims for damage to or destruction of property of American nationals by Germany and her allies; and under this classification will come the claims for ships and goods lost by the sinking of ships by submarines, mines and otherwise. When claims are allowed for the loss of property by Americans, and the owners of such property have already been indemnified for their losses by war risk insurance companies, the latter will figure as assignees of such claims under the subrogation they took when they paid the claims, and it is the expectation of the underwriters that in such cases the claims will be paid to them under such subrogation agreements.

In passing adversely upon the claims for refund of war risk premiums, the Commission stated its conclusions as follows: "It is evident that during the period of neutrality both groups of belligerents freely resorted to 'retaliatory measures,' to the detriment of all neutral commerce, over the vigorous and repeated protests of the Government of the United States; and in both theory and practice, as demonstrated by actual experience, the American nationals insured against the risks created by the acts of both groups, risks inevitably incident to the very existence of a state of war. Obviously it is impossible, therefore, to attribute these risks to the acts of Germany without holding her liable for all the consequences of the war, which, under the treaty, is not permissible. In this group of claims there is no complaint of injury to or destruction or seizure of property by the act of Germany or her agents. The sole complaint is that the hazards of war required the claimants as a matter of business prudence to protect by insurance against risks which never matured into damage to or destruction of the property insured, and the claimants seek to recover from Germany the cost to them of such insurance."

Hull Insurance Unsatisfactory

STUDENTS of marine insurance in Great Britain have been making approximate surveys of the progress of hull underwriting in 1923 and they are unanimous in declaring that rates are too low, conditions too liberal, and that there is urgent need of a closer agreement among underwriters for their own protection. Throughout the year the decline in both hull and cargo rates has been steady, even to the point of absurdity; and that in the face of a more than normally heavy loss experience. There is the slimmest chance of underwriting profit this year.

A dependable authority states that losses of British steamers which in tonnage were greater in 1922 than in 1921, are above the 1921 total, and are likely to exceed the 1922 total with average losses to the end of the year. American steamer losses, which in 1922 were below those of 1921, reached the 1921 total before the end of October. Taking underwriting figures on steamers for time on Institute clauses, *Fairplay* insists that it will be found that the 1922 account is running off with a considerably greater loss than the 1921 account at the same period, and that there is every probability of 1923 going badly also. The fact that, owing to the low freight rates obtainable, only the better class of boats has been employed is, naturally, in favor of the underwriters. Experience during the present year has led underwriters to discount the familiar contention that the marine hazard has been reduced because of the various improvements in navigation.

Repair costs are not coming down. An American underwriter informed a friend recently that on one of his risks the repair of a crankshaft involved a cost equal to one-half the insured value of the steamer. In Great Britain the hull business is the important end of the market to the underwriter. In the United States it is the reverse, as Americans have never been keen over hull lines.

London has gone after American hull business in the most deadly earnest, quoting rates that made competition on this side impossible. Secure in the holding of their English business they have been offered quotations for American vessels at substantially lower figures than they accorded their own nationals. Then, when they had corralled everything in sight over here, they got together, last September, and decided to abandon cut-rate methods and stand out for the maintenance of rates and conditions at a fair figure. In this apparently desirable action they invited the defeated American underwriters to join in locking the barn after the horse had been stolen. If London is now discovering that an underwriting loss lies ahead of them it does not come to

the American underwriters as a surprise. The famed British "world spread" will have to help London out of its hole.

On-Deck Stowage

FALL and early winter storms on the Atlantic have been bringing their usual quota of losses and considerably more this year. Under such circumstances it has been only natural that cargo stowed on deck should have suffered in proportion, and underwriters have been watching this class of business with keen eyes. It is one of the fundamental principles of marine insurance that cargo shall be stowed in accordance with the recognized rules of shipping and in most cases this means below deck. The responsibility for violation of this rule may involve the shipowner and operator and it is essential that these interests be acquainted with the rules and regulations of the trade. In issuing the usual form of basic cargo policy, where no mention is made of the place of stowage of the cargo, the underwriter is protected against the possibility of loading on deck cargo which is customarily loaded under deck.

If a vessel owner gives a clean receipt for ordinary cargo the cargo must be stowed under deck and if it is loaded on deck the vessel owner does so at his own risk. In such an instance the basic form of marine policy would not attach on goods, as the merchandise was not stowed in the customary place for the carriage of such cargo. Should damage to the cargo eventuate, the owners would be compelled to look to the vessel owner for reimbursement. Acids and other highly dangerous commodities are, in many instances, required by law to be carried on deck. Therefore, even though the assured neglects to state that such goods are actually laden on deck, the underwriter would be liable, if so laden, without notice.

Lumber is frequently insured on deck, subject to regular f.p.a. conditions, but it is difficult to insure acid except free of claim for damage but including loss by washing overboard or jettison. The ordinary on-deck rate varies from two to five times the under-deck, depending upon the type of cargo and the length of the voyage.

Under the York-Antwerp rules, on-deck cargo contributes in general average, but is not contributed for. It is easy to understand the reason for this rule if one considers that jettison of cargo for the benefit of all interests is customarily made good as a general average sacrifice, and on-deck cargo would, in almost all cases of stress, be thrown overboard immediately as a precautionary measure, thus subjecting the under-deck cargo to a charge which is due more to the manner of the stowage than to its being a sacrificial measure. On the other hand there is no reason why on-deck cargo should not contribute in general average if expenses or losses are incurred from which the on-deck cargo benefits. The ordinary on-deck insurance includes coverage against general average and salvage charges.

The danger of on-deck cargo breaking adrift, and its susceptibility to loss or damage because of its exposed position, makes it necessary that strict rules be made for the proper stowage of such cargo. And that is why we find that underwriting boards lay down specific methods for loading and securing deck-laden goods.

Deviation Permit

THE following clause is now being used by the United States Shipping Board in its bills of lading:

"If vessel be prevented from reaching her destination by quarantine, shallow water, blockade, conditions of weather, surf, ice, war or civil disturbances; or, if it becomes impracticable to discharge the goods at destination on account of congestion, strike, labor difficulties, or otherwise, occurring before or after receipt of goods by the carrier, ves-

sel shall have liberty, without proceeding to or near port of destination, to proceed to and discharge the goods at a nearby available strike free, uncongested port. Notice of discharge of the goods shall be dispatched to consignee, if named herein, otherwise to the shipper, and such discharge shall be deemed a complete delivery under this contract and full freight shall be deemed earned. All expenses incurred on the goods shall be a lien thereon."

This is all very nice, but there is an insurance angle to it that ought not be overlooked. The ordinary marine policy contains a clause excluding the risk of strike and riot, and the insurance might well be invalidated by the operation of the clause above given, which grants the privilege to the carrier in event of congestion at one port to discharge at a nearby port. Despite the deviation clause of the marine policy, if the deviation is caused by some such reason as a strike, which is expressly excluded from the policy, the underwriters in all probability would not be liable during the period of deviation.

Coffee Cargo Swelled

THE Pacific Mail steamer *Cuba* which went ashore in the Pacific off San Miguel Island a month or two ago was finally abandoned with a loss of \$400,000. A peculiar thing about this casualty is that the cargo of coffee swelled greatly through action of the water. Underwriters have had frequent experience of damage to vessels due to the swelling of grain cargo but it is rare indeed for such damage to be caused by the swelling of coffee. Three or four years ago a case was reported where the seams of a wooden schooner bound from Brazil to New York were opened by this cause, but that was the first case of the kind of which there was any knowledge. It is now claimed that the destruction of the *Cuba* was not owing so much to the pounding of the waves as to the swelling of the cargo of coffee which caused the hull and decks to be forced out of line.

Pilferage Bureau Popular

MARINE insurance men at New York have faith in the success of the proposed Pilferage Information Bureau, provided that all who now profess interest in its organization will adequately support it after it has been started. They believe it will aid materially in controlling and reducing theft and pilferage losses at this port. The underwriters have been represented at the meetings of the provisional committee and one of them, H. H. Reed, is a member of that committee which, as is known, has been invited to continue its work and draft by-laws and nominate officers in order that the Bureau may become a concrete fact and begin to function at the earliest possible moment. Through such a clearing house, insurance and shipping interests, it is believed, could secure the maximum amount of information for the tracing and punishment of cargo thieves. It is not planned to employ either watchmen or detectives, but merely clerks who shall assemble and classify the information turned in by Bureau members or from any other source. Every report of a theft is to be forwarded immediately to each member and thus solidify a strong and organized support behind the movement.

Report on Talin (Reval)

A DIGEST of information on the port of Reval has been prepared by the Board of Underwriters of New York, in which the following interesting data appear: Vessels drawing thirty feet can pass in and out. No tide. The total length of the berthing space is about 7,800 lineal feet, the depth along the quays being from 18 to 30 feet. All quays are provided with normal gage railway, and two quays are provided with a narrow gage railway in addition. Cargo

U. S. S. West Virginia Goes Into Commission This Month

**Last of the Electrically Driven Battleships Completed at Newport News
—Propelling Machinery Supplied by the General Electric Company**

THE *West Virginia*, last of the battleships to be built by the United States Government under the Washington Arms Conference limitation and sixth to be equipped with electric drive, will leave the yards of the Newport News Shipbuilding and Dry Dock Company about December 1 to go into service under the command of Cap-

The vessel is 624 feet long, 97 feet beam at the waterline, and displaces 32,600 tons. She is expected to make 21 knots and has a cruising radius of about 10,000 miles. She will burn oil, her fuel capacity being about 1,400,000 gallons.

ELECTRICAL MACHINERY

The *West Virginia* is electrical throughout. Her main propulsion machinery consists of two Curtis steam turbine-generators, designed to develop 12,600 kilowatts at 2,150 revolutions per minute. These supply power to four 8,000 horsepower General Electric induction motors, directly connected with the four propellers and turning at 177 revolutions per minute. The motors are 12 feet in diameter and weigh 62 tons.

U. S. S. West Virginia, the Last of the American Battleships to Be Commissioned

tain Thomas J. Senn. She will be a sister ship to the *Maryland* and the *Colorado*.

Carrying eight 16-inch guns, the *West Virginia* will be the most powerful fighting craft in the world. She will have a secondary battery of fourteen 5-inch guns, four 3-inch anti-aircraft guns and two underwater 21-inch torpedo tubes.

The two turbine generators, supplied with steam generated by eight oil-burning boilers, can be run independently. Either is capable of driving the ship up to a speed of about 17 knots. The power generated by them is used for no other purpose than propulsion, electrical current for other needs being generated by six 300-kilowatt generators and two 400-kilowatt Diesel generators.

can be loaded or discharged directly from the vessel into railway trucks, or vice versa. For lifting heavy cargo five floating steam cranes are available.

Failure of Condenser Tubes

(Continued from page 773)

be quite confidently stated that no facts whatever supported by any records of experience exist by which the observable or measurable properties of a condenser tube beyond those incident to good workmanship can be predictably related to its service endurance. The effect of such specifications, therefore, can only be to increase the ultimate cost of condensations. The American Society for Testing Materials has adopted specifications which it is believed comprehensively cover all the requirements of the best manufacturing

practice and their unanimous acceptance by both producers and consumers alike could have no other result than to bestow on the industry all of the benefits incident to the introduction of standards into a situation in which they have had no previous existence.

In conclusion the writer wishes to point out the desirability of and necessity for a thorough investigation of condensers and the conditions under which they are operated as a means of providing data looking to the solution of the problem of tube failure. If in the presence of adequate records of temperatures, water velocities, shut downs, cleaning procedure, etc., failed tubes are withdrawn as they give out and the character of corrosive action involved in each case determined, much more progress will be made than through any amount of speculation based upon the physical and other properties of the tubes themselves.

Questions and Answers Relating to Naval Architecture and Marine Engineering

Conducted by James L. Bates, Naval Architect, and W. B. Newton, Marine Engineer

This department is maintained for the purpose of answering all questions relating to ships and their machinery. All inquiries should bear the name and address of the writer. Anonymous communications will not be considered. The identity of the writer, however, will not be disclosed unless the editor is given permission to do so.

Figuring Indicated Horsepower of Compound Engine

Q. (1,218).—Referring to Q. (1,198) in the June issue: "How to calculate Indicated Horsepower when Mean Pressure of Cylinders Are Unknown" refers to a three-cylinder triple-expansion engine. Could the same quantities be used for calculating the indicated horsepower of a two-cylinder compound engine except for the value of E? or—How could the indicated horsepower of a two-cylinder compound engine be found without knowing the mean effective pressures in the cylinders?

Diameter high pressure cylinder $17\frac{3}{4}$ inches or 18 inches;
Diameter low pressure cylinder 38 inches;
Stroke, 28 inches;
Revolutions per minute, 90;
Steam pressure, 175 pounds per square inch; vacuum, 24 inches.

A. (1,218).—Use the same nomenclature as in the answer to Q. (1,198) in the June issue.

$C_h = 60$ percent. This value has been assumed and varies from 50 to 70 percent for this type of engine.

$A_h = 247.5$ square inches.

$A_1 = 1,134$ square inches.

$$R = \frac{A_1}{C_h \times A_h} = \frac{1,134}{.60 \times 247.5} = 7.638$$

Hyp. log R = 2.0331.

P = 175 pounds absolute. This allows for 15 pounds drop between the boiler and engine steam chest.

L = 2.33 feet.

R.P.M. = 90.

S = 419.4.

p = 5 pounds. This value should be about 2 pounds higher than that corresponding to vacuum. It would have been better in my answer to question (1,198) to have used 4 pounds instead of 3.

$$P_m = P \times \frac{1 + \text{hyp. log } R}{R} - p = 175 \times \frac{1 + 2.0331}{7.638} - 5 = 64.5$$

E = .60 to .67 for this type of engine. Use .635.

$P_r = P_m \times E = 64.5 \times .635 = 41.$

$$\text{I.H.P.} = \frac{P_r \times S \times A_1}{33,000} = \frac{41 \times 419.4 \times 1,134}{33,000} = 591.$$

Fit of Propeller on Shaft

Q. (1,226).—Should a propeller be set up hard on the shaft taper or made an easy fit (secured with key and nut) for convenience in removal?
MACHINIST.

A. (1,226).—A propeller should be set up hard on the shaft taper, either by driving on or by the use of a sledging wrench, depending upon the size of the job, to guard against danger of backing off and to relieve the load on the propeller key. A propeller becoming loose on its shaft, even though the nut was locked, would soon batter the key to

pieces. In naval practice, contractors are required to furnish propeller sledging wrenches.

Propellers as a rule are drilled and tapped for strong-back bolts for use in pulling them off.

Strength of Boiler Water Gage Glass

Q. (1,227).—Why doesn't the water gage glass on a boiler burst from the pressure of the steam?
J. W. D.

A. (1,227).—The stress per square inch on a gage glass due to the pressure alone is low, as will be seen from the following:

Inside diameter of glass	$\frac{1}{2}$ inch
Thickness of glass	$\frac{7}{64}$ inch
Boiler pressure, pounds per square inch gage.....	200
	$\frac{200 \times .5}{.1094 \times 2} = 457$

Assuming a tensile strength of 3,500 pounds per square inch gives a factor of safety of 7.66. This is a larger factor than the 4 to 4.5 usually allowed for Scotch boiler construction. It will therefore be seen that the glass from a boiler pressure standpoint is stronger than the boiler. There are, however, other factors entering into the manufacture of gage glasses which must not be neglected such as resistance against sudden temperature changes due to cold air coming in contact with the hot glass; and corrosion of glass due to steam, feed water and boiler compounds. Strains are often set up in the glasses, which can not be taken care of by calculations, due to misalignments of glass and fittings when assembling.

Influence of Ash in Coal on Boiler Efficiency

Q. (1,225).—What is the influence of the percentage of ashes in coal on the boiler efficiency?
O. K.

A. (1,225).—There are two methods of figuring boiler efficiency:

1. Efficiency of the boiler =
Heat absorbed by boiler per pound of combustible

Calorific value of one pound of combustible

2. Efficiency of boiler, furnace and grate =

Heat absorbed by boiler per pound of coal

Calorific value of one pound of coal

The first is based upon the combustible content of the coal and is preferable as a standard of comparison for all tests as well as being the one usually understood when boiler efficiency is referred to. The second is based upon dry coal and permits of comparison of the combined boiler, furnace and grate performance.

Ash consists of the non-combustible residue left after complete combustion has taken place. It not only is waste material in the coal but it carries away with it a considerable amount of unburned carbon when cleaning fires. The amount of ash in a coal is extremely important to know because of the effect of its fusibility upon the steaming quality of the

coal. As the ashes fuse, clinkers are formed on the grate which together with the unfused ashes clog the grate, cutting off the air supply to the fire thus necessitating frequent cleaning and retarding combustion to such an extent that the boiler efficiency becomes rapidly impaired.

It may be seen from the foregoing that while the calorific value of coal is decreased by the presence of ash and though the heat absorbed by the boiler per pound of coal is theoretically decreased probably in the same proportion, yet in reality as the percentage of ash is increased, its heating value decreases in more rapid proportion thus lowering the boiler's combined efficiency.

LETTERS TO THE EDITOR

Weight of Engines in M. S. Crux

TO THE EDITOR:

COPENHAGEN, Denmark.

We have studied the article "Europe Developing New Types of Diesel Engines" in your October issue with much interest, and note the statement that the less weight of the machinery of M. S. *Crux* is only achieved by adopting "the high speed of 145 to 150 revolutions per minute."

We cannot admit you are right and only draw your attention to the fact that the same number of revolutions was used in several of our older motorships as M. S. *Suecia*, M. S. *Pedro Christophersen*, M. S. *Arator*, etc., where the weight of the machinery was considerably greater than for the M. S. *Crux*.

According to our experience this number of revolutions has always proved suitable in the ships where it has been used.

Cooperation Between Owner, Builder and Operating Personnel

NEW YORK, N. Y.

TO THE EDITOR:

At the present time we hear much about the high cost of operating American ships, and the importance of saving "here and there." Much is expected of the marine officer in the accomplishment of this desired end. As a general rule, the officer does all he can and is fully alive to this important matter. He is only too anxious to cooperate with the owner, as it means his very bread and butter in plain words.

If the owner claims a handicap, and no doubt he does, when comparing with certain European standards, the ship's officers are also put under a handicap by their unskilled and ever-changing crews. They have continuously to teach green crews and very seldom realize a fair return on their investment as the men generally don't stay long enough on a ship to master the profession thoroughly or to be of any material help and assistance. Men nowadays don't seem to realize the importance of learning a trade thoroughly nor to have the patience to do so. It is a rarity to find a mechanic of any trade among the crew or even among the engineers. Again the relations of the ship's personnel and officers are not always of the best; in some cases amounting to open hostility. Often a senior officer is blamed for every little mistake made by those under his charge, and long years of service and loyalty are rewarded by a dismissal after spending the best part of his life in a firm's employ. A lot could be done, if officers and their employers could get better acquainted and meet each other halfway. Loyalty begets loyalty and it is the human factor, after all, that decides profit and loss in any line of business.

Secondly, there is a great field for improvement in designing and installing the various auxiliaries of the ship's power plant, whereby the cost of upkeep would be materially lessened and at sea made easier. If auxiliaries were only installed in accessible places, it would not be necessary, as is too often the case, to dismantle about half the engine room in order to remake some pipe joint. It is only a matter of using the allotted space to the best advantage instead of shoving everything in one corner and wasting the other. A good many ships have a fairly complete machine shop to take care of routine work, but often in such a place that it is almost impossible for a man to work there on account of abnormal heat and poor ventilation, so really, considering the cost of installation, it becomes a liability instead of an asset.

There is a great field for improvement in the merchant marine—above all in closer cooperation and good will between owner, builder and operating personnel to the mutual benefit of all concerned.

New York.

MARINE ENGINEER.

NEW BOOKS

The Lookoutman

Reviewed by Carl E. Petersen
Naval Architect, United States Lines

THE LOOKOUTMAN. By Captain David W. Bone. Size, 8¾ by 6 inches. Pages 220. Illustrations, 22. New York, 1923: Harcourt, Brace & Company.

To those who "go down to the sea in ships" or who are otherwise engaged in the design, building or operating of ships, the latest book, "The Lookoutman," by Captain David W. Bone, master of the Cunard liner *Tuscania* will instantly appeal. While the book is primarily intended to familiarize the layman with the general types comprising the present day tonnage it is so full of information concerning these types, their functions and their behavior at sea that no technical man who loves his profession should miss an opportunity to read it.

The book consists of fourteen chapters: 1, "Getting Under Way"; 2, "The Great Ships"; 3, "Mail Liners"; 4, "Intermediate and Cargo Liners"; 5, "Tramp Steamers"; 6, "Turret Ships and Oil Tankers"; 7, "Steam Yachts and Cross-Channel Express Steamers"; 8, "Coasters and Short-Sea Traders"; 9, "Fishing Craft"; 10, "Pleasure Steamers"; 11, "Dredgers and Attendant Craft"; 12, "Tugs and Port-Service Vessels"; 13, "Piping Down," and "Glossary of Sea Terms." The book is well illustrated with sketches and small scale silhouette profiles. There is also appended a splendid glossary of sea terms for the uninitiated.

Perhaps no other recent author has explained the sentient bond existing between man and ship as has Captain Bone in his introduction, which reads as follows:

"The attitude of the sailor toward the ship is sufficiently peculiar to call for comment. To him, a seaworthy vessel is quite unlike any other structure fashioned by man. He sees her as a sentient creature with a decided personality; a spirited rover of wide seas, possessing qualities no less resourceful and adventurous than his own; a creature to be humored and admired (or perhaps forced and cursed) as her tricks and moods and tempers become revealed to him. For this belief, the circumstances of her birth are sufficient warrant. Conceived in the studious and creative mind of her designer, erected in patient exactitude by her builders, trimmed and riveted and fashioned into a complete and wonderful whole by the skill and craftsmanship of her artisans, she comes to her sea world with sponsors and guarantors enough. Surely, some intangible essence, some spirit of all these labors at her birth—the conceptive thought, skilled direction, the sweat and strain of toiling hammermen—must pass into her shapely hull as it grows upon the stocks. And when, at length, she is named and launched and floats upon the

river reach—a noble vessel, powerful, buoyant, inspired by the stir and circumstance of her baptism—the cheering shipyard workers must feel that a part of themselves goes out abroad with this wonderful product of their hands. It is this conception of personality and character in a ship that the sailor accepts. He may call her brute or lover, he may beat and drive her or handle her with tender care, but she is never a senseless machine to him. The reader is entreated to tolerate this simple faith."

In the second chapter listing the ten great liners or "Sea Queens" are included our own *Leviathan* and *George Washington*. The other vessels named, the *Majestic*, *Berengaria*, *Olympic*, *Homeric*, *Aquitania*, *Mauretania*, *Paris* and *Belgenland*, together with our own are chosen "not merely because of their great size, but rather by virtue of the completeness and safety of their performance."

A noteworthy statement which designers of vessels may well bear in mind is—"It is a fact, peculiar and perhaps unaccountable, that the most graceful ships are the most sea kindly in a gale."

Regarding the mail liners as apart from the leviathans of the ocean, Captain Bone has this to say: "As it seems unlikely that any new ships of the greater class will be laid down in the near future, the mail liners may be looked upon as the heirs apparent to the maritime thrones of the nations." The author makes the following remarks on the 535-footers:

"At a first glance, one is inclined to dismiss her as unworthy of sailorlike attention; she appears to be unnecessarily odd in her proportions; her peculiar features are aggressively at variance with all the accepted standards of a fine ship design. But such a view would be unfair to an excellent, if unorthodox, intermediate liner. She is distinctly a product of the war, and German submarines are to be blamed for her departures from the symmetry of conventional ship architecture. If she could be seen from the point of view of her designer, who was concerned to present a distorted outline to the periscopic survey of an enemy submarine commander, one would doubtless form a better and more kindly estimate of the skill with which this requirement, at least, has been met. She was originally built as one of a transport fleet for the carriage of United States troops, but these vessels were not completed when the war ended. When under construction, she was converted into a cargo carrier of large capacity with very fine accommodations for a comparatively limited number of passengers. One of her peculiar (war-time) features is the form of the stern, an ingenious copy of the bow structure of the ship, and one which, together with the upright setting of masts and funnels, made it very difficult for a distant observer to determine whether she was bound east or west. But for this arrangement (which one would hesitate to term seemly) her hull has fine lines and the great flare of the bows is particularly noticeable. Her passenger accommodation is in a box-like superstructure amidships and is perhaps more ample and convenient than that of vessels having more graceful and less rectangular deck erections. She has a speed of about fifteen knots (speed erroneously stated, should be 18 to 19 knots) and is altogether a strong and seaworthy vessel."

At the present time with very much depressed shipping conditions in this country, full significance should be taken of the author's statement:

"The laying down of the great emergency fleet, * * * * * was a new adventure for Uncle Sam. For years he had been lying on his oars, content to let other nations do his 'trucking.' In competition with the cheaper workmanship, cheaper materials, cheaper manning, of other maritime nations, he could see little or no profit in an adventure on the deep. Came the war, and the perspective of his vision altered rudely. The film of 'profit and loss' dissolved, showing the ships as one of the great material assets of a nation. The cry was for ships, for ships at any price! Much can be done when costs are in the clouds, when all considerations of profit are blown over the horizon before the blast of war. The tremendous augmentation of American tonnage that astonished the world and did so much to end the war came when Uncle Sam put aside his 'landward' toys and commenced to ply the oar again."

The "oil tanker" is considered by the author as being probably the nearest approach to the unsinkable ship that has yet been conceived by the naval architect, and in her he has designed a ship that combines great stability and power, excellent speed and ease of maneuver, with a capacity to carry a large burden.

Finally the book is highly informative and very interesting and the author is to be commended on the pleasing manner in which he has presented a broad and varied subject.

DIESEL AND OIL ENGINE HAND BOOK. By Julius Rosbloom. Size, 5½ by 7 inches. Pages, 376. Numerous illustrations. Los Angeles, Cal., 1923: The Technical Publishing Company.

This book is a compilation of a quantity of more or less disconnected data relative to Diesel and oil engines, together with some very short and elementary explanations of the principles of thermodynamics, indicator practice and electrical measurements. The main value of the book is embodied in a considerable amount of information, in the form of questions and answers, relative to the operation of internal combustion engines.

PERSONAL MENTION

H. H. BENEDICT, formerly traffic manager of the Green Star Steamship Corporation, is now New England agent of the Pacific Mail Steamship Company.

CHARLES MACGREGOR has left the Shipping Board staff at 45 Broadway, New York, and returned to his old connection with the Export Steamship Company.

W. S. WILKINSON, technical manager for some time past at the New York office of the Bethlehem Shipbuilding Corporation, has been transferred to the Moore plant at Elizabethport, N. J.

HERBERT N. THOMAS, formerly manager of China Mail Steamship Company, is now on the staff of the Robert Dollar Company, under Hugh McKenzie, head of the passenger department. Prior to joining the China Mail, Mr. Thomas was with the Pacific Mail Steamship Company.

F. B. WEBSTER, who recently resigned the position of editor of MARINE ENGINEERING AND SHIPPING AGE to become business manager of *The Marine Journal*, is a graduate of the Massachusetts Institute of Technology of the class of 1901 in naval architecture and marine engineering. Mr. Webster began his career as a ship fitter in the yard of the Fore River Ship and Engine Company, which is now a part of the Bethlehem Shipbuilding Corporation, Ltd. He worked in the drafting rooms of the Puget Sound Navy Yard, the Moran Company and the Seattle Dry Dock and Construction Company until early in 1914, when he went to the Bureau of Construction and Repair, Navy Department, Washington, D. C., to take a position in the research and scientific department. He resigned from this position in 1917 to become naval architect for the Liberty Shipbuilding Company and subsequently naval architect and chief designing engineer for the Concrete Ship Section of the Emergency Fleet Corporation. After the armistice Mr. Webster compiled the "Shipbuilding Cyclopedia" for the Simmons-Boardman Publishing Company, subsequently becoming editor of MARINE ENGINEERING AND SHIPPING AGE.

F. B. Webster

Frank J. Shipman, President, American Marine Association

Marine Association Elects Officers for the Coming Year

ON Saturday, November 10, the annual meeting of the American Marine Association was held in the Waldorf-Astoria Hotel, New York City. Frank J. Shipman, of the Texas Company, was elected president for the coming year, succeeding Colonel E. A. Simmons. The other officers elected were: Vice-president, Edward A. Colson, Babcock & Wilcox Company; treasurer, James Plummer, Newport News Shipbuilding Company.

The members of the executive committee are: H. F.

D. G. HODGES has been appointed assistant to the general manager of the Alabama Dry Dock & Shipbuilding Company of Mobile.

R. T. GORDON has been appointed New York district manager of Dean Brothers Company of Indianapolis, manufacturers of pumping equipment.

J. M. HARTMAN, in charge of docks and wharves for the Shipping Board, has resigned, effective December 1, to become general manager of the Boston Tidewater Terminal Company.

RALPH L. LOVELL, formerly chief engineer for the Emergency Fleet Corporation, has been appointed a sales engineer for the Power Specialty Company, handling Foster superheaters and watertube boilers.

EDWARD HANNA, formerly vice-president and general manager of the Hanlon Shipbuilding & Dry Dock Company of Oakland, Cal., recently became manager of the Bethlehem Shipbuilding Plant at San Francisco.

Alexander, Pacific Steamship Company, Seattle; S. I. Cooper, Southern Pacific Company, New York; James S. Milne, Todd Shipbuilding Corporation, New York; Colonel Edward A. Simmons, Simmons-Boardman Publishing Company, New York; A. E. Allen, Westinghouse Electric & Manufacturing Company, New York; W. M. MacFarland, Babcock & Wilcox Company, New York; W. E. Sawhill, editor *Marine Review*, Cleveland; Captain W. H. Stayton, Baltimore Steamship Company, Baltimore.

The executive committee will meet later and select a secretary to succeed K. Warren Heinrich, who has resigned, effective December 1.

Edward A. Colson, Vice-President, American Marine Association

HARRY MEACHEM, formerly New York representative for the Dean Bros. Pump Company, has been appointed vice-president and general manager of the Rider-Ericsson Engine Corporation and the Delamater Iron Works.

F. J. O'CONNOR, of the Donovan Lumber Company, was elected president of the Shipowners' Association of the Pacific Coast, succeeding R. W. Myers of the Hobbs-Wall Lumber Company, at the annual election of officers.

GEORGE O. WALTON, who has been in the steamship and railroad business for many years, has been appointed district passenger manager of the United States Lines, in charge of the territory comprising New York State, southern Connecticut and New Jersey north of Trenton.

CAPTAIN ELMER E. CROWLEY, formerly of the Coastwise Transportation Company of Boston, has been appointed general manager of the Susquehanna Line, Inc., 2 Stone street, New York, to succeed J. B. Austin, Jr., deceased. Captain Crowley has been one of the most active and successful of New England steamship executives.

The Month's Shipping and Shipbuilding News in Brief

Shipyard, Steamship and Port Activities and Other Notes
of Interest in All Branches of the Marine Industries

Catalina Island Line to Build New Passenger Steamer

THE Wilmington Transportation Company, operators of the Catalina Island line of steamers plying between Los Angeles and Avalon, has decided to build a new boat for this service, according to official information obtained by MARINE ENGINEERING AND SHIPPING AGE. J. R. Patrick, president, and William W. Rigley, Jr., chairman of the Board, were in conference at Chicago, Ill., early last month with other company officials and took up, among other things, the question of a new vessel. The specifications have not yet been completed, although it is understood that the steamer will have a length of about 300 feet with a 50 foot beam, to be driven by twin triple expansion engines.

The proposed new steamer will be equipped with all modern features for the two hour run from Los Angeles harbor to Catalina Island and the acquisition of this boat will give the company four ships in this service.

Ship Construction Program Reports Are Again Discussed

REPORTS were again current in marine circles during the past month that the Union Tank Ship Corporation of New York is planning to enter the oil carrying trade on the west coast with eleven new motor tank ships costing approximately \$12,000,000 and pipe lines and leading stations to cost about \$1,000,000. The announcement is credited to Herbert A. Blumenthal, president of the corporation, and refers to a contract with the Sun Shipbuilding Company for the construction of these ships.

Investigation by MARINE ENGINEERING AND SHIPPING AGE disclosed the fact that the Union Tank Ship Corporation has an office at 25 Broadway. From the Chester, Pa., offices of the Sun Shipbuilding Company it was learned that the yard has no contract with the corporation for the proposed vessels. The proposition, it was stated, has been talked about for some time but information as to definite action is lacking. It is understood that the new tankers were to be of the steamship *Bidwell* type. This vessel is one of three ships taken over from the government by the Sun company and converted to Diesel drive. The ship is now at sea, under charter.

Charles Ward Low Bidder for Pipe Line Dredge

Chas. Ward Engineering Works, Charleston, W. Va., with a price of \$427,000, submitted the lowest price for the construction of one 15-inch hydraulic pipe line dredge at the U. S. Engineer Office, Chicago, Ill., on November 15.

Bids Asked for Matson Liner

THE Matson Navigation Company of San Francisco has asked for bids for the construction of a fast passenger and freight liner, according to reports from the West Coast. It is understood that the proposed liner will have accommodations for about 500 first class passengers and that eastern and western shipyards will submit figures on the contract.

F. D. Tenney is president of the company, W. H. Roth, manager, and A. C. Dietrix, assistant manager. The new vessel will probably be put on the San Francisco-Honolulu run.

Passenger Boats Are Planned by New MarMack Company

THE MarMack Transportation Company, Inc., with general offices at 246 Wood Street, Pittsburgh, Pa., has been organized under the laws of the State of Delaware with a capital stock consisting of 10,000 shares of common without nominal or par value and 5,000 shares of preferred stock having a par value of \$100 each. Harry F. Martin is president of the Corporation and Captain James A. McDavid is secretary and treasurer.

The company was organized for the purpose of operating a line of steam vessels of the passenger, freight and excursion type, the excursion vessels to be run to and from the amusement park to be owned and operated by the company in the vicinity of Pittsburgh, Pa. The passenger and freight business is to be between Pittsburgh, Pa., and New Orleans, La. It is the idea of the company to build steamers of the side wheel type, at least one of which is to be large enough to accommodate 5,000 persons in the excursion trade and 500 persons in the passenger trade.

Coastwise Shipping Laws Will Not Be Extended to the Philippines

President Coolidge has no present intention of extending the application of the coastwise shipping laws to the Philippines, it was stated at the White House on November 23. The President has received a report from the State Department which expresses doubt as to the propriety of doing so because of the provisions of certain treaties.

Marine Congress Is to Become a Permanent Body

At a meeting of the Central Committee of the American Marine Congress, on November 9 at the Waldorf-Astoria Hotel, New York, a sub-committee of the Marine Congress was appointed to draft a workable plan for the permanent organization of the Congress.

The sub-committee is composed of the following:

Myron W. Robinson, former president American Manufacturers' Export Association, chairman.

Winthrop L. Marvin, vice-president American Steamship Owners' Association.

C. H. Potter, president United States Ship Operators' Association.

O. E. Bradfute, president American Farm Bureau Federation.

Captain John F. Milliken, secretary of the Neptune Association.

E. E. Spafford, Commander, New York Department, American Legion.

H. A. Magoun, president Atlantic Coast Shipbuilders' Association.

The first meeting of the sub-committee was held at the offices of Colonel E. A. Simmons, former president of the American Marine Association, at 30 Church street, New York on November 21, when plans to consolidate the various shipping organizations throughout the country into the American Marine Congress, to unify and strengthen the efforts now being made to promote the cause of American shipping, were discussed.

As a preliminary step toward the combination the committee has undertaken a canvass of sentiment among existing associations. When this survey is completed another conference will be called at which, if the plan is approved, a constitution and by-laws will be formulated and further steps will be taken to create an effective organization.

The general sentiment at the committee meeting was that the work of educating the public on marine questions, and bringing about co-ordination of all branches of industry on a shipping policy for the country, would be facilitated by a strong central body. Objections to the existing system showed that the separate organizations are frequently working at cross purposes, their efforts are sometimes dissipated for this reason and a centralized association would be more effective. Among the bodies affected by this plan would be the American Marine Association, the Atlantic Coast Shipbuilders' Association, the National Merchant Marine Association and others.

Bids for Steel Towboat Open Dec. 19

The First and Second Mississippi River Districts, 1006 McCall Building, Memphis, Tenn., will receive sealed proposals for furnishing one stern-wheel steel towboat, until 11 A. M., December 19, 1923.

First Annual Banquet of American Marine Congress at the Waldorf-Astoria Hotel, New York, November 8

Construction of 25 Barges Planned

THE construction of 25 new steel barges, to replace wooden barges on the Warrior River, Ala., is under consideration by the U. S. Government Warrior River Barge Line, according to latest advices.

In addition to the 15 new wooden barges, under consideration, the West Kentucky Coal Company of Sturgis, Ky., plans to build 15 additional boats, or a total of 30 in all. The coal company will build all the barges at its ways at Paducah, Ky.

Steel Pontoon Bids

At the opening of tenders by the U. S. Engineer Office, Rock Island, Ill., the Dubuque Boat & Boiler Works, Dubuque, Iowa, submitted the low price for twenty steel discharge pontoons, 38 by 14 by 3 feet, and their bid was recommended for acceptance. Two companies submitted proposals as follows:

Dubuque Boat & Boiler Works, Dubuque, Iowa, \$44,840.

Rock Island Bridge & Iron Works, Rock Island, Ill., \$47,200.

Dravo Gets Barge Work

The Pan-American Petroleum Company, of New York, has awarded a contract for a steel tank barge to the Dravo Contracting Company, Pittsburgh, Pa. The boat will have a length of 200 feet, beam 40 feet, depth 10 feet 6 inches.

The Dravo Company also has a contract for two additional barges, each 120 feet long by 28 feet 6 inches wide and 6 feet 6 inches deep.

Terminal and Dock Project

P. S. Gilchrist, Charlotte, N. C., is reported as having in preparation plans for a phosphate terminal and new dock for the U. S. Export Chemical Corporation, Krause Building, Tampa, Fla. It is understood that the project will cost approximately \$400,000.

The Atlantic Deeper Waterways Association has chosen Newark, N. J., as next year's convention city.

Reconditioning of Three Ships Awarded Federal, One to Staten Island and One to Navy Yard

THE Shipping Board has awarded contracts for reconditioning of the transports *Marne*, *Cantigny*, *Ourcq*, *Tours* and *Aisne* to the Federal Shipbuilding Company, of Kearny, N. J., the Staten Island Shipbuilding Company, of Staten Island, and the Brooklyn Navy Yard, Brooklyn, N. Y. The work on the *Cantigny*, *Marne* and *Tours* has been awarded to the Federal yard for \$1,004,650, for completion within 75 and 100 and 125 days, respectively. The Staten Island yard received the work on the *Ourcq* for \$389,520, to be completed in 100 days

and the Brooklyn Navy Yard obtained the work on the *Aisne* for \$390,000, to be completed in 90 days.

Eleven shipyards submitted bids and two navy yards offered estimates, all of which were taken to Washington by Mr. Gibbs for the final decision.

The ships are to be refitted for cargo and passenger service, the principal items in the specifications providing for the installation of approximately 45,000 feet of new refrigeration space in each vessel and the removal of such material and equipment as was necessary for the putting of the steamers in service as troop ships.

Bids Open December 1 at Mobile for Five Barges

The United States Engineer Office, at Mobile, Ala., will open bids at 11 A. M., December 1, for the construction and delivery of five steel barges. Each boat is to have a length molded of 100 feet, beam 25 feet, depth 5 feet, and to be constructed with cargo boxes, two of the barges being delivered afloat at Lock A, Cumberland River, forty miles below Nashville, Tenn., and three barges delivered at Mobile, Ala.

Southern Company Planning Fleet of River Craft

According to information obtained by MARINE ENGINEERING AND SHIPPING AGE, the American Rolling Mill Company, Ashland, Ky., plans to construct private river terminals at Zanesville, Ohio, on the Muskingum River, and at Ashland, Ky., on the Ohio.

It is said the company plans a large fleet of towboats and barges for its own use.

G. M. Chelf, formerly of the New York office of the Black Diamond Steamship Corporation, is now in charge of the Philadelphia branch of the same line.

Marine Men Witness Test of New Bethlehem Oil Engine

ABOUT one hundred naval architects, marine engineers and ship operators visited the Bethlehem Works of the Bethlehem Steel Company on November 22, on the invitation of the officials of the company, to inspect the new 2,900 brake horsepower Bethlehem two-cycle, single-acting marine oil engine. The engine, designed by Arthur West, has been run an equivalent of 50,000 sea miles without replacements of any sort and without any wear being apparent on the engine.

New Towboat Building

The Evansville Sand & Gravel Company is having a new towboat built at the Evansville Ways Company, Evansville, Ind. The boat is 112 feet long, 24 feet beam, depth 4 feet 3 inches. She is to be equipped with two boilers and also compound engines with 12-inch cylinders and 6-foot stroke.

John Steinman, superintendent of the Buffalo yard of the American Shipbuilding Company, has been appointed superintendent of the Cleveland yard of the company, to fill the vacancy caused by the resignation of the present superintendent.

Current American Shipbuilding

On October 1, 1923, American shipyards were building or under contract to build for private shipowners 226 steel vessels of 160,351 gross tons, compared with 152 steel vessels of 140,929 gross tons on September 1, 1923.

There were 8 wood vessels of 1,004 gross tons building or under contract to build for private shipowners during the

same period, compared with 11 wood vessels of 1,270 gross tons on September 1, 1923.

Following is a summary of reports of shipyards to the Bureau of Navigation, Department of Commerce, showing the number and gross tonnage of steel and wood vessels of 100 gross tons and over under construction or contract for private owners on October 1, 1923:

Companies	Steel		Wood	
	No.	Gross tonnage	No.	Gross tonnage

Million for P. & R. Piers and Machinery at Port Richmond

IT has been announced that the Philadelphia and Reading Railway Company proposes to spend approximately \$1,000,000 for new machinery, additional piers and other ore-handling equipment at Port Richmond. This equipment is in addition to the \$3,000,000 grain elevator and \$1,000,000 to be spent for a McMyler coal-dumping apparatus.

Since the erection of the present ore pier at Port Richmond twelve years ago the ore plant has had a monthly average capacity of 36,067 tons. During the present year, however, this business has developed so rapidly that additional facilities are necessary.

The plans include the enlargement of Pier 14, and the installation of another set of ore-handling machinery, at an estimated cost of \$915,000. It is said that when this machinery has been installed the machinery on the present pier will be overhauled and renewed as business permits. A pier also will be built south of Pier A, to relieve Pier 14. The approximate cost of this work will be \$600,000. Extensive work also will be done on the boiler house, including the installation of a new 1,000-horsepower boiler.

TRADE PUBLICATIONS

UNDERFEED STOKERS.—The Westinghouse Electric and Manufacturing Company, Stoker Department, South Philadelphia Works, Philadelphia, Pa., describes in some detail the design of a new model multiple retort underfeed stoker. A prominent feature of the new design is the positive control of the contour of the fuel bed. Another feature is the agitating element mounted across the lower end of the stoker adjacent to the retorts which provides a means for maintaining a minimum loss due to combustible in the refuse. The main structure of the stoker is built with heavy supporting members to assure perfect alinement of the parts as well as easy access to an individual part or any group of parts.

WESTINGHOUSE MARINE LOG.—The *Westinghouse Marine Log*, which was initiated as an internal house organ by G. W. Froebel, recently appointed manager of the Westinghouse Marine Department, has made its first appearance for general circulation in marine circles, being distributed to naval and marine officials, shipowners, ship operators, naval architects and port engineers. This issue, which was first distributed at the Marine Exposition, contains a leading article on the "Diesel Electric Drive" by W. E. Thau.

Other articles were written by W. B. Flanders, H. C. Coleman, C. Schmidt, C. C. MacMillan, H. M. Southgate and William H. Easton. Articles are also included, written outside of the Westinghouse organization entirely, by Captain Richard H. Leigh, U. S. N., former commander of the U. S. S. *Tennessee*, and George Pierce of William Cramp and Sons Ship and Engine Building Company.

AIR HOISTS.—Air hoists, patented and built by the Hanna Engineering Works, Chicago, Ill., are described and illustrated with special emphasis given to special features in catalog No. 14 now being sent out by the company. These hoists are designed to meet every known requirement of industry. They embody the simplest possible mechanism and it is stated are free of unnecessary fittings and features that would add to the difficulty of maintenance. The catalog also contains in tabulated form the capacities, weights, code words and other information on Hanna air hoists.

CHARCOAL IRON BOILER TUBES.—An interesting book prepared by the Parkesburg Iron Company, Parkesburg, Pa., outlining the development of process of manufacturing charcoal iron boiler tubes is now available on request. By means of illustrations and descriptive matter the entire story of tubes from the raw material to the finished product is explained.

LIGHTING DATA.—Four bulletins on the use of proper lighting facilities in industry have been compiled by the Department of Publicity, Edison Lamp Works, Harrison, N. J. Two of these on lighting legislation and the lighting of steel mills and foundries will be of special interest to our readers.

FLEXIBLE COUPLINGS.—The new flexible coupling is described in a pamphlet issued by the De Laval Steam Turbine Company, Trenton, N. J. This coupling, which has been developed for turbines or other motors geared or direct coupled to pumps, generators, and similar machinery, consists of two opposed flanges mounted on the driving shafts respectively. One flange carries bolts or pins which enter holes bored in the opposing flange, but not coming into metallic contact with the latter, as the driving force is transmitted through steel-lined molded rubber bushings slipped over the pins. All parts are made to limit gages and all similar parts are interchangeable.

INCREASING MARINE PROFITS.—The Diamond Power Specialty Company, Detroit, Mich., is distributing a new marine bulletin, No. 143, which shows different types of Diamond soot blowers applicable to marine boilers of various designs. Complete details of the blowers with photographs of specific installations and their performances are included in the book.

BETHLEHEM OIL ENGINES.—Based on many years' experience in the design of gas engines, the new two-stroke cycle Diesel engine, built by the Bethlehem Steel Company, Bethlehem, Pa., offers an engine which is American throughout and has numerous features which adapt it particularly well to marine service. A description of the engine, with numerous photographs and drawings showing its construction and special features, is given in catalogue "N" which was distributed at the Marine Exposition and is now available on request to the company. In brief, the engine is of the vertical two-stroke cycle single-acting type constructed in units of 4, 6 or 8 cylinders, running at speeds of from 116 revolutions per minute for land power purposes down to 90 revolutions per minute for marine power installations.

Foreign Shipping and Shipbuilding Activities

Two Battleships of Argentine Navy to Be Reconditioned

AMERICAN and foreign shipyards are reported as preparing proposals for the reconditioning of two battleships of the Argentine navy, the *Moreno* and the *Rivadavia*. These ships are understood to be on their way to the United States and a representative of the Argentine Government has already reached New York presumably to take up details regarding the proposed work.

According to the best information obtainable, the ships will be converted to oil burners and undergo a general overhauling, the contracts involving an expenditure of a large sum of money.

Floating Dry Dock Being Designed for Mexico

THE Des Moines Steel Company, Curry Building, Pittsburgh, Pa., is reported as designing a 6,000-ton floating dry-dock for the Government of Mexico, to be used at Vera Cruz. The dock is to have a length of about 320 feet; width, 100 feet, and light draft, 3 feet 6 inches. It is proposed to build the dock at the company's Pittsburgh Works, floating it down the Ohio and Mississippi Rivers to the Gulf of Mexico, and then to Vera Cruz.

Canadian Pacific Will Add Two Ships to Fleet

E. W. Beatty, K. C., president of the Canadian Pacific Railway, recently addressed a meeting of the Vancouver board of trade and announced that his company proposes to add two large modern steamers to its coast fleet, immediately, to take care of increasing tourist traffic. He also announced the early completion of a new pier at the harbor to cost several millions of dollars.

Government of Queensland in Market for Dredge

Bids are being invited by the Government of Queensland, Australia, on a twin-screw stern-wheel bucket hopper dredger, according to United States Consul Romeyn Wormuth, at Newcastle. The dredger is to have a draft not to exceed 13 feet when fully loaded. The specifications call for a hopper capacity of 16,000 cubic feet and dredging depth of 40 feet below water level and a continuous speed, when fully laden and with bunkers full, of 9 knots per hour. A statement of the earliest date at which the dredger can be delivered complete at the Port of Brisbane should accompany the bid.

The single copy of the specifications received by the Industrial Machinery Division of the Department of Commerce has been placed in the New York office of the Bureau

World's Largest Dry Dock Opened By Governor General of Canada

THE mammoth graving dock built for the St. John Dry Dock and Shipbuilding Company, Ltd., St. John, N. B., was formally opened on Monday, October 26, when the steamer *Kongshaven* entered the dock for repairs to her rudder post, which had been carried away a few days previously. The event was witnessed by guests from all over Canada, the United States and England, including among others Lord Byng, the Governor General, of Canada; Grant Hall, vice-president of the Canadian Pacific Railway; Sir Henry Thornton, president of the Canadian National Railways, Sir Joseph Isherwood of London and New York; James French, principal surveyor for Lloyd's in Canada and United States; James B. Craven of Larchmont and New York; and A. MacCorkindale of the Morse Dry Dock and Repair Company, Brooklyn, N. Y. F. M. Ross, manager of the St. John Dry Dock and

Shipbuilding Company, was on hand to greet all the guests and supervise in general all details.

The dimensions of the graving dock are as follows: Extreme length, 1,225 feet; length on keel blocks, 1,150 feet (the dock can be subdivided by an additional caisson, thus making two docks, one 650 feet long and one 500 feet long); width of dock entrance, top, 133 feet; bottom, 125 feet; draft above sill at ordinary spring tides, 42 feet; bottom of dock below sill, 4 feet 6 inches.

The St. John Dry Dock and Shipbuilding Company also has an 1,800-ton marine railway and the industrial buildings comprise a machine shop, plate shop, boiler shop, pattern shop and joiner shop, all of steel and concrete construction, which will soon be fully equipped with adequate machinery for handling the largest job that can be brought into the dry dock.

French Steamship Company Places Order for Twin Screw Motor Passenger Liner

By Our Paris Correspondent

CONSIDERABLE interest has been aroused in France in connection with the order which has just been placed by the big French steamship company, "Services Contractuels des Messageries Maritimes," for a passenger vessel which is to be propelled by two internal combustion engines developing a total power of about 4,500 horsepower. The extreme scarcity of motorships so far under construction in France, which I pointed out in the May issue, is responsible for the stir aroused by this recent development.

So far only one motorship is under construction in French shipyards, the *Camrahn*, a cargo vessel of 11,700 tons deadweight built by the Chantiers de la Loire to the account of the Chargeurs Reunis. The hull of that vessel is still unfinished at Nantes, while the engines have been delivered months ago.

The order for the motorship of the Messageries Maritimes has been placed with the Chantiers de France at Dunkirk. The vessel will be built to the same design as the *Sphinx*, a type of vessel which is run by the company on the Mediterranean lines. But it is noteworthy that the hull only will be built by the Chantiers de France, while the engines will be supplied by either Burmeister & Wain or the Sulzer Bros.

of Foreign and Domestic Commerce, where it may be consulted by interested manufacturers.

Consul Wormuth states that he has been informed that twelve copies of the contract and specifications have been forwarded to the State Engineer, Albany, N. Y., and that another set is available at the office of the trade commissioner for Australia, 44 Whitehall Street, New York, N. Y.

According to recent reports, it is likely that the order will be placed with the latter concern and that the engines will be built at the Saint-Denis (near Paris) works of the French branch of Sulzer Bros. It will be recalled that the engines of the *Camrahn* have been supplied by the same concern which had these engines built at its Winterthur works (Switzerland).

Now that two big French steamship companies have decided on a first experiment of internal combustion engines, there is some speculation as to whether other firms will follow these examples in the near future.

FRENCH LINE TO RESUME CANADIAN SERVICE

It is learned that the French Line has just decided to resume its regular service with Canada, which was suspended at the beginning of the war. The home port, however, is to be Bordeaux instead of Havre as before the war. Two passenger vessels will be placed on this run: the *Roussillon* (ex-German *Goeben*), 8,819 tons gross, and *La Bourdonnais* (ex-German *Scharhorst*), 8,287 tons gross. Calls will be made at Halifax on the outward route of the two vessels which will sail from Bordeaux every 21 days. On the homeward voyages they will call at Vigo before reaching Bordeaux. The first call at Halifax will be made on December 2.

It is noteworthy that so far no French company is running regular passenger and cargo services to Canada; this service is being maintained from Havre by two American companies.

Another interesting development in connection with French shipping is the recent organization of regular services between French ports and Petersburg by the Messageries Maritimes. This is the first resumption of services with Russia.

Marine Construction News of the Month

Ship Contracts—New Ship Concerns and Shipyard Improvements—Terminal Projects—Government Contracts

SHIPBUILDING AND REPAIRS

Tanker Drydocked, Galveston, Tex.—The tanker E. B. Kemp has been drydocked for repairs at Galveston.

Steamship Overhauling, Portland, Ore.—The steamer West Jena, of the Shipping Board, has been drydocked at Portland for overhauling.

Miscellaneous Repairs, Philadelphia, Pa.—The Cramp Shipbuilding yard was awarded miscellaneous repairs to the Norwegian motor tanker Hamlet.

Repairs to Steamer, Charleston, S. C.—Steamship Janelaw has been placed on the ways of the Charleston Dry Dock and Machine Company for repairs.

Damage Repairs, San Francisco, Cal.—The steamer Elizabeth, which recently went ashore at Bandon, Ore., has been taken to San Francisco for drydocking for repairs.

Oil Carrying Barge Launched, Chester, Pa.—The Sun Shipbuilding and Drydock Company has launched a 140-foot, 5,000 barrel oil carrying barge for the New York Central Railroad.

British Tanker Reconditioning, San Pedro, Cal.—The giant British tanker Albertolite has been drydocked at San Pedro to undergo reconditioning preparatory to a cruise to Chile.

British Steamer Repairs, Chester, Pa.—The British steamship Nowshera has been taken to the Sun Shipbuilding and Drydock Company's yards for drydocking and miscellaneous repairs.

Fire Damage, West Coast.—The freighter Diana Dollar, which caught fire off the Mexican coast recently, has suffered damages estimated at \$500,000, according to messages from her master.

Steamer Segvia Repairs, Charleston, S. C.—After having grounded recently while on her way to Europe from Galveston, the steamship Segvia was taken to the Charleston Drydock & Machine Company to undergo repairs.

West Arrow Drydocked, Boston, Mass.—The American steamship West Arrow, recently in collision with the White Star liner Haverford, has been taken to Boston for drydocking for survey. Her forepeak tank was crushed in and five plates broken.

Steamer Drydocked, Newport News, Va.—The Danish steamer Norden, damaged recently by grounding off the Canadian coast, has been taken to the docks of the Newport News Shipbuilding and Dry Dock Company for surveying and repairing.

Ship Repair Revival, Philadelphia, Pa.—A revival in the repair branch of the shipbuilding industry in the Delaware River district has been reported by J. Harry Mull, president of the William Cramp & Sons Ship & Engine Building Company at Philadelphia.

Steamers Drydocked, San Francisco, Cal.—The Government freighter West Montop has been placed on the Bethlehem drydock to have a new tail shaft and other work performed and the tanker China Arrow went on drydock at the same yard for general repairs.

Bids to Be Asked, Boston, Mass.—The steamer City of Rockland, which went ashore on Dix Island while bound from Bath for Boston, has been floated. The Eastern Steamship Lines, Inc., owners, will ask for bids to recondition the vessel, which is said to be badly damaged.

Steamship Drydocked for Repairs, Charleston, S. C.—The Springfield has been withdrawn from the service of the Carolina Company of Charleston and has been drydocked for repairs. It is stated that after repairs are completed the vessel may be reallocated by the Shipping Board.

Raised Vessel to Undergo Repairs, Charleston, W. Va.—The steamship Springfield, recently rammed and sunk by a Clyde Line steamer in St. John's river in Jacksonville, Fla., has been raised and taken to the yard of the Charleston Dry Dock and Machine Company for repairs.

Dredge, Portland, Ore.—The Port of Portland, Spalding Building, is having plans prepared for dredge to be equipped with four 750 horsepower Diesel engines and 30-inch suction and discharge pipe. J. H. Polhemus, general manager; G. B. Hegardt, Stark Street Dock, engineer.

Rudder Test, Bridgeport, Conn.—It has been announced that the Kitchen patent rudder has undergone a successful test aboard the yacht Wanda II off Bridgeport, Conn. The yacht, which is electrically controlled, is said to have stopped during the tests in one and one-half times her length in eighteen seconds from full-speed-ahead motion.

Leviathan to be Drydocked, Boston, Mass.—The Leviathan will be laid up for three months this winter, upon the completion of her next voyage, after her arrival in New York on November 26. She will go to the Commonwealth drydock in Boston after leaving the Shipping Board piers at Hoboken and will return to service in the early spring.

President Wilson Bids, West Coast.—At the opening of tenders for carrying out repairs on the Pacific Mail liner President Wilson the following companies submitted bids: United Engineering, \$1,712; General Engineering, \$2,282; Moore Drydock Company, \$2,293, and Smith & Scanlon, \$3,890. The specifications covered work on her engines.

Ships to Burn Oil.—The Japanese steamship line, Toyo Kisen Kaisha, has decided to convert the Tenyo Maru and the Shinyo Maru, operated on the Transpacific service, into Diesel engine motorships and has ordered the engines from Germany, according to recent London reports, the company having appropriated for their conversion 1,000,000 yen.

Vessel Launched, Newport News, Va.—The City of Birmingham, building at Newport News for the Ocean Steamship Company, has been launched. Her general dimensions are: length over all, 400 feet; beam, 52 feet; depth molded to hurricane deck, 35 feet; draft fully loaded, 18 feet 6 inches. She has a gross tonnage of 6,500 tons, an indicated horsepower of 2,900, and a speed of 12½ knots.

Installation of Radio Finders, West Coast.—Kolster radio direction finders are to be installed on five of the Matson Navigation Company's six-passenger steamers and two of its largest freighters. The H. F. Alexander, of the Admiral Line, was the first Pacific Coast vessel to have a radio direction finder installed. The Admiral Line officials have ordered six more finders to be installed on their coastwise vessels.

Salvage, Pacific Coast.—It has been learned that Merritt, Chapman and Scott have been commissioned by the United States Navy to salvage all available gear, etc., from the seven destroyers which recently went on the rocks during a fog on the California Coast. There is very little or no hope of saving any of the vessels. When the salvage operations are complete, it is expected that the wrecks will be blown up.

Shipyard Work, Chester, Pa.—The Sun Shipbuilding and Drydock Company, Chester, was awarded the work of drydocking the steamship West Inskip and also the Herbert L. Pratt for general repairs. The same company was the successful bidder against the Newport News Shipbuilding Company for the contract to repair the British steamship Nile, which requires drydocking to paint and scrape bottom, with a possibility of renewing her propeller and also the tailshaft.

Shipyard Activities, West Coast.—The General Engineering and Drydock Company submitted the lowest figures on the following work. Government steamer Angel: General Engineering, \$1,212; Han-

lon Drydock Company, \$1,511; Bethlehem Shipbuilding, \$1,653, and the Moore Drydock Company, \$1,704. Prices for work on the Hoven were: General Engineering and Drydock Company, \$1,888; United Engineering Company, \$1,938; Moore, \$2,162, and Bethlehem, \$2,358.

Ship Contracts, New Orleans, La.—The Johnson Iron Works, New Orleans, has been awarded the following work: Tampa Inter-Ocean Steamship Company's steamer Narbo, general repairs, consisting of drydocking, painting, pulling tail shaft and overhauling of auxiliaries; installation of new furnaces in all boilers on steamship Moranzania, of Vacaro Brothers, and general repairs to the West Ira, of Lykes Brothers, consisting of drydocking, painting, and pulling tailshaft.

Diesel Yacht Launched.—According to announcement by Cox & Stevens, designers of the ocean-going Diesel yacht Vanadis, the vessel was successfully launched on November 15 and will be delivered to her owner, C. K. G. Billings, early in 1924. The Vanadis has a length of 240 feet, beam 35 feet, draft 14 feet, and has two Diesel engines developing 1,800 horsepower, which produces a speed of fourteen knots with a cruising radius of 12,000 miles. She is said to be the largest Diesel yacht yet constructed.

Diesel Dredges Launched, Chester, Pa.—The A. McKenzie and the W. L. Marshall were launched on November 19 at the Chester plant of the Sun Shipbuilding Company. These Diesel electric dredges were built by the Sun yard for the engineering corps of the War Department. They will be delivered in January and February. The Dan C. Kingman and the William T. Russell will be launched in March and April. The dredges are 245 feet long, 46 feet beam and 19 feet 6 inches loaded draft, and are of 2,000 deadweight tons each.

Ship Work, Mobile, Ala.—The Alabama Dry Dock & Shipbuilding Company, Mobile, Ala., has been awarded the following work: Steamship Hancock County, renewing of heater tubes and tube sheet and heater installation; Coast Guard cutter Tallapoosa, repairs to collision damage; steamship Shenandoah, engine repairs; steamer Scott, of Mississippi-Warrior Service, boring and fitting two propeller wheels to shaft; steamship Lysefjord, extensive reconditioning; tug Jim Sid, boiler repairs; and a joiner job on the steamer Bay Queen.

Warships Overhauling, Brooklyn, N. Y.—For a general overhauling the battleships Arkansas and Wyoming and the destroyers Goff, Gilmer, J. Paulding, Fox, Barry, Williams, Hatfield, Overton and King have arrived at the Brooklyn Navy Yard. The same yard has obtained several other jobs, including reconditioning of the Shipping Board freighter Aisne and the cutting up of the partly completed battleships South Dakota and Indiana. This work will prevent the lay-off of workman planned for January 1 and will result in hiring additional men, according to the yard.

Dispatch Boat Conversions, South America.—The Bethlehem Shipbuilding Corporation has been awarded the contract for considerable work on two ships of the Aviso class (dispatch boats) for the Argentine navy. Each vessel is equipped with three Thornycroft boilers, the contract calling for the installation of the Bethlehem-Dahl fuel oil burning system with pumps, heaters, strainers, etc. The contract also requires that the boilers be capable of burning any kind of oil on the market and each fireroom is to be fitted as a separate unit. The work will be done at the Argentine navy dock yards.

Repair Contracts, Buffalo, N. Y.—The Buffalo Dry Dock Company is engaged in installing a new wheel and new tail shaft on the steamer Juniata, passenger steamer of the Great Lakes Transit Corporation, and also installing a new wheel on the tug A. C. Dutton, of the Rochester Terminals and Canal Corporation. The Riley Dry Dock Company,

Buffalo, is engaged in the following work: Docking the lake barge Richland Star, of the Benjamin Iron Company, and the tug Saginaw, for minor hull repairs. The same company has completed extensive repairs on the steam barge Mohegan, of the Inland Marine Corporation.

Ship Work, Great Lakes.—The following ship work has been awarded on the Great Lakes: Steamer Malietoa, drydocked at Cleveland for repairs to leak caused by grounding; steamer Conneaut, docked at Ashtabula for repairs to stern tube; steamer Glenisla, drydocked at Collingwood for repairs to collision and grounding damage, and the Berryton, repairing at Port Arthur as a result of collision, at which time the steamer's stern was shoved in several inches, her hawse pipe broken and eighteen plates damaged. The Bennington, which collided with the Berryton, is having temporary repairs at Ecorse. She also has eighteen damaged plates.

Transports to Be Rebuilt, South Atlantic Yards. Two United States Army transports Marne and Oureq, which were turned over to the Shipping Board several months ago to be laid up with the steel fleet in the James River, near Camp Eustis, have been taken to Newport News and Norfolk to be made ready for service. These transports, built during the war for use of the United States Army Transport Service, but not completed in time to transport troops, are 448 feet long with a 58-foot beam and have ample accommodations for passengers and freight. Certain alterations would be necessary to make them suitable for the combination freight and passenger service between New York and London, but officials are of the opinion that that could be done easily, quickly and economically.

Ship Work, San Francisco, Cal.—The General Engineering and Drydock Company has received the following contracts: Associated Oil Company's tanker Kewanee, general repairs, preparatory to undergoing annual inspection; Standard Oil tanker J. A. Moffett, repairs; dredge Big V., extensive alterations, having been idle some time; yacht Shawnee, cleaning, painting and repairs to propeller; steamer Point Arena, reconditioning and drawing tail shaft; Shipping Board steamer Pallas, new line shafting and new spring bearings and general repairs; ferryboat Golden West, drydocking, cleaning and painting and drawing tail shaft; Mexican steamer Bolivar, changing from coal to oil-burning equipment and drawing tail shaft, and the fishing tugs Henrietta and Islander, undergoing miscellaneous repairs and cleaning and painting.

Shipyard Work, West Coast.—The Bethlehem Shipbuilding Corporation, San Francisco, Cal., is engaged in the following work: cleaning, painting and repairing the propeller of the John Line's Swedish motorship San Francisco; cleaning, painting and drawing of the tailshaft on the Shipping Board steamer West Conob; refitting of the starboard propeller on the British motorship Hauraki, of the Hind, Rolph & Company; rudder and propeller repairs to the McCormick Steamship Company's steam schooner Cello; fitting of propellers on the new steam schooner Esther Johnson, of the A. B. Johnson Company, preparatory to undergoing trial trip; hull repairs on the Union Oil Company's tanker La Placencia; miscellaneous repairs to the Mexican, of the American-Hawaiian Line. At present the Bethlehem yards are engaged in reconditioning the American-Hawaiian freighter Dakotan, following her mishap on the Lower California coast some time ago, this work representing an expenditure of approximately \$100,000.

SHIPYARDS AND DRY DOCKS

New Dock Placed in Service, Brooklyn, N. Y.—On November 20 the new 10,000-ton floating dock at the Robins plant of the Todd Shipyards Corporation was placed in service, the tanker Gulfoil of the Gulf Refining Company being the first vessel to be docked. The Robins yard now has a total of two graving docks and four floating docks, bringing the total dock equipment of the Todd Corporation up to twenty-two floating docks and two graving docks.

Company Resumes Activity, Fairfield, Md.—The Union Shipbuilding Company has reorganized its repair department plant at Fairfield, Md., according to word from Baltimore. A new manganese steel hauling chain has been installed on the marine railway drydock, which will raise vessels 415 feet long and of 5,000 tons displacement. The railway is constructed so that vessels are lifted vertically out of the water on practically an even keel while being

hauled on the railway. This is said to eliminate any tendency to strain the ship's structure.

Repair Plant, Wilmington, N. C.—One of the biggest fish oil manufacturing concerns operating along the Atlantic Coast, the Fisheries Products Company, has purchased from a Baltimore concern an extensive portion of the old Carolina shipyard and will operate at the water front site a shipbuilding and repair plant, including extensive machine shops, ship ways, a marine railway and other such equipment necessary for the operation of a first-class shipyard and repair plant. P. H. Hayes, president of the company, stated that his company had purchased it at auction at a cost of \$19,100 all of the unsold portion of the old shipyard and that plans are now under way for the conversion of this property into a shipyard and repair plant, not alone for the building of additional vessels for their fishing fleet and the maintenance of the 24 fishing vessels they now operate, but also for commercial ship work.

PORT IMPROVEMENTS

Retaining Walls, etc., Ohio.—State Highway Department, Columbus, will build new retaining walls at Buckeye Lake in Fairfield and Licking Counties. \$40,000. P. R. Murray, director.

Dredging, etc., Akron, Ohio.—City plans beautifying shores of Summit Lake, by dredging and draining the shore lands and building lagoon system in wider points, etc. \$250,000.

Breakwater, Long Beach, Cal.—Plans are being made by the city for a 3,000-foot breakwater in the vicinity of Pine Avenue Pier, 350,000 tons of rock. C. H. Windham, city manager.

Crane, Newark, N. J.—Riverside Steel Casting Company, Plank Road and Passaic River, is in the market for one 10-ton, 40-foot span electric traveling crane.

Channel Excavation, Toronto, Ont.—Sealed proposals were received on October 15, by A. Beck, chairman, Hydro Electric Power Commission, 190 University Avenue, for excavation of tailrace channel, 20,000 cubic yards of rock.

Repairs Completed, Seattle, Wash.—Repairs to Pier B, Smith's Cove public terminal, the largest ocean dock in the world, have been completed. This pier, more than half a mile long and a city block wide, was damaged by fire.

Contract Awarded, Pittsburg, Kan.—C. Hotz & Son awarded the contract for the first unit grain elevator, 170,000 bushels (capacity to be doubled at later date), to Southwest Engineering Company, Woodruff Building, Springfield, Mo. \$35,000.

Breakwater, Corpus Christi, Tex.—City and Nueces County Navigation, District 1, postponed opening bids and will revise plans and re-advertise for constructing breakwater, protecting levee around turning basin and also dredging in turning basin.

Grain Elevator, Oswego, N. Y.—The Board of Public Works, Albany, awarded the contract for constructing and equipping a grain elevator, five-story, 60 by 213 feet, reinforced-concrete and steel, here, to James Stewart Company, Inc., 30 Church Street, New York. \$1,119,959.

Dock Terminal, etc., Tampa, Fla.—The U. S. Export Chemical Corporation, Krause Building, is having plans prepared for dock terminal elevators and plant for manufacture of double super-phosphate. \$400,000. Address, P. S. Gilchrist, Charlotte, N. C., engineer and architect.

Levees, Clarksdale, Miss.—Sealed proposals were received on October 9 by the Board of Levee Commissioners for Yazoo-Mississippi Delta, for enlarging five-mile old Ward Lake levee, 75,000 cubic yard banquet enlargement, and 10,000 cubic yards of topping. W. L. Head, chief engineer.

Dredging Ship Channel, Tampa, Fla.—U. S. Chemical Export Corporation, Krause Building, is making plans and estimates for dredging ship channel from mouth of Alafia River to main ship channel, 1,000,000 cubic yards excavation. \$400,000. P. S. Gilchrist, Charlotte, N. C., engineer.

Creosoted Piling, etc., Mayersville, Miss.—First and Second Road District, Mayersville, awarded the contract for 2,650 lineal feet of creosoted piling, 6,120 feet of creosoted lumber and 50,000 feet of untreated lumber delivered at Flanton Station, to Creosote Materials Company, Q and C Building, New Orleans, La.

Contract Awarded, Lake Charles, La.—Police Jury, Calcasieu Parish, awarded the contract for navigation channel from Lake Charles to Sabine River, 125 feet wide, 30 feet deep, Section 1, 2,780,000 cubic yards, to United Dredge Company, Galveston, Tex., \$383,640; Section 2, 3,270,000 cubic yards, to Smith Brothers, Alexandria, \$457,800.

Lumber and Piles, New York, N. Y.—E. W. Buckley, commissioner, Department of Purchase, Municipal Building, awarded the contracts for lumber and piles to Department of Docks, to Robinson Lumber Company, New York, \$113,622; Cooney, Eckstein & Company, 302 Broadway, \$9,837; J. A. Maloney & Company, 1170 Broadway, \$4,464.

Beaumont, Tex., Wharf Contract.—The Houston Construction Company, 3102 McKinney Avenue, Houston, Texas, has received the contract to build wharves and to dredge at Beaumont. The project includes the following: Dredging, filling, 75,000 yards; concrete wharf platform, and concrete and timber bulkhead; the total cost of the job being \$267,410.

Waterway Opened, Lake Okeechobee, Fla.—Lake Okeechobee, the second largest body of fresh water in the United States, has been linked with the Atlantic Ocean, sixty-five miles away. The inlet, which extends from the lake to the ocean, was formally opened with fitting exercises and will be navigable to yachts and freighters drawing not more than ten feet of water.

Marine Cables, St. Louis, Mo.—Union Electric Light and Power Company, 12th and Locust Streets, awarded the contract for laying 12 marine cables on Mississippi River bed carrying 12,000 kilowatts of power, connecting Cahokia, Ill., power plant with St. Louis, Mo., station, to Frulin-Colnon Construction Company, Merchants Laclede Building. Engineer's estimate, \$156,000.

Fire Protection System, New Orleans, La.—Sealed proposals were received by the Board of Commissioners of the Port of New Orleans, Suite 200, New Orleans Court Building, on October 11, for a fire protection system at the Sacking Plant of the Public Grain Elevator, comprising extension of existing mains and installation of hydrants and automatic sprinklers. Requisition E. D. 14014. J. H. Walsh, general manager.

Fill, etc., Portland, Ore.—The Port of Portland plans filling Guild Lake, and 1,200 acres adjoining; straightening and deepening Willamette River and Harbor, involving 3,032,760 cubic yards of dredging, \$170,000. Plans are being made for dredge equipped with four 750 horsepower Diesel engines and 30-inch suction and discharge pipe. J. H. Polhemus, Spalding Building, general manager. G. B. Hegardt, Stark Street Dock, engineer.

Buffalo Harbor Improvements.—Major P. S. Reinike, United States District Engineer, Buffalo, N. Y., unfavorably reported to Washington on several recommendations made by the Buffalo City Council, the Buffalo Chamber of Commerce, and the City Planning Commission. Major Reinike's statement says that the middle gap in the breakwater of Buffalo harbor should not be closed as recommended, because the closing would create an unfavorable current through the harbor. He opposes the dredging of the Erie Basin on the ground that it is state property, part of the Barge Canal System, and could not be dredged by the federal government. Major Reinike held that the recommendation of the Lake Carriers' Association that another breakwater be constructed one mile outside the present one, or that twelve feet be added to the height of the present one would create an expense in construction that would not be commensurate with the benefits to be derived. Favorable action is expected on the recommended removal of a triangular point of rock from the entrance of the Black Rock canal and for the widening of the ship canal south of the International Bridge and the removal of shoal opposite Rattlesnake Island in the Niagara River.

GOVERNMENT WORK

Dredging, Bridgeport, Conn.—Sealed proposals were received on October 17 at the office of the U. S. Engineer, Providence, R. I., for dredging in Bridgeport Harbor.

Repairs to Seawall, Hingham, Mass.—Specification 4902—The Bureau of Yards & Docks, Navy Department, Washington, D. C., plans repairs to seawall of slip at Hingham.

Mooring Masts, Washington, D. C.—Specification

4916—The Bureau of Yards & Docks, Navy Department, plans mooring masts at Guantanamo, Cuba; Fort Worth, Tex., and San Diego, Cal.

Bids Rejected for Piers and Wharf, Pearl Harbor, H. T.—Bureau of Yards and Docks, Navy Department, Washington, D. C., rejected bids for reinforced concrete piers and wharf at Submarine Base, here.

Catamarans, etc., Chicago, Ill.—Sealed proposals were received on November 1, at the office of the U. S. Engineer, 537 South Dearborn Street, for catamarans and pipe for 15-inch hydraulic pipe line dredge.

Repairing Jetty, Freeport, Tex.—Sealed proposals were received by the U. S. Engineer Office, Galveston, Tex., on October 31 for repairing Southwest Jetty at Freeport Harbor, Tex. Further information on application.

Steel, etc., Addison, Ky.—U. S. Engineer, P. O. Box 72, Louisville, plans purchasing one carload of 1-inch round soft steel, shop lengths, and 3,200 pounds of c.i. washers, 4 inches in diameter, for Dam 45, Addison, Ky.

Contract Awarded, Norwalk, Conn.—U. S. Engineer Office, Providence, R. I., awarded the contract for dredging 500,000 cubic yards in Norwalk Harbor to J. S. Packard Dredging Company, Turks Head Building, Providence, R. I. \$89,321.

Superstructure, Ludington, Mich.—U. S. Engineer, Milwaukee, awarded the contract for removing timber superstructure and construction of concrete superstructure, Ludington, to S. M. Siesel Company, 160 Ogden Avenue, Milwaukee, Wis. \$149,690.

Dredging, etc., New York, N. Y.—The contract for dredging and rock removal Area 2, New York and New Jersey Channels, has been awarded by the U. S. Engineer Office, 616 Army Building, New York, to E. Breyman, 17 Battery Place. \$577,343.

SHIPPING DEVELOPMENTS

Pacific Mail Steamship Company.—The Pacific Mail Steamship Company has announced a cut in minimum first class rates between New York and Los Angeles, the fare being reduced from \$270 to \$250. The Pacific Mail operates in the intercoastal service.

Mississippi-Warrior Federal Barge Line.—While the Mississippi-Warrior Federal Barge Line earned a net income of \$13,632.27 in the final six months of the fiscal year ended June 30, 1923, it was not sufficient to absorb the losses of the first half of the year and the report sent to Washington shows a loss for the year of \$624,796.62, as compared with a net profit of \$121,017 for 1921-22.

General Steamship Corporation.—Four Diesel-driven vessels, built since the World War and reputed admirably adapted for the demands of the west coast trade, are to be operated by the General Steamship Corporation between Portland and other Pacific Coast ports and those on the western shores of South America, beginning in December, upon the retirement of the Shipping Board fleet at present on the route and which is managed by the same corporation.

Davis Transportation Lines, Inc.—Control of the Charles W. Davis Transportation Company, owning and operating two steamers between New York, New Rochelle, Mamaroneck and other interior points, has been acquired by Matthew C. Brush and George R. Whitlam, heading a group of New York shipping men. The name of the company has been changed to the Davis Transportation Lines, Inc., and plans for increasing the facilities and extension of the service are under way.

New Line to the Orient.—A new steamship line to the Orient, with headquarters at Los Angeles, is being formed by a group of prominent capitalists, according to Lawrence L. Larrabee, Los Angeles attorney, who is acting as general counsel for the company. Articles of incorporation are pending and negotiations are in progress with the Shipping Board for the purchase of three steamers to be placed in the service. Two of these steamers will be 10,000 tons deadweight and will be used for freight only, while the third steamer will be 21,000 tons deadweight and will be used as a combination passenger and freight carrier.

Garland Steamship Corporation.—The Garland Steamship Corporation has announced its withdrawal from the intercoastal trade and the establishment of a trans-Pacific service in January. On the West Coast, San Francisco and Portland will be regular

ports of call and stops will be made in Shanghai, Hongkong and Manila in the Far East. William M. Campion, vice-president of the line, said the new service will start with the William Campion, sailing from Portland early in January, to be followed at fortnightly intervals by the six other ships of the company. The company expects to maintain a regular schedule, with sailings every two weeks from San Francisco and Portland. The executive office will remain in New York, but the principal operating office will be in San Francisco.

American-Hawaiian Steamship Company.—The American-Hawaiian Steamship Company, which operates an intercoastal service between U. S. Atlantic and U. S. Pacific Coast ports, has announced that in addition to ferry car service which has been in operation to New York for some time past in connection with the West Shore, New York, Ontario & Western, Delaware, Lackawanna & Western, and New York, New Haven & Hartford, arrangements have now been completed for ferry car service with the Erie Railroad and New York Central Railroad. When shipments consigned care of American-Hawaiian Steamship Company, Pier 6, Bush Terminal, South Brooklyn, N. Y., move in ferry cars, the only charge incurred is 5 cents per 100 pounds to cover cost of car unloading.

International Mercantile Marine.—An important announcement has just been made by the International Mercantile Marine Company in connection with the service of the Leyland Line between Boston, Liverpool and Manchester. Beginning this month a definite ten days' schedule of sailings will be inaugurated, and in order to maintain this increased service six modern steamers of large carrying capacity have been assigned to the route. These are the steamships Nubian, Darian, Caledonian, Daytonian and Colonian. Each steamer has a carrying capacity for about 10,000 tons of cargo, and most of them are equipped with refrigerating machinery for transporting merchandise of a perishable nature. The new schedule will be inaugurated by the sailing of the Nubian from the port of Boston on December 12 to Manchester and Liverpool, and thereafter there will be sailings at intervals of about ten days.

Canadian Government Merchant Marine, Ltd.—According to an announcement by the Canadian Government Merchant Marine, Ltd., a new monthly direct service between Vancouver, B. C., and Avonmouth, England, via the Panama Canal, was inaugurated by the sailing of the Canadian Winner on October 20. The steamers will carry eastbound grain, canned goods, general cargo and lumber, and westbound iron and steel goods, liquors and general cargo. In inaugurating this new service, it is stated, the company is carrying out its policy of opening up and taking care of new trade routes. The service is also intended to be a factor in the development of the port of Vancouver, utilizing the grain elevator accommodation and other facilities provided at that port. Following the Canadian Winner, the Canadian Prospector sailed from Vancouver on November 20. It is the intention of the Canadian Government Merchant Marine to keep four of their 8,400 deadweight steamers on the new service.
